We would like to dedicate this book to our supervisors: J.M.E. Hyland and J.P. May.

Peter —

My debt to you is evident in everything that I write. I found it astounding that, after each of three or four consecutive close-readings of my thesis in which you suggested complete structural revisions, your advice remained entirely correct every time. You taught me to derive immense pleasure from each comprehensive reappraisal that is demanded whenever deepened mathematical understanding allows a more fundamental narrative to emerge.

By that standard, this text isn't ready yet. Nevertheless, in honor of your 80th birthday, I wanted to dedicate an early draft to you. I'm hoping you'll like the final version.

— Emily

Part I. Basic ∞-Category Theory 1

Chapter 1. ∞-Cosmoi and their Homotopy 2-Categories 3
  1.1. Quasi-Categories 3
  1.2. ∞-Cosmoi 15
  1.3. Cosmological Functors 28
  1.4. The Homotopy 2-Category 33

Chapter 2. Adjunctions, Limits, and Colimits I 41
  2.1. Adjunctions and Equivalences 41
  2.2. Initial and Terminal Elements 49
  2.3. Limits and Colimits 52
  2.4. Preservation of Limits and Colimits 60

Chapter 3. Comma ∞-Categories 69
  3.1. Smothering Functors 70
  3.2. ∞-Categories of Arrows 74
  3.3. Pullbacks of Isofibrations and Right Properness 80
  3.4. The Comma Construction 83
  3.5. Representable Comma ∞-Categories 89
  3.6. Smothering 2-Functors and Fibered Equivalences 100

Chapter 4. Adjunctions, Limits, and Colimits II 111
  4.1. The Universal Property of Adjunctions 112
  4.2. ∞-Categories of Cones 115
  4.3. The Universal Property of Limits and Colimits 119
  4.4. Pointed and Stable ∞-Categories 129

Chapter 5. Fibrations and Yoneda's Lemma 145
  5.1. Cartesian Arrows 146
  5.2. Cartesian Fibrations 152
  5.3. Cartesian Functors 169
  5.4. Cocartesian Fibrations and Bifibrations 173
  5.5. The Representability of Cartesian Fibrations 176
  5.6. Discrete Cartesian Fibrations 180
5.7. The Yoneda Lemma

An Interlude on \( \infty \)-Cosmology

Chapter 6. Exotic \( \infty \)-Cosmoi
  6.1. The \( \infty \)-Cosmos of Isofibrations
  6.2. Flexible Weighted Limits and the Collage Construction
  6.3. Homotopical Properties of Flexible Weighed Limits
  6.4. Cosmologically Embedded \( \infty \)-Cosmoi

Part II. The Calculus of Modules

Chapter 7. Two-Sided Fibrations and Modules
  7.1. Two-Sided Fibrations
  7.2. The \( \infty \)-Cosmos of Two-Sided Fibrations
  7.3. Representable Two-Sided Fibrations and the Yoneda Lemma
  7.4. Modules as Discrete Two-Sided Fibrations

Chapter 8. The Calculus of Modules
  8.1. The Double Category of Two-Sided Fibrations
  8.2. The Virtual Equipment of Modules
  8.3. Composition of Modules
  8.4. Representable Modules

Chapter 9. Formal Category Theory in a Virtual Equipment
  9.1. Liftings and Extensions of Modules
  9.2. Exact Squares
  9.3. Pointwise Right and Left Extensions
  9.4. Formal Category Theory in a Virtual Equipment
  9.5. Limits and Colimits as Pointwise Kan Extensions
  9.6. Weighted Limits and Colimits of \( \infty \)-Categories

Part III. Change of Model and Model Independence

Chapter 10. Cosmological Biequivalences
  10.1. Cosmological Functors
  10.2. Cosmological Biequivalences
  10.3. Cosmological Biequivalences as Change-of-Model Functors
  10.4. Inverse Cosmological Biequivalences

Chapter 11. Model Independence
  11.1. Ad Hoc Model-Invariance of \( \infty \)-Category Theory
  11.2. A Biequivalence of Virtual Equipments
  11.3. First-Order Logic with Dependent Sorts
  11.4. A Language for Model-Independent \( \infty \)-Category Theory

Chapter 12. Applications of Model Independence
  12.1. Opposite \((\infty, 1)\)-Categories and \( \infty \)-Groupoid Cores
12.2. Pointwise Universal Properties 397
12.3. Existence of Pointwise Kan Extensions 410

Appendix of Abstract Nonsense 423

F.5. Adjunctions 616

Bibliography 623
Preface

Mathematical objects of a certain sophistication are frequently accompanied by higher homotopical structures: maps between them might be connected by homotopies, which might then be connected by higher homotopies, which might then be connected by even higher homotopies ad infinitum. The natural habitat for such mathematical objects is not an ordinary 1-category but instead an \(\infty\)-category or, more precisely, an \((\infty, 1)\)-category, with the index “1” referring to the fact that its morphisms above the lowest dimension 1, the homotopies just discussed, are invertible.

Here the homotopies defining the higher morphisms of an \(\infty\)-category are to be regarded as data rather than as mere witnesses to an equivalence relation borne by the 1-dimensional morphisms. This has the consequence that all of the categorical structures in an \(\infty\)-category are weak. Even at the base level of 1-morphisms, composition is not necessarily uniquely defined but instead witnessed by a 2-morphism and associative up to a 3-morphism whose boundary data involves specified 2-morphism witnesses. Thus, diagrams valued in an \(\infty\)-category cannot be said to commute on the nose but are instead interpreted as homotopy coherent.

A fundamental challenge in defining \(\infty\)-categories has to do with giving a precise mathematical meaning of this notion of a weak composition law, not just for the 1-morphisms but also for the morphisms in higher dimensions. Indeed, there is a sense in which our traditional set-based foundations for mathematics are not really suitable for reasoning about \(\infty\)-categories; sets don’t feature prominently in \(\infty\)-categorical data, especially when \(\infty\)-categories are considered in a morally correct fashion as objects that are only well-defined up to equivalence. The morphisms between a fixed pair of objects in an \(\infty\)-category assemble into an \(\infty\)-groupoid, which describes a well-defined homotopy type, though not a well-defined space. When considered up to equivalence, \(\infty\)-categories, like ordinary categories, also don’t have a well-defined set of objects.

Precision is achieved through a variety of models of \((\infty, 1)\)-categories, which are Bourbaki-style mathematical structures that encode infinite-dimensional categories with a weak composition law in which all morphisms above dimension 1 are weakly invertible. In order of appearance, these include simplicial categories, quasi-categories (nee. weak Kan complexes), relative categories, Segal categories, complete Segal spaces, and 1-complicial sets (nee. saturated 1-trivial weak complicial sets), each of which comes with an associated array of naturally-occurring examples. The proliferation of models of \((\infty, 1)\)-categories begs the question of how they might be compared. In the first decades of the 21st century, Bergner, Joyal–Tierney, Verity, Lurie, and Barwick–Kan built various bridges that prove that each of the models listed above “has the same homotopy theory” in the sense of defining the fibrant objects in Quillen equivalent model categories.¹

In parallel with the development of models of \((\infty, 1)\)-categories and the construction of comparisons between them, Joyal pioneered and Lurie and many others expanded a wildly successful project to extend basic category theory from ordinary 1-categories to \((\infty, 1)\)-categories modeled as quasi-categories in

¹A recent book by Bergner surveys all but the last of these models and their interrelationships [14]. For a more whirlwind tour, see [25].
such a way that the new quasi-categorical notions restrict along the standard embedding $\text{Cat} \hookrightarrow \text{QCat}$ to the standard 1-categorical notions. A natural question is then: does this work extend to other models of $(\infty,1)$-categories? And to what extent are basic $\infty$-categorical notions invariant under change of model? For instance, $(\infty,1)$-categories of manifolds are most naturally constructed as complete Segal spaces, so Kazhdan–Varshavsky [63], Boavida de Brito [34], and Rasekh [93, 92] have recently endeavored to redevelop some of the category theory of quasi-categories using complete Segal spaces instead so as to have direct access to constructions and definitions that had previously been introduced only in the quasi-categorical model.

For practical, aesthetic, and moral reasons, the ultimate desire of practitioners is to work “model independently,” meaning that theorems proven with any of the models of $(\infty,1)$-categories would apply to them all, with the technical details inherent to any particular model never entering the discussion. Since all models of $(\infty,1)$-categories “have the same homotopy theory” the general consensus is that the choice of model should not matter greatly, but one obstacle to proving results of this kind is that, to a large extent, precise versions of the categorical definitions that have been established for quasi-categories had not been given for the other models. In cases where comparable definitions do exist in different models, an ad-hoc heuristic proof of model-invariance of the categorical notion in question can typically be supplied, with details to be filled in by experts fluent in the combinatorics of each model, but it would be more reassuring to have a systematic method of comparing the category theory of $(\infty,1)$-categories in different models via arguments that are somewhat closer to the ground.

**Aims of this text**

In this text we develop the theory of $\infty$-categories from first principles in a model-independent fashion using a common axiomatic framework that is satisfied by a variety of models. In contrast with prior “analytic” treatments of the theory of $\infty$-categories — in which the central categorical notions are defined in reference to the coordinates of a particular model — our approach is “synthetic,” proceeding from definitions that can be interpreted simultaneously in many models to which our proofs then apply. While synthetic, our work is not schematic or hand-wave, with the details of how to make things fully precise left to “the experts” and turtles all the way down.² Rather, we prove our theorems starting from a short list of clearly-enumerated axioms, and our conclusions are valid in any model of $\infty$-categories satisfying these axioms.

The synthetic theory is developed in any $\infty$-cosmos, which axiomatizes the universe in which $\infty$-categories live as objects. So that our theorem statements suggest their natural interpretation, we recast $\infty$-category as a technical term, to mean an object in some (typically fixed) $\infty$-cosmos. Several models of $(\infty,1)$-categories are $\infty$-categories in this sense, but our $\infty$-categories also include certain models of $(\infty,n)$-categories as well as fibered versions of all of the above. Thus each of these

²A less rigorous “model-independent” presentation of $\infty$-category theory might confront a problem of infinite regress, since infinite-dimensional categories are themselves the objects of an ambient infinite-dimensional category, and in developing the theory of the former one is tempted to use the theory of the latter. We avoid this problem by using a very concrete model for the ambient $(\infty,2)$-category of $\infty$-categories that arises frequently in practice and is designed to facilitate relatively simple proofs. While the theory of $(\infty,2)$-categories remains in its infancy, we are content to cut the Gordian knot in this way.

³Quasi-categories, complete Segal spaces, Segal categories, and 1-complicial sets (naturally marked quasi-categories) all define the $\infty$-categories in an $\infty$-cosmos.

⁴$\Theta_n$-spaces, iterated complete Segal spaces, and $n$-complicial sets also define the $\infty$-categories in an $\infty$-cosmos, as do (nee. weak) complicial sets, a model for $(\infty,\infty)$-categories. We hope to add other models of $(\infty,n)$-categories to this list.
objects are \(\infty\)-categories in our sense and our theorems apply to all of them.\(^5\) This usage of the term “\(\infty\)-categories” is meant to interpolate between the classical one, which refers to any variety of weak infinite-dimensional categories, and the common one, which is often taken to mean quasi-categories or complete Segal spaces.

Much of the development of the theory of \(\infty\)-categories takes place not in the full \(\infty\)-cosmos but in a quotient that we call the homotopy 2-category, the name chosen because an \(\infty\)-cosmos is something like a category of fibrant objects in an enriched model category and the homotopy 2-category is then a categorification of its homotopy category. The homotopy 2-category is a strict 2-category — like the 2-category of categories, functors, and natural transformations\(^6\) — and in this way the foundational proofs in the theory of \(\infty\)-categories closely resemble the classical foundations of ordinary category theory except that the universal properties they characterize, e.g. when a functor between \(\infty\)-categories defines a cartesian fibration, are slightly weaker than in the familiar case of strict 1-categories.

In Part I, we define and develop the notions of equivalence and adjunction between \(\infty\)-categories, limits and colimits in \(\infty\)-categories, cartesian and cocartesian fibrations and their discrete variants, and prove an external version of the Yoneda lemma, with the majority of these results developed from the comfort of the homotopy 2-category. In an interlude, we digress into abstract \(\infty\)-cosmology to give a more careful account of the full class of limit constructions present in any \(\infty\)-cosmos. This analysis is used to develop further examples of \(\infty\)-cosmoi, whose objects are pointed \(\infty\)-categories, or stable \(\infty\)-categories, or cartesian or cocartesian fibrations in a given \(\infty\)-cosmos.\(^7\)

What’s missing from this basic account of the category theory of \(\infty\)-categories is a satisfactory treatment of the “hom” bifunctor associated to an \(\infty\)-category, which is the prototypical example of what we call a module. In Part II, we develop the calculus of modules between \(\infty\)-categories and apply this to define and study pointwise Kan extensions. This will give us an opportunity to repackage universal properties proven in Part I as parts of the “formal category theory” of \(\infty\)-categories.

This work is all “model-agnostic” in the sense of being blind to details about the specifications of any particular \(\infty\)-cosmos. In Part III we prove that the category theory of \(\infty\)-categories is also “model-independent” in a precise sense: all categorical notions are preserved, reflected, and created by any “change-of-model” functor that defines what we call a biequivalence. This model-independence theorem is stronger than our axiomatic framework might initially suggest in that it also allows us to transfer theorems proven using analytic techniques to all biequivalent \(\infty\)-cosmoi. For instance, the four \(\infty\)-cosmoi whose objects model \((\infty,1)\)-categories are all biequivalent. It follows that the analytically-proven theorems about quasi-categories from [74] transfer to complete Segal spaces, and vice versa. We conclude this part with several applications of this transfer principle. For instance, §12.2 discusses various “pointwise-determined” universal properties that hold in \(\infty\)-cosmoi whose objects are \((\infty,1)\)-categories, which we conclude by first proving these results for quasi-categories using analytical techniques.

The ideal reader might already have some acquaintance with enriched category theory, 2-category theory, and abstract homotopy theory so that the constructions and proofs with antecedents in these

\(^5\)This may seem like sorcery but in some sense is really just the Yoneda lemma. To a close approximation, an \(\infty\)-cosmos is a “category of fibrant objects enriched over quasi-categories.” When the Joyal–Lurie theory of quasi-categories is expressed in a sufficiently categorical way, it extends to encompass analogous results for the corresponding “representably defined” notions in a general \(\infty\)-cosmos.

\(^6\)In fact this is another special case: there is an \(\infty\)-cosmos whose objects are ordinary categories and its homotopy 2-category is the usual category of categories, functors, and natural transformations.

\(^7\)The impatient reader could skip this interlude and take on faith that any \(\infty\)-cosmos begets various other \(\infty\)-cosmoi without compromising their understanding of what follows—though they would miss out on some fun.
traditions will be familiar. Because ∞-categories are of interest to mathematicians with a wide variety of backgrounds, we review all of the material we need on each of these topics in Appendices A, B, and C, respectively. Some basic facts about quasi-categories first proven by Joyal are needed to establish the corresponding features of general ∞-cosmoi in Chapter 1. We state all of these results in §1.1 but defer the proofs that require a lengthy combinatorial digression to Appendix D, where we also introduce \( n \)-complisical sets, a model of \((\infty, n)\)-categories for any \( 0 \leq n \leq \infty \). The proofs that many examples of \( \infty \)-cosmoi appear “in the wild” can be found in Appendix E, where we also present general techniques that the reader might use to find even more examples. The final appendix addresses a crucial bit of unfinished business. Importantly, the synthetic theory developed in the \( \infty \)-cosmos of quasi-categories is fully compatible with the analytic theory developed by Joyal, Lurie, and many others. This is the subject of Appendix F.

Acknowledgments

The first draft of much of this material was written over the course of a semester-long topics course taught at Johns Hopkins in the Spring of 2018 and benefitted considerably from the perspicuous questions asked during lecture by Qingci An, Thomas Brazelton, tslil clingman, Daniel Fuentes-Keuthan, Aurel Malapani-Scala, Mona Merling, David Myers, Apurv Nakade, Martina Rovelli, and Xiuyan Wang. Further revisions were made during the 2018 MIT Talbot Workshop on the model-independent theory of ∞-categories, organized by Eva Belmont, Calista Bernard, Inbar Klang, Morgan Opie, and Sean Pohorence, with Haynes Miller serving as the faculty sponsor. We were inspired by compelling lectures given at that workshop by Timothy Campion, Kevin Carlson, Kyle Ferendo, Daniel Fuentes-Keuthan, Joseph Helfer, Paul Lessard, Lyne Moser, Emma Phillips, Nima Rasekh, Martina Rovelli, Maru Sarazola, Matthew Weatherley, Jonathan Weinberger, Laura Wells, and Liang Ze Wong as well as by myriad discussions with Elena Dimitriadis Bermejo, Luciana Basualdo Bonatto, Olivia Borghi, Tai-Danae Bradley, Tejas Devanur, Aras Ergus, Matthew Feller, Sina Hazratpour, Peter James, Zhulin Li, David Myers, Maximilien Péroux, Mitchell Riley, Luis Scoccola, Brandon Shapiro, Pelle Steffens, Raffael Stenzel, Paula Verdugo, and Marco Vergura.

John Bourke suggested Lemma 2.1.11, which unifies the proofs of several results concerning the 2-category theory of adjunctions. Denis-Charles Cisinski drew our attention to an observation of André Joyal that appears as Exercise 4.2.iii. Omar Antolín-Camarena told us about condition (iii) of Theorem 4.4.12, which turns out to be the most expeditious characterization of stable ∞-categories with which to prove that they assemble into an ∞-cosmos in Proposition 6.4.15. Gabriel Drummond-Cole encouraged us to do some much needed restructuring of Chapter 5. Anna Marie Bohmann suggested Exercise 8.2.i. tslil clingman pointed us to an observation by Tom Leinster, which inspired Exercise 8.3.ii. The presentation and organization in Chapter 9 was greatly improved by observations of Kevin Carlson, who inspired a reorganization, and David Myers, who first stated the result appearing as Proposition 9.1.8. The material on the groupoid core of an \((\infty, 1)\)-category was informed by discussions with Alexander Campbell and Yuri Sulyma, the latter of whom developed much of this material independently (and first) while working on his PhD thesis. Alexander Campbell was consulted several times during the writing of Appendix A, in particular regarding the subtle interaction between change-of-enrichment functors and underlying categories, and also alerted us to the \( \infty \)-cosmos of \( n \)-quasi-categories appearing in Proposition E.3.3 and supplied its proof. Naruki Masuda caught several typos and inconsistencies in Appendix D.

tslil clingman suggested a better way to typeset proarrows in the virtual equipment, greatly improving the displayed diagrams in Chapter 8. Doug Ravenel has propogated the use of the character

Finally, the authors are grateful to financial support provided by the National Science Foundation for support via grants DMS-1551129 and DMS-1652600, the Australian Research Council via the grant DP160101519, and the Johns Hopkins Catalyst and Frontier Award programs. We also wish to thank the Department of Mathematics at Johns Hopkins University and the Centre of Australian Category Theory at Macquarie University for hosting our respective visits.
Part I

Basic $\infty$-Category Theory
In this chapter, we introduce the framework within which we will develop the formal category theory of $\infty$-categories, which goes by the name of an $\infty$-cosmos. Informally, an $\infty$-cosmos is an $(\infty, 2)$-category—that is, a category enriched over $(\infty, 1)$-categories—that is equipped with $(\infty, 2)$-categorical limits, whose objects are $\infty$-categories in some model. To focus this abstract theory on its intended interpretation, we recast “$\infty$-category” as a technical term, reserved to mean an object of some $\infty$-cosmos.

Rather surprisingly, we are able to use a very strict notion of “$(\infty, 2)$-category with $(\infty, 2)$-categorical limits,” defining an $\infty$-cosmos to be a particular type of simplicially-enriched category and modeling the $(\infty, 2)$-categorical limits by strictly-defined simplicially-enriched limits, because so many examples satisfy these axioms. More precisely, an $\infty$-cosmos is a category enriched over quasi-categories, these being a model of $(\infty, 1)$-categories defined as a particular class of simplicial sets. The $(\infty, 2)$-categorical limits are defined as limits of diagrams involving a specified class of maps called isofibrations, which have no intrinsic homotopical meaning—in the sense that any functor between $\infty$-categories is equivalent to an isofibration—but allow us to consider strictly commuting diagrams.

In §1.1, we introduce quasi-categories, reviewing the classical results that will be needed to show that quasi-categories themselves assemble into an $\infty$-cosmos, providing the prototypical example. General $\infty$-cosmoi are defined in §1.2, where several examples are given and a number of basic results are proven. In §1.3, we turn our attention to cosmological functors between $\infty$-cosmoi, which preserve all of the defining structure. Cosmological functors serve dual purposes, on the one hand providing technical simplifications in many proofs, and then later on serving as the “change of model” functors that establish the model independence of $\infty$-category theory.

Finally, in 1.4, we introduce a strictly defined 2-category whose objects are $\infty$-categories, whose 1-cells are the $\infty$-functors between them, and whose 2-cells define $\infty$-natural transformations between these. Any $\infty$-cosmos has a 2-category of this sort, which we refer to as the homotopy 2-category of the $\infty$-cosmos. In fact, the reader who is particularly impatient to get on to the development of the category theory of $\infty$-categories can skip this chapter in its entirety, taking the existence of the homotopy 2-category for granted, and proceed straight to Chapter 2.

1.1. Quasi-Categories

Before introducing an axiomatic framework that will allow us to develop $\infty$-category theory in general, we first consider one model in particular: namely, quasi-categories, which were introduced in 1973 by Boardman and Vogt [20] in their study of homotopy coherent diagrams. Ordinary 1-categories give examples of quasi-categories via the construction of Definition 1.1.4. Joyal first undertook the task of extending 1-category theory to quasi-categories in [59] and [61] and in several unpublished draft book manuscripts. The majority of the results in this section are due to him.
1.1.1. NOTATION (the simplex category). Let $\Delta$ denote the simplex category of finite non-empty ordinals $[n] = \{0 < 1 < \cdots < n\}$ and order-preserving maps. These include in particular the

elementary face operators $[n-1] \xrightarrow{\delta_i} [n] \quad 0 \leq i \leq n$

elementary degeneracy operators $[n+1] \xrightarrow{\sigma_i} [n] \quad 0 \leq i \leq n$

whose images respectively omit and double up on the element $i \in [n]$. Every morphism in $\Delta$ factors uniquely as an epimorphism followed by a monomorphism; these epimorphisms, the degeneracy operators, decompose as composites of elementary degeneracy operators, while the monomorphisms, the face operators, decompose as composites of elementary face operators.

The category of simplicial sets is the category $sSet := \text{Set}^{\Delta^\text{op}}$ of presheaves on the simplex category. We write $\Delta[n]$ for the standard $n$-simplex, the simplicial set represented by $[n] \in \Delta$, and $\Lambda^k[n] \subset \partial \Delta[n] \subset \Delta[n]$ for its $k$-horn and boundary sphere respectively. The sphere $\partial \Delta[n]$ is the simplicial subset generated by the codimension-one faces of the $n$-simplex, while the horn $\Lambda^k[n]$ is the further simplicial subset that omits the face opposite the vertex $k$.

Given a simplicial set $X$, it is conventional to write $X_n$ for the set of $n$-simplices, defined by evaluating at $[n] \in \Delta$. By the Yoneda lemma, each $n$-simplex $x \in X_n$ corresponds to a map of simplicial sets $x : \Delta[n] \to X$. Accordingly, we write $x \cdot \delta^i$ for the $i$th face of the $n$-simplex, an $(n-1)$-simplex classified by the composite map

$$\Delta[n-1] \xrightarrow{\delta^i} \Delta[n] \xrightarrow{x} X.$$ 

Geometrically, $x \cdot \delta^i$ is the “face opposite the vertex $i$” in the $n$-simplex $x$.

Since the morphisms of $\Delta$ are generated by the elementary face and degeneracy operators, the data of a simplicial set $X$ is often presented by a diagram

$$\cdots \quad X_3 \xleftarrow{\sigma_2} X_2 \xleftarrow{\sigma_1} X_1 \xleftarrow{\sigma_0} X_0,$$

identifying the sets of $n$-simplices for each $[n] \in \Delta$ as well as the (contravariant) actions of the elementary operators, conventionally denoted using subscripts rather than superscripts.

1.1.2. DEFINITION (quasi-category). A quasi-category is a simplicial set $A$ in which any inner horn can be extended to a simplex, solving the displayed lifting problem:

$$\Lambda^k[n] \longrightarrow A \quad \text{for} \quad n \geq 2, \; 0 < k < n. \quad (1.1.3)$$

Quasi-categories were first introduced by Boardman and Vogt [20] under the name “weak Kan complexes,” a Kan complex being a simplicial set admitting extensions as in (1.1.3) along all horn

---

4This presentation is also used for more general simplicial objects valued in any category.
inclusions $n \geq 1, 0 \leq k \leq n$. Since any topological space can be encoded as a Kan complex, in this way spaces provide examples of quasi-categories.

Categories also provide examples of quasi-categories via the nerve construction.

1.1.4. DEFINITION (nerve). The category $\textbf{Cat}$ of 1-categories embeds fully faithfully into the category of simplicial sets via the nerve functor. An $n$-simplex in the nerve of a 1-category $C$ is a sequence of $n$ composable arrows in $C$, or equally a functor $\mathbb{n} + 1 \to C$ from the ordinal category $\mathbb{n} + 1 := [n]$ with objects $0, \ldots, n$ and a unique arrow $i \to j$ just when $i \leq j$.

The map $[n] \mapsto \mathbb{n} + 1$ defines a fully faithful embedding $\Delta \hookrightarrow \textbf{Cat}$. From this point of view, the nerve functor can be described as a “restricted Yoneda embedding” which carries a category $C$ to the restriction of the representable functor $\text{hom}(-, C)$ to the image of this inclusion. More general “nerve-type constructions” are described in Exercise 1.1.i.

1.1.5. REMARK. The nerve of a category $C$ is 2-coskeletal as a simplicial set, meaning that every sphere $\partial \Delta[n] \to C$ with $n \geq 3$ is filled uniquely by an $n$-simplex in $C$ (see Definition C.5.2). Note a sphere $\partial \Delta[2] \to C$ extends to a 2-simplex if and only if that arrow along its diagonal edge is the composite of the arrows along the edges in the inner horn $\Lambda^1[2] \subset \partial \Delta[2] \to C$. The simplices in dimension 3 and above witness the associativity of the composition of the path of composable arrows found along their spine, the 1-skeletal simplicial subset formed by the edges connecting adjacent vertices. In fact, as suggested by the proof of Proposition 1.1.6, any simplicial set in which inner horns admit unique fillers is isomorphic to the nerve of a 1-category; see Exercise 1.1.iv.

We decline to introduce explicit notation for the nerve functor, preferring instead to identify 1-categories with their nerves. As we shall discover the theory of 1-categories extends to $\infty$-categories modeled as quasi-categories in such a way that the restriction of each $\infty$-categorical concept along the nerve embedding recovers the corresponding 1-categorical concept. For instance, the standard simplex $\Delta[n]$ is isomorphic to the nerve of the ordinal category $\mathbb{n} + 1$, and we frequently adopt the latter notation — writing $\mathbb{1} := \Delta[0], \mathbb{2} := \Delta[1], \mathbb{3} := \Delta[2], \ldots$ — to suggest the correct categorical intuition.

To begin down this path, we must first verify the assertion that has implicitly just been made:

1.1.6. PROPOSITION (nerves are quasi-categories). Nerves of categories are quasi-categories.

PROOF. Via the isomorphism $C \cong \text{cosk}_2 C$ and the adjunction $\text{sk}_2 \dashv \text{cosk}_2$ of C.5.2, the required lifting problem displayed below-left transposes to the one displayed below-right

\[
\begin{array}{ccc}
\Lambda^k[n] & \longrightarrow & C \cong \text{cosk}_2 C \\
\downarrow & & \downarrow \\
\Delta[n] & \leftrightarrow & \text{sk}_2 \Delta[n] \\
\end{array}
\]

The functor $\text{sk}_2$ replaces a simplicial set by its 2-skeleton, the simplicial subset generated by the simplices of dimension at most two. For $n \geq 4$, the inclusion $\text{sk}_2 \Lambda^k[n] \hookrightarrow \text{sk}_2 \Delta[n]$ is an isomorphism.

²The total singular complex construction defines a functor from topological spaces to simplicial sets that is an equivalence on their respective homotopy categories — weak homotopy types of spaces correspond to homotopy equivalence classes of Kan complexes [90, §11.2]. The left adjoint constructed by Exercise 1.1.i “geometrically realizes” a simplicial set as a topological space.
in which case the lifting problems on the right admit (unique) solutions. So it remains only to solve the lifting problems on the left in the cases $n = 2$ and $n = 3$.

To that end consider

\[
\begin{align*}
\Lambda^1[2] &\to C \\
\Lambda^1[3] &\to C \\
\Lambda^2[3] &\to C
\end{align*}
\]

An inner horn $\Lambda^1[2] \to C$ defines a composable pair of arrows in $C$; an extension to a 2-simplex exists precisely because any composable pair of arrows admits a (unique) composite.

An inner horn $\Lambda^1[3] \to C$ specifies the data of three composable arrows in $C$, as displayed in the diagram below, together with the composites $gf$, $hg$, and $(hg)f$.

\[
\begin{array}{c}
c_0 \\
f \downarrow \quad g \downarrow \\
c_2 \\
c_1 \quad (hg)f \downarrow \\
c_3
\end{array}
\]

Because composition is associative, the arrow $(hg)f$ is also the composite of $gf$ followed by $h$, which proves that the 2-simplex opposite the vertex $c_1$ is present in $C$; by 2-coskeletality, the 3-simplex filling this boundary sphere is also present in $C$. The filler for a horn $\Lambda^2[3] \to C$ is constructed similarly.

1.1.7. DEFINITION (homotopy relation on 1-simplices). A parallel pair of 1-simplices $f, g$ in a simplicial set $X$ are homotopic if there exists a 2-simplex whose boundary takes either of the following forms

\[
\begin{align*}
\sigma_0 &\quad \sigma_1 \\
\delta_0 &\quad \delta_1
\end{align*}
\]

or if $f$ and $g$ are in the same equivalence class generated by this relation.

In a quasi-category, the relation witnessed by either of the types of 2-simplex on display in (1.1.8) is an equivalence relation and these equivalence relations coincide:

1.1.9. LEMMA (homotopic 1-simplices in a quasi-category). Parallel 1-simplices $f$ and $g$ in a quasi-category are homotopic if and only if there exists a 2-simplex of any or equivalently all of the forms displayed in (1.1.8).

PROOF. Exercise 1.1.ii. □

1.1.10. DEFINITION (the homotopy category [43, §2.4]). By 1-truncating, any simplicial set $X$ has an underlying reflexive directed graph

\[
\begin{array}{c}
X_1 \\
\delta_1 \\
\delta_0
\end{array}
\]

the 0-simplices of $X$ defining the objects and the 1-simplices defining the arrows. By convention, the source of an arrow $f \in X_1$ is its 0th face $f \cdot \delta^1$ (the face opposite 1) while the target is its 1st face $f \cdot \delta^0$ (the face opposite 0). The free category on this reflexive directed graph has $X_0$ as its object set,
degenerate 1-simplices serving as identity morphisms, and non-identity morphisms defined to be finite directed paths of non-degenerate 1-simplices. The homotopy category \( hX \) of \( X \) is the quotient of the free category on its underlying reflexive directed graph by the congruence\(^1\) generated by imposing a composition relation \( h = g \circ f \) witnessed by 2-simplices

\[
\begin{array}{c}
  f & \xrightarrow{x_1} & g \\
  x_0 & \xrightarrow{h} & x_2
\end{array}
\]

This relation implies in particular that homotopic 1-simplices represent the same arrow in the homotopy category.

The homotopy category of the nerve of a 1-category is isomorphic to the original category, as the 2-simplices in the nerve witness all of the composition relations satisfied by the arrows in the underlying reflexive directed graph. Indeed, the natural isomorphism \( hC \cong C \) forms the counit of an adjunction, embedding \( \mathbf{Cat} \) as a reflective subcategory of \( \mathbf{sSet} \).

1.1.11. PROPOSITION. The nerve embedding admits a left adjoint, namely the functor which sends a simplicial set to its homotopy category:

\[
\begin{array}{rcl}
\mathbf{Cat} & \xhookrightarrow{h} & \mathbf{sSet}
\end{array}
\]

In fact, the adjunction of Proposition 1.1.11 exists for formal reasons; see Exercise 1.1.i. Nevertheless, a direct proof can be enlightening:

PROOF. For any simplicial set \( X \), there is a natural map \( X \rightarrow hX \) from \( X \) to the nerve of its homotopy category; since nerves are 2-coskeletal, it suffices to define the map \( \text{sk}_2 X \rightarrow hX \), and this is given immediately by the construction of Definition 1.1.10. Note that the quotient map \( X \rightarrow hX \) becomes an isomorphism upon applying the homotopy category functor and is already an isomorphism whenever \( X \) is the nerve of a category. Thus the adjointness follows from Lemma B.4.2 or by direct verification of the triangle equalities. \( \square \)

The homotopy category of a quasi-category admits a simplified description.

1.1.12. LEMMA (the homotopy category of a quasi-category). If \( A \) is a quasi-category then its homotopy category \( hA \) has

- the set of 0-simplices \( A_0 \) as its objects
- the set of homotopy classes of 1-simplices \( A_1 \) as its arrows
- the identity arrow at \( a \in A_0 \) represented by the degenerate 1-simplex \( a \cdot \sigma^0 \in A_1 \)
- a composition relation \( h = g \circ f \) in \( hA \) if and only if, for any choices of 1-simplices representing these arrows, there exists a 2-simplex with boundary

\[
\begin{array}{c}
  f & \xrightarrow{a_1} & g \\
  a_0 & \xrightarrow{h} & a_2
\end{array}
\]

PROOF. Exercise 1.1.iii. \( \square \)

\(^1\)A relation on parallel pairs of arrows of a 1-category is a congruence if it is an equivalence relation that is closed under pre- and post-composition: if \( f \sim g \) then \( hfk \sim hgz \).
1.1.13. Definition (isomorphisms in a quasi-category). A 1-simplex in a quasi-category is an isomorphism just when it represents an isomorphism in the homotopy category. By Lemma 1.1.12 this means that \( f : a \to b \) is an isomorphism if and only if there exists a 1-simplex \( f^{-1} : b \to a \) together with a pair of 2-simplices

\[
\begin{array}{ccc}
  f & b \\
  \downarrow & \searrow \hspace{1cm} & a \\
  a & \downarrow & f^{-1} \\
  b & \to & a
\end{array}
\]

The properties of the isomorphisms in a quasi-category are most easily proved by arguing in a slightly different category where simplicial sets have the additional structure of a “marking” on a specified subset of the 1-simplices containing the degenerate 1-simplices; maps of these so-called marked simplicial sets must then preserve the markings. For instance, each quasi-category has a natural marking, where the marked 1-simplices are exactly the isomorphisms. Since the property of being an isomorphism in a quasi-category is witnessed by the presence of 2-simplices with a particular boundary, every map between quasi-categories preserves isomorphisms, inducing a map of the corresponding naturally marked quasi-categories. Because marked simplicial sets will seldom appear outside of the proofs of certain combinatorial lemmas about the isomorphisms in quasi-categories, we save the details for Appendix D.

Let us now motivate the first of several results proven using marked techniques. A quasi-category \( A \) is defined to have extensions along all inner horns. But if in an outer horn \( \Lambda^0[n] \to A \) or \( \Lambda^n[2] \to A \), the initial or final edges, respectively, map to isomorphisms in \( A \), then intuitively a filler should exist

\[
\begin{array}{ccc}
  f & a_1 \\
  \downarrow & \to \hspace{1cm} & \downarrow \\
  a_0 & \to & h^{-1} \\
  g & \hspace{1cm} & a_2 \\
  \hline
  g^{-1}h & a_1 \\
  \downarrow & \to \hspace{1cm} & \downarrow \\
  a_0 & \to & h \\
  f & \hspace{1cm} & a_2
\end{array}
\]

and similarly for the higher-dimensional outer horns.

(i) Let \( A \) be a quasi-category. Then for \( n \geq 2 \) any outer horns

\[
\begin{array}{ccc}
  \Lambda^0[n] & \xrightarrow{g} & A \\
  \downarrow & \searrow \hspace{1cm} & \downarrow \\
  \Delta[n] & \to & \Lambda^n[n] \\
  \hline
  \Lambda^n[n] & \xrightarrow{h} & A \\
  \downarrow & \searrow \hspace{1cm} & \downarrow \\
  \Delta[n] & \to & \Delta[n]
\end{array}
\]

in which the edges \( g|_{[0,1]} \) and \( h|_{[n-1,n]} \) are isomorphisms admit fillers.\(^5\)

(ii) Let \( A \) and \( B \) be quasi-categories and \( f : A \to B \) a map that lifts against the inner horn inclusions. Then for \( n \geq 2 \) any outer horns

\[
\begin{array}{ccc}
  \Lambda^0[n] & \xrightarrow{g} & A \\
  \downarrow & \searrow \hspace{1cm} & \downarrow \\
  \Delta[n] & \to & \Lambda^n[n] \\
  \hline
  \Lambda^n[n] & \xrightarrow{h} & A \\
  \downarrow & \searrow \hspace{1cm} & \downarrow \\
  \Delta[n] & \to & \Delta[n]
\end{array}
\]

\(^4\) Joyal refers to these maps as “isomorphisms” while Lurie refers to them as “equivalences.” We prefer, wherever possible, to use the same term for \( \infty \)-categorical concepts as for the analogous 1-categorical ones.

\(^5\) Fillers also exist in the case \( n = 1 \) in the absence of any hypothesis, as required 1-simplices in \( A \) can be chosen to be degenerate.
in which the edges $g|_{[0,1]}$ and $h|_{[n-1,n]}$ are isomorphisms admit fillers.

The proof of Proposition 1.1.14 requires clever combinatorics, due to Joyal, and is deferred to Proposition D.4.5 and Theorem D.4.19 in Appendix D.⁶ Here, we enjoy its myriad consequences. Immediately:

1.1.15. COROLLARY. A quasi-category is a Kan complex if and only if its homotopy category is a groupoid.

PROOF. If the homotopy category of a quasi-category is a groupoid, then all of its 1-simplices are isomorphisms, and Proposition 1.1.14 then implies that all inner and outer horns have fillers. Thus, the quasi-category is a Kan complex. Conversely, in a Kan complex, all outer horns can be filled and in particular fillers for the horns displayed in Definition 1.1.13 can be used to construct left and right inverses for any 1-simplex. □

A quasi-category contains $A$ a canonical maximal sub Kan complex $A^\approx$, the simplicial subset spanned by those 1-simplices that are isomorphisms. Just as the arrows in a quasi-category $A$ are represented by simplicial maps $\Delta[1] \to A$ whose domain is the nerve of the free-living arrow, the isomorphisms in a quasi-category can be represented by diagrams $\Delta[1] \to A$ whose domain is the free-living isomorphism:

1.1.16. COROLLARY. An arrow $f$ in a quasi-category $A$ is an isomorphism if and only if it extends to a homotopy coherent isomorphism

$$\begin{array}{ccc}
\Delta[1] & \overset{f}{\longrightarrow} & A \\
\downarrow & & \downarrow \\
\Delta[0] & \longrightarrow & A^\approx \subset A
\end{array}$$

PROOF. If $f$ is an isomorphism, the map $f: \Delta[1] \to A$ lands in the maximal sub Kan complex contained in $A$:

$$\begin{array}{ccc}
\Delta[1] & \overset{f}{\longrightarrow} & A^\approx \subset A \\
\downarrow & & \downarrow \\
\Delta[0] & \longrightarrow & A
\end{array}$$

By Exercise 1.1.v, the inclusion $\Delta[1] \hookrightarrow \Delta[0]$ can be expressed as a sequential composite of outer horn inclusions. Since $A^\approx$, this shows that the required extension exists, and in fact lands in $A^\approx \subset A$. □

The category of simplicial sets, like any category of presheaves, is cartesian closed. By the Yoneda lemma and the defining adjunction, an $n$-simplex in the exponential $Y^X$ corresponds to a simplicial map $X \times \Delta[n] \to Y$, and its faces and degeneracies are computed by precomposing in the simplex variable. Our aim is now to show that the quasi-categories define an exponential ideal in the simplicially enriched category of simplicial sets: if $X$ is a simplicial set and $A$ is a quasi-category, then $A^X$ is a quasi-category. We will deduce this as a corollary of the “relative” version of this result involving a class of maps called isofibrations that we now introduce.

⁶The second statement subsumes the first, but the first is typically used to prove the second.
⁷In a quasi-category, any left and right inverses to a common 1-simplex are homotopic by Lemma 1.1.12. Applying Lemma 1.1.12 it follows that any isomorphism in fact has a single two-sided inverse. In fact, considerably more is true: see Corollary 1.1.16.
1.1.17. Definition (isofibrations between quasi-categories). A simplicial map \( f : A \to B \) between quasi-categories is a isofibration if it lifts against the inner horn inclusions, as displayed below left, and also against the inclusion of either vertex into the free-standing isomorphism \( \mathbb{I} \).

\[
\begin{array}{ccc}
A \times [n] & \longrightarrow & A \\
\downarrow & & \downarrow f \\
\Delta [n] & \longrightarrow & B \\
\end{array}
\quad \begin{array}{ccc}
\mathbb{I} & \longrightarrow & A \\
\downarrow & & \downarrow f \\
\mathbb{I} & \longrightarrow & B \\
\end{array}
\]

To notationally distinguish the isofibrations, we depict them as arrows “\( \Rightarrow \)” with two heads.

By Theorem D.4.19, the isofibrations between quasi-categories can be understood as those maps that admit fillers for all inner horns as well as special outer horns in dimension \( n \geq 1 \), as opposed to only those horns with \( n \geq 2 \) appearing in the statement of Proposition 1.1.14.

1.1.18. Observation.

(i) For any simplicial set \( X \), the unique map \( X \to \ast \) whose codomain is the terminal simplicial set is an isofibration if and only if \( X \) is a quasi-category.

(ii) Any class of maps, such as the isofibrations, that is characterized by a right lifting property is automatically closed under composition, product, pullback, retract, and limits of towers; see Lemma C.2.3.

(iii) Combining (i) and (ii), if \( A \to B \) is an isofibration, and \( B \) is a quasi-category, then so is \( A \).

(iv) The isofibrations generalize the eponymous categorical notion. The nerve of any functor \( f : A \to B \) between categories defines a map of simplicial sets that lifts against the inner horn inclusions. This map then defines an isofibration if and only if given any isomorphism in \( B \) and specified object in \( A \) lifting either its domain or codomain, there exists an isomorphism in \( A \) with that domain or codomain lifting the isomorphism in \( B \).

Much harder to establish is the stability of the class of isofibrations under the formation of “Leibniz\(^8\) exponentials” as displayed in (1.1.20). The proof of this result appears as Proposition D.5.1.

1.1.19. Proposition. If \( i : X \to Y \) is a monomorphism and \( f : A \to B \) is an isofibration, then the induced Leibniz exponential map \( i \lhd f \)

\[
\begin{array}{ccc}
A^Y & \longrightarrow & A^X \\
\downarrow & & \downarrow f^X \\
B^Y & \longrightarrow & B^X \\
\end{array}
\]

is again an isofibration.\(^9\)

1.1.21. Corollary. If \( X \) is a simplicial set and \( A \) is a quasi-category, then \( A^X \) is a quasi-category. Moreover, a 1-simplex in \( A^X \) is an isomorphism if and only if its components at each vertex of \( X \) are isomorphisms in \( A \).

\(^8\)The name alludes to the Leibniz rule in differential calculus, or more specifically to the identification of the domain of the Leibniz product of Lemma D.3.1 with the boundary of the prism; see Remark D.3.2.

\(^9\)Degenerate cases of this result, taking \( X = \emptyset \) or \( B = \ast \), imply that the other six maps in this diagram are also isofibrations; see Exercise 1.1.vii.
Proof. The first statement is a special case of Proposition 1.1.19; see Exercise 1.1.vii. The second statement is proven similarly by arguing with marked simplicial sets. See Corollary D.4.18. □

1.1.22. Definition (equivalences of quasi-categories). A map \( f : A \to B \) between quasi-categories is an equivalence if it extends to the data of a “homotopy equivalence” with the free-living isomorphism \( I \) serving as the interval: that is, if there exist maps \( g : B \to A \) and

\[
\begin{array}{ccc}
A & \xrightarrow{\alpha} & A^I \\
\downarrow{gf} & & \downarrow{ev_1} \\
A & \xrightarrow{} & A
\end{array}
\]

\[
\begin{array}{ccc}
B & \xleftarrow{f g} & B^I \\
\downarrow{ev_0} & & \downarrow{ev_1} \\
B & \xleftarrow{} & B
\end{array}
\]

We write “\( \Rightarrow \)” to decorate equivalences and \( A \cong B \) to indicate the presence of an equivalence \( A \Rightarrow B \).

1.1.23. Remark. If \( f : A \to B \) is an equivalence of quasi-categories equipped with the homotopy equivalence data displayed above, then the functor \( h f : hA \to hB \) is an equivalence of categories, with equivalence inverse \( h g : hB \to hA \) and natural isomorphisms encoded by the composite functors

\[
\begin{array}{ccc}
hA & \xrightarrow{ha} & (hA)^I \\
\downarrow{h f g} & & \downarrow{h g f} \\
hB & \xrightarrow{h g} & (hB)^I
\end{array}
\]

1.1.24. Definition. A map \( f : X \to Y \) between simplicial sets is a trivial fibration if it admits lifts against the boundary inclusions for all simplices

\[
\begin{array}{ccc}
\partial \Delta[n] & \to & X \\
\downarrow & & \downarrow f \\
\Delta[n] & \to & Y
\end{array}
\]

We write “\( \Rightarrow \)” to decorate trivial fibrations.

1.1.26. Remark. The simplex boundary inclusions \( \partial \Delta[n] \hookrightarrow \Delta[n] \) “cellularly generate” the monomorphisms of simplicial sets — see Definition C.2.4 and Lemma C.5.9. Hence the dual of Lemma C.2.3 implies that trivial fibrations lift against any monomorphism between simplicial sets. In particular, applying this to the map \( \emptyset \to Y \), it follows that any trivial fibration \( X \Rightarrow Y \) is a split epimorphism.

The notation “\( \Rightarrow \)” is suggestive: the trivial fibrations between quasi-categories are exactly those maps that are both isofibrations and equivalences. This can be proven by a relatively standard although rather technical argument in simplicial homotopy theory, appearing as Proposition D.5.2.

1.1.27. Proposition. For a map \( f : A \to B \) between quasi-categories the following are equivalent:

(i) \( f \) is a trivial fibration

(ii) \( f \) is both an isofibration and an equivalence

\( \text{Note that } h(\Delta^I) \not\cong (hA)^I \) in general. Objects in the latter are homotopy classes of isomorphisms in \( A \), while objects in the former are homotopy coherent isomorphisms, given by a specified 1-simplex in \( A \), a specified inverse 1-simplex, together with an infinite tower of coherence data indexed by the non-degenerate simplices in \( I \).
(iii) \( f \) is a split fiber homotopy equivalence: an isofibration admitting a section \( s \) that is also an equivalence inverse via a homotopy \( \alpha \) from \( 1_A \) to \( sf \) that composes with \( f \) to the constant homotopy from \( f \) to \( f \).

\[
\begin{array}{ccc}
A + A & \xrightarrow{(id_A, f)} & A \\
\downarrow & & \downarrow \\
A \times \mathbb{I} & \xrightarrow{\alpha} & A & \xrightarrow{f} & B \\
\end{array}
\]

As a class characterized by a right lifting property, the trivial fibrations are also closed under composition, product, pullback, limits of towers, and contain the isomorphisms. The stability of these maps under Leibniz exponentiation is proven in Proposition D.5.1, the same result that proves Proposition 1.1.19.

1.1.28. Proposition. If \( i : X \to Y \) is a monomorphism and \( f : A \to B \) is an isofibration, then if either \( f \) is a trivial fibration or if \( i \) is in the class cellularly generated by the inner horn inclusions and the map \( \mathbb{I} \hookrightarrow \mathbb{I} \) then the induced Leibniz exponential map

\[
A^Y \xrightarrow{i \circ f} B^Y \times_{B^X} A^X
\]

a trivial fibration.

To illustrate the utility of these Leibniz stability results, we give an “internal” or “synthetic” characterization of the Kan complexes.

1.1.29. Lemma. A quasi-category \( A \) is a Kan complex if and only if the map \( A \hookrightarrow A^2 \) induced by the inclusion \( \mathbb{I} \hookrightarrow \mathbb{I} \) is a trivial fibration.

Note that Proposition 1.1.19 implies that \( A \hookrightarrow A^2 \) is an isofibration.

Proof. The lifting property that characterizes trivial fibrations transposes to another lifting property, displayed below-right

\[
\begin{array}{ccc}
\partial \Delta[n] & \hookrightarrow & A^\mathbb{I} \\
\downarrow & & \downarrow \\
\Delta[n] & \hookrightarrow & A^2 \\
\end{array}
\]

\[
\begin{array}{ccc}
\partial \Delta[n] \times_{\partial \Delta[n] \times \mathbb{I}} \Delta[n] \times \mathbb{I} & \hookrightarrow & A \\
\downarrow & & \downarrow \\
\Delta[n] \times \mathbb{I} & \hookrightarrow & \\
\end{array}
\]

that asserts that \( A \) admits extensions along maps formed by taking the Leibniz product—also known as the pushout product—of a simplex boundary inclusion \( \partial \Delta[n] \hookrightarrow \Delta[n] \) with the inclusion \( \mathbb{I} \hookrightarrow \mathbb{I} \).

By Exercise 1.1.v(ii) the inclusion \( \mathbb{I} \hookrightarrow \mathbb{I} \) is a sequential composite of left outer horn inclusions. By Corollary D.3.12, a key step along the way to the proofs of Propositions 1.1.19 and 1.1.28, it follows that the Leibniz product is also a sequential composite of left and inner horn inclusions. If \( A \) is a Kan complex, then the extensions displayed above right exist, and, by transposing, the map \( A^\mathbb{I} \to A^2 \) is a trivial fibration.

Conversely, if \( A^\mathbb{I} \to A^2 \) is a trivial fibration then in particular it is surjective on vertices. Thus every arrow in \( A \) is an isomorphism, and Corollary 1.1.15 tells us that \( A \) must be a Kan complex.

1.1.30. Digression (the Joyal model structure). The category of simplicial sets bears a Quillen model structure, in the sense of Definition C.3.1, whose fibrant objects are exactly the quasi-categories; all
objects are cofibrant. Between fibrant objects, the fibrations, weak equivalences, and trivial fibrations are precisely the classes of isofibrations, equivalences, and trivial fibrations defined above. Proposition 1.1.27 proves that the trivial fibrations are the intersection of the classes of fibrations and weak equivalences. Propositions 1.1.19 and 1.1.28 reflect the fact that the Joyal model structure is a cartesian closed model category, satisfying the additional axioms of Definition C.3.10.

We have declined to elaborate on the Joyal model structure for quasi-categories alluded to in Digression 1.1.30 because the only aspects of it that we will need are those described above. The results enumerated here suffice to show that the category of quasi-categories defines an ∞-cosmos, a concept to which we now turn.

Exercises.

1.1.i. Exercise. Given any cosimplicial object $C : \Delta \to \mathcal{E}$ valued in any category $\mathcal{E}$, there is an associated nerve functor $N_C$ defined by:

$$
\begin{align*}
\mathcal{E} \xrightarrow{N_C} sSet \\
E \xrightarrow{\hom(C^-, E)} sSet
\end{align*}
$$

By construction $n$-simplices in $N_C E$ correspond to maps $C^n \to E$ in $\mathcal{E}$. Show that if $\mathcal{E}$ is cocomplete, then $N_C$ has a left adjoint defined as the left Kan extension of the functor $C$ along the Yoneda embedding $\mathcal{E} \xrightarrow{\mathcal{E}} sSet$. This gives a second proof of Proposition 1.1.11.

1.1.ii. Exercise (Boardman-Vogt [20]). Consider the set of 1-simplices in a quasi-category with initial vertex $a$ and final vertex $b$.

(i) Prove that the relation defined by $f \sim g$ if and only if there exists a 2-simplex with boundary $a \xrightarrow{f} b$ is an equivalence relation.

(ii) Prove that the relation defined by $f \sim g$ if and only if there exists a 2-simplex with boundary $a \xrightarrow{f} b$ is an equivalence relation.

(iii) Prove that the equivalence relations defined by (i) and (ii) are the same. This proves Lemma 1.1.9.

1.1.iii. Exercise. Consider the free category on the reflexive directed graph

$$
\begin{array}{ccc}
A_1 & \xrightarrow{\delta_1} & A_0, \\
\delta_0 \leftarrow & a_0 & \leftarrow \delta_0
\end{array}
$$

underlying a quasi-category $A$.

(i) Consider the relation that identifies a pair of sequences of composable 1-simplices with common source and common target whenever there exists a simplex of $A$ in which the sequences of 1-simplices define two paths from its initial vertex to its final vertex. Prove that this relation is
stable under pre- and post-composition with 1-simplices and conclude that its transitive closure is a **congruence**: an equivalence relation that is closed under pre- and post-composition.\(^{11}\)

(ii) Consider the congruence relation generated by imposing a composition relation \(h = g \circ f\) witnessed by 2-simplices

\[
\begin{array}{ccc}
a_0 & \overset{h}{\longrightarrow} & a_2 \\
& \Bigg\downarrow \ & \\
& g & \Bigg\downarrow \ \\
& \Bigg\downarrow \ & \\
& f & \Bigg\downarrow \ \\
a_0 & \overset{a_1}{\longrightarrow} & a_2 \\
\end{array}
\]

and prove that this coincides with the relation considered in (i).

(iii) In the congruence relations of (i) and (ii), prove that every sequence of composable 1-simplices in \(A\) is equivalent to a single 1-simplex. Conclude that every morphism in the quotient of the free category by this congruence relation is represented by a 1-simplex in \(A\).

(iv) Prove that for any triple of 1-simplices \(f, g, h\) in \(A\), \(h = g \circ f\) in the homotopy category \(\mathbb{h}A\) of Definition 1.1.10 if and only if there exists a 2-simplex with boundary

\[
\begin{array}{ccc}
a_0 & \overset{h}{\longrightarrow} & a_2 \\
& \Bigg\downarrow \ & \\
& g & \Bigg\downarrow \ \\
& \Bigg\downarrow \ & \\
& f & \Bigg\downarrow \ \\
a_0 & \overset{a_1}{\longrightarrow} & a_2 \\
\end{array}
\]

This proves Lemma 1.1.12.

1.1.iv. **EXERCISE.** Show that any quasi-category in which inner horns admit unique fillers is isomorphic to the nerve of its homotopy category.

1.1.v. **EXERCISE.** Let \(\mathbb{I}\) be the nerve of the free-living isomorphism.

(i) Prove that \(\mathbb{I}\) contains exactly two non-degenerate simplices in each dimension.

(ii) Inductively build \(\mathbb{I}\) from \(\mathbb{2}\) by expressing the inclusion \(\mathbb{2} \hookrightarrow \mathbb{I}\) as a sequential composite of pushouts of left outer horn inclusions\(^{12}\) \(\Lambda^0[n] \hookrightarrow \Delta[n]\), one in each dimension starting with \(n = 2\).\(^{13}\)

1.1.vi. **EXERCISE.** Prove the relative version of Corollary 1.1.16: for any isofibration \(p: A \twoheadrightarrow B\) between quasi-categories and any \(f: \mathbb{2} \rightarrow A\) that defines an isomorphism in \(A\) any homotopy coherent isomorphism in \(B\) extending \(pf\) lifts to a homotopy coherent isomorphism in \(A\) extending \(f\).

\[
\begin{array}{ccc}
\mathbb{2} & \overset{f}{\longrightarrow} & A \\
\downarrow & & \downarrow p \\
\mathbb{I} & \longrightarrow & B \\
\end{array}
\]

1.1.vii. **EXERCISE.** Specialize Proposition 1.1.19 to prove the following:

(i) If \(A\) is a quasi-category and \(X\) is a simplicial set then \(A^X\) is a quasi-category.

(ii) If \(A\) is a quasi-category and \(X \hookrightarrow Y\) is a monomorphism then \(A^Y \twoheadrightarrow A^X\) is an isofibration.

\(^{11}\)Given a congruence relation on the hom-sets of a 1-category, the quotient category can be formed by quotienting each hom-set; see [79, §II.8].

\(^{12}\)By the duality described in Definition 1.2.25, the right outer horn inclusions \(\Lambda^1[n] \hookrightarrow \Delta[n]\) can be used instead.

\(^{13}\)This decomposition of the inclusion \(\mathbb{2} \hookrightarrow \mathbb{I}\) reveals which data can always be extended to a homotopy coherent isomorphism: for instance, the 1- and 2-simplices of Definition 1.1.13 together with a single 3-simplex that has these as its outer faces with its inner faces degenerate. Homotopy type theorists refer to this data as a **half adjoint equivalence** [121, §4.2].
If $A \to B$ is an isofibration and $X$ is a simplicial set then $A^X \to B^X$ is an isofibration.

1.1.viii. Exercise. Anticipating Lemma 1.2.20:
(i) Prove that the equivalences defined in Definition 1.1.22 are closed under retracts.
(ii) Prove that the equivalences defined in Definition 1.1.22 satisfy the 2-of-3 property.

1.1.ix. Exercise. Prove that if $f : X \Rightarrow Y$ is a trivial fibration between quasi-categories then the functor $h f : h X \Rightarrow h Y$ is a surjective equivalence of categories.

1.2. $\infty$-Cosmoi

In §1.1, we presented “analytic” proofs of a few of the basic facts about quasi-categories. The category theory of quasi-categories can be developed in a similar style, but we aim instead to develop the “synthetic” theory of infinite-dimensional categories, so that our results will apply to many models at once. To achieve this, our strategy is not to axiomatize what infinite-dimensional categories are, but rather to axiomatize the categorical “universe” in which they live.

The following definition introduces the notion of an $\infty$-cosmos, which abstracts the properties of the category of quasi-categories together with the classes of isofibrations, equivalences, and trivial fibrations introduced in §1.1.14 Firstly, the category of quasi-categories is enriched over the category of simplicial sets — the set of morphisms from $A$ to $B$ coincides with the set of vertices of the simplicial set $B^A$ — and moreover these hom-spaces are all quasi-categories. Secondly, certain limit constructions that can be defined in the underlying unenriched category of quasi-categories satisfy universal properties relative to this simplicial enrichment, with the usual isomorphism of sets extending to an isomorphism of simplicial sets. And finally, the classes of isofibrations, equivalences, and trivial fibrations satisfy properties that are familiar from abstract homotopy theory, forming a category of fibrant objects à la Brown [23] and reviewed in Appendix C. In particular, the use of isofibrations in diagrams guarantees that their strict limits are equivalence invariant, so we can take advantage of up-to-isomorphism universal properties and strict functoriality of these constructions while still working “homotopically.”

As will be explained in Digression 1.2.13, there are a variety of models of infinite-dimensional categories for which the category of “$\infty$-categories,” as we will call them, and “$\infty$-functors” between them is enriched over quasi-categories and admits classes of isofibrations, equivalences, and trivial fibrations satisfying analogous properties. This motivates the following axiomatization:

1.2.1. Definition ($\infty$-cosmoi). An $\infty$-cosmos $\mathcal{K}$ is a category that is enriched over quasi-categories,15 meaning in particular that

- its morphisms $f : A \to B$ define the vertices of a quasi-category denoted $\text{Fun}(A, B)$ and referred to as a functor space

that is also equipped with a specified class of maps that we call isofibrations and denote by $\hookrightarrow$ and satisfies the following two axioms:

(i) (completeness) The quasi-categorically enriched category $\mathcal{K}$ possesses a terminal object, small products, pullbacks of isofibrations, limits of countable towers of isofibrations, and cotensors with all simplicial sets, each of these limit notions satisfying a universal property that is enriched over simplicial sets.16

14Metaphorical allusions aside, our $\infty$-cosmoi resemble the fibrational cosmoi of Street [115].
15This is to say $\mathcal{K}$ is a simplicially enriched category whose hom-spaces are all quasi-categories; this will be unpacked in 1.2.4.
16This will be elaborated upon in 1.2.6.
(ii) (isofibrations) The class of isofibrations contains all isomorphisms and any map whose codo-
main is the terminal object; is closed under composition, product, pullback, forming inverse
limits of towers, and Leibniz cotensors with monomorphisms of simplicial sets; and has the
property that if \( f: A \to B \) is an isofibration and \( X \) is any object then \( \text{Fun}(X, A) \to \text{Fun}(X, B) \)
is an isofibration of quasi-categories.

1.2.2. Definition. In an \( \infty \)-cosmos \( \mathcal{K} \), we define a morphism \( f: A \to B \) to be

- an equivalence if and only if the induced map \( f_*: \text{Fun}(X, A) \to \text{Fun}(X, B) \) on functor spaces is
an equivalence of quasi-categories for all \( X \in \mathcal{K} \), and
- a trivial fibration just when \( f \) is both an isofibration and an equivalence.

These classes are denoted by “\( \Rightarrow \)” and “\( \Rightarrow \Rightarrow \)” respectively.

Put more concisely, one might say that an \( \infty \)-cosmos is a “quasi-categorically enriched category of
fibrant objects.” See Definition C.1.1 and Example C.1.3.

1.2.3. Convention (\( \infty \)-category, as a technical term). Henceforth, we recast \( \infty \)-category as a technical
term to refer to an object in an arbitrary ambient \( \infty \)-cosmos. Similarly, we use the term \( \infty \)-functor—or
more commonly the abbreviation “functor”—to refer to a morphism \( f: A \to B \) in an \( \infty \)-cosmos. This
explains why we refer to the quasi-category \( \text{Fun}(A, B) \) between two \( \infty \)-categories in an \( \infty \)-cosmos as a
“functor space”: its vertices are the (\( \infty \)-)functors from \( A \) to \( B \).

1.2.4. Digression (simplicial categories). A simplicial category \( \mathcal{A} \) is given by categories \( \mathcal{A}_n \), with a
common set of objects and whose arrows are called \( n \)-arrows, that assemble into a diagram \( \Delta^{op} \to \text{Cat} \)
of identity-on-objects functors

\[
\begin{array}{ccccccc}
\vdots & \mathcal{A}_3 & \leftarrow & \mathcal{A}_2 & \leftarrow & \mathcal{A}_1 & \leftarrow & \mathcal{A}_0 \\
\delta_3 & \sigma_2 & \delta_2 & \sigma_1 & \delta_1 & \sigma_0 & \delta_0 \\
\end{array}
\]

(1.2.5)

The data of a simplicial category can equivalently be encoded by a simplicially enriched category
with a set of objects and a simplicial set \( \mathcal{A}(x, y) \) of morphisms between each ordered pair of objects:
an \( n \)-arrow in \( \mathcal{A}_n \) from \( x \) to \( y \) corresponds to an \( n \)-simplex in \( \mathcal{A}(x, y) \); see Exercise 1.2.1. Each endo-
hom-space contains a distinguished identity \( 0 \)-arrow (the degenerate images of which define the
corresponding identity \( n \)-arrows) and composition is required to define a simplicial map

\[
\mathcal{A}(y, z) \times \mathcal{A}(x, y) \to \mathcal{A}(x, z)
\]

the single map encoding the compositions in each of the categories \( \mathcal{A}_n \) and also the functoriality of
the diagram (1.2.5). The composition is required to be associative and unital, in a sense expressed by
the commutative diagrams

\[
\begin{array}{ccc}
\mathcal{A}(y, z) \times \mathcal{A}(x, y) \times \mathcal{A}(w, x) & \to & \mathcal{A}(x, z) \times \mathcal{A}(w, x) \\
\mathcal{A}(y, z) \times \mathcal{A}(w, y) & \to & \mathcal{A}(w, z) \\
\mathcal{A}(x, y) \times \mathcal{A}(x, x) & \to & \mathcal{A}(x, y)
\end{array}
\]

the latter making use of natural isomorphisms \( \mathcal{A}(x, y) \times 1 \cong \mathcal{A}(x, y) \cong 1 \times \mathcal{A}(x, y) \) in the domain
vertex.
On account of the equivalence between these two presentations, the terms “simplicial category” and “simplicially-enriched category” are generally taken to be synonyms. The category $\mathcal{A}_0$ of 0-arrows is the underlying category of the simplicial category $\mathcal{A}$, which forgets the higher dimensional simplicial structure.

In particular, the underlying category $\mathcal{K}_0$ of an $\infty$-cosmos $\mathcal{K}$ is the category whose objects are the $\infty$-categories in $\mathcal{K}$ and whose morphisms are the $\infty$-functors, i.e., the 0-arrows in the functor spaces. In all of the examples to appear below, this recovers the expected category of $\infty$-categories in a particular model and functors between them.

1.2.6. Digression (simplicially enriched limits). Let $\mathcal{A}$ be a simplicial category. The cotensor of an object $A \in \mathcal{A}$ by a simplicial set $U$ is characterized by an isomorphism of simplicial sets

$$\mathcal{A}(X, A^U) \cong \mathcal{A}(X, A)^U$$

natural in $X \in \mathcal{A}$. Assuming such objects exist, the simplicial cotensor defines a bifunctor

$$\text{sSet}^{\text{op}} \times \mathcal{A} \longrightarrow \mathcal{A}$$

$$(U, A) \longmapsto A^U$$

in a unique way making the isomorphism (1.2.7) natural in $U$ and $A$ as well.

The other simplicial limit notions postulated by axiom 1.2.1(i) are conical, which is the term used for ordinary 1-categorical limit shapes that satisfy an enriched analog of the usual universal property; see Definition 3.8. When these limits exist they correspond to the usual limits in the underlying category, but the usual universal property is strengthened. Applying the covariant representable functor $\mathcal{A}(X, -): \mathcal{A}_0 \rightarrow \text{sSet}$ to a limit cone $(\lim_{j \in J} A_j \rightarrow A_j)_{j \in J}$ in $\mathcal{A}_0$ yields a natural comparison map

$$\mathcal{A}(X, \lim_{j \in J} A_j) \rightarrow \lim_{j \in J} \mathcal{A}(X, A_j).$$

(1.2.8)

We say that $\lim_{j \in J} A_j$ defines a simplicially enriched limit if and only if (1.2.8) is an isomorphism of simplicial sets for all $X \in \mathcal{A}$.

Considerably more details on the general theory of enriched categories can be found in [67] and in Appendix A. Enriched limits are the subjects of §A.4 and §A.5.

1.2.9. Preview (flexible weighted limits in $\infty$-cosmoi). The axiom 1.2.1(i) implies that any $\infty$-cosmos $\mathcal{K}$ admits all flexible limits (see Definition 6.2.1 and Proposition 6.3.1), a much larger class of simplicially enriched “weighted” limits that will be introduced in §6.2.

We quickly introduce the three examples of $\infty$-cosmoi that are most easily absorbed, deferring more sophisticated examples to the end of this section. The first of these is the prototypical $\infty$-cosmos. Using the results of Joyal discussed in §1.1 and the classes of isofibrations, equivalences, and trivial fibrations introduced in Definitions 1.1.17, 1.1.22, and 1.1.24:

1.2.10. Proposition (the $\infty$-cosmos of quasi-categories). The full subcategory $\mathcal{QC} \subset \text{sSet}$ of quasi-categories defines an $\infty$-cosmos in which the isofibrations, equivalences, and trivial fibrations coincide with the classes already bearing these names.

¹⁷The phrase “simplicial object in $\text{Cat}$” is reserved for the more general yet less common notion of a diagram $\Delta^{\text{op}} \rightarrow \text{Cat}$ that is not necessarily comprised of identity-on-objects functors.
Proof. The subcategory $\mathbf{QCat} \subseteq \mathbf{sSet}$ inherits its simplicial enrichment from the cartesian closed category of simplicial sets: by Proposition 1.1.19, whenever $A$ and $B$ are quasi-categories, $\text{Fun}(A, B) \equiv B^A$ is again a quasi-category.

The limits postulated in 1.2.1(i) exist in the ambient category of simplicial sets.\footnote{Any category of presheaves is cartesian closed, complete, and cocomplete — a “cosmos” in the sense of Bénabou.} For instance, the defining universal property of the simplicial cotensor (1.2.7) is satisfied by the exponentials of simplicial sets. Moreover, since simplicial sets is a cartesian closed category, each of the conical limits is simplicially enriched in the sense discussed in Digression 1.2.6; the reader is guided through this argument in Exercise 1.2.ii and a general proof appears in Proposition A.5.5.

We now argue that the full subcategory of quasi-categories inherits all these limit notions and at the same time establish the stability of the class of isofibrations under the formation of these limits. In fact, this latter property will help to prove the former. To see this, note that a simplicial set is a quasi-category if and only if the map from it to the point is an isofibration. More generally, if the codomain of any isofibration is a quasi-category then its domain must be as well. So if any of the maps in a limit cone over a diagram of quasi-categories are isofibrations, then it follows that the limit is itself a quasi-category.

Since the class of isofibrations is characterized by a right lifting property, Lemma C.2.3 implies that the isofibrations contains all isomorphism and are closed under composition, product, pullback, and forming inverse limits of towers. In particular, the full subcategory of quasi-categories possesses these limits. This verifies all of the axioms of 1.2.1(i) and 1.2.1(ii) except for the last two: Leibniz closure and closure under exponentiation $(-)^X$. These last closure properties are established in Proposition 1.1.19, and in fact by Exercise 1.1.vii, the former subsumes the latter. This completes the verification of the $\infty$-cosmos axioms.

It remains to check that the classes of equivalences and of trivial fibrations coincide with those defined by 1.1.24 and 1.1.22. By Proposition 1.1.27 the latter coincidence follows from the former, so it remains only to show that the equivalences of 1.1.22 coincide with the representably-defined equivalences: those maps of quasi-categories $f: A \to B$ for which $A^X \to B^X$ is an equivalence of quasi-categories in the sense of Definition 1.1.22. Taking $X = \Delta[0]$, we see immediately that representably-defined equivalences are equivalences, and the converse holds since the exponential $(-)^X$ preserves the data defining a simplicial homotopy.

Two full examples fit into a common paradigm: both arise as full subcategories of the $\infty$-cosmos $\mathbf{QCat}$ and inherit their $\infty$-cosmos structure from this inclusion; see Lemma 6.1.4. But it is also instructive—and ultimately takes less work than went into the proof of Proposition 1.2.10—to describe the resulting $\infty$-cosmos structures directly.

1.2.11. Proposition (the $\infty$-cosmos of categories). The category $\mathbf{Cat}$ of 1-categories defines an $\infty$-cosmos whose isofibrations are the isofibrations: functors satisfying the displayed right lifting property:

\[
\begin{array}{ccc}
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
\| & \to & \| \\
A & \to & B
\end{array}
\]

The equivalences are the equivalences of categories and the trivial fibrations are surjective equivalences: equivalences of categories that are also surjective on objects.
Proof. It is well-known that the 2-category of categories is complete (and in fact also cocomplete) as a \textit{Cat}-enriched category; see Definition A.6.18 or [66]. The categorically enriched category of categories becomes a quasi-categorically enriched category by applying the nerve functor to the hom-categories. It follows formally that these 2-categorical limits become simplicially enriched limits; see §A.7. In particular, as proscribed there and explored in Exercise 1.2.iii, the cotensor of a category \(A\) by a simplicial set \(U\) is defined to be the functor category \(A^{hU}\). This completes the verification of axiom (i).

Since the class of isofibrations is characterized by a right lifting property, Lemma C.2.3 implies that the isofibrations are closed under all of the limit constructions of 1.2.1(ii) except for the last two, and by Exercise 1.1.vii, the Leibniz closure subsumes the closure under exponentiation.

To verify that isofibrations of categories \(f: A \rightarrow B\) are stable under forming Leibniz cotensors with monomorphisms of simplicial sets \(i: U \rightarrow V\), we must solve the lifting problem below-left

\[
\begin{align*}
\begin{array}{ccc}
\mathbb{I} & \xrightarrow{s} & A^{hV} \\
\downarrow & & \downarrow f \\
\mathbb{I} & \xrightarrow{(\beta, \alpha)} & B^{hV} \times_{B^{hU}} A^{hU}
\end{array}
\end{align*}
\]

which transposes to the lifting problem above-right, which we can solve by hand. Here the map \(\beta\) defines a natural isomorphism between \(fs: hV \rightarrow B\) and a second functor. Our task is to lift this to a natural isomorphism \(\gamma\) from \(s\) to another functor that extends the natural isomorphism \(\alpha\) along \(h i: hU \rightarrow hV\). Note this functor \(h i\) need not be an inclusion, but it is injective on objects, which will be enough.

We define the components of \(\gamma\) by cases. If an object \(v \in hV\) is equal to \(i(u)\) for some \(u \in hU\) define \(\gamma_{i(u)} := \alpha_u\); otherwise, use the fact that \(f\) is an isofibration to define \(\gamma_v\) to be any lift of the isomorphism \(\beta_v\) to an isomorphism in \(A\) with domain \(s(v)\). The data of the map \(\gamma: hV \times \mathbb{I} \rightarrow A\) also entails the specification of the functor \(hV \rightarrow A\) that is the codomain of the natural transformation \(\gamma\). On objects, this functor is given by \(v \mapsto \text{cod}(\gamma_v)\). On morphisms, this functor defined in the unique way that makes \(\gamma\) into a natural transformation:

\[
(k: v \rightarrow v') \mapsto \gamma_{v'} \circ s(k) \circ \gamma_{v}^{-1}.
\]

This completes the proof that \textit{Cat} defines an \(\infty\)-cosmos. We leave the characterization of the classes of equivalences and trivial fibrations to the reader. \(\square\)

1.2.12. Proposition (the \(\infty\)-cosmos of Kan complexes). The category \textit{Kan} of Kan complexes defines an \(\infty\)-cosmos whose isofibrations are the \textbf{Kan fibrations}: maps that lift against all horn inclusions \(\Lambda^k[n] \rightarrow \Delta[n]\) for \(n \geq 1\) and \(0 \leq k \leq n\).

Here the proof will proceed along the lines of Lemma 6.1.4. We will show that the subcategory of Kan complexes inherits an \(\infty\)-cosmos structure by restricting structure from the \(\infty\)-cosmos of quasi-categories.

Proof. By Proposition 1.1.14, an isofibration between Kan complexes is a Kan fibration. Conversely, since the homotopy coherent isomorphism \(\mathbb{I}\) can be built from the point \(\mathbb{I}\) by attaching fillers to a sequence of outer horns, all Kan fibrations define isofibrations. This shows that between Kan fibrations, the classes of isofibrations and Kan fibrations coincide. So to show that the category of Kan complexes inherits an \(\infty\)-cosmos structure by restriction from the \(\infty\)-cosmos of quasi-categories, we need only
verify that the full subcategory $\text{Kan} \hookrightarrow \text{QCat}$ is closed under all of the limit constructions of axiom 1.2.1(i). For the conical limits, the argument mirrors the one given in the proof of Proposition 1.2.10, while the closure under cotensors is a consequence of Corollary D.3.12, which says that the Kan complexes also define an exponential ideal in the category of simplicial sets. The remaining axiom 1.2.1(ii) is inherited from the analogous properties established for quasi-categories in Proposition 1.2.10.

We mention a common source of $\infty$-cosmoi found in nature to help ground the intuition for readers familiar with Quillen's model categories, a popular framework for "abstract homotopy theory," but reassure newcomers that model categories are not needed outside of Appendix E where these results are proven.

1.2.13. DIGRESSION (a source of $\infty$-cosmoi in nature). As explained in §E.1, certain easily described properties of a model category imply that the full subcategory of fibrant objects defines an $\infty$-cosmos whose isofibrations, equivalences, and trivial fibrations are the fibrations, weak equivalences, and trivial fibrations between fibrant objects. Namely, any model category that is enriched as such over the Joyal model structure on simplicial sets and with the property that all fibrant objects are cofibrant has this property; see Proposition E.1.1. This model-categorical enrichment over quasi-categories can be defined when the model category is cartesian closed and equipped with a right Quillen adjoint to the Joyal model structure on simplicial sets whose left adjoint preserves finite products; see Proposition E.1.3. In this case, the right adjoint becomes the underlying quasi-category functor (see Proposition 1.3.3(ii)) and the $\infty$-cosmos so-produced will then be cartesian closed (see Definition 1.2.23). The $\infty$-cosmoi listed in Example 1.2.24 all arise in this way.

The following results are consequences of the axioms of Definition 1.2.1. The first of these results tells us that the trivial fibrations enjoy all of the same stability properties satisfied by the isofibrations.

1.2.14. LEMMA (stability of trivial fibrations). The trivial fibrations in an $\infty$-cosmos define a subcategory containing the isomorphisms and are stable under product, pullback, and forming inverse limits of towers. Moreover, the Leibniz cotensors of any trivial fibration with a monomorphism of simplicial sets is a trivial fibration as is the Leibniz cotensor of an isofibration with a map in the class cellularly generated by the inner horn inclusions and the map $\mathbf{1} \hookrightarrow \mathbf{I}$, and if $E \Rightarrow B$ is a trivial fibration then so is $\text{Fun}(X, E) \Rightarrow \text{Fun}(X, B)$.

Proof. We prove these statements in the reverse order. By axiom 1.2.1(ii) and the definition of the trivial fibrations in an $\infty$-cosmos, we know that if $E \Rightarrow B$ is a trivial fibration then is $\text{Fun}(X, E) \Rightarrow \text{Fun}(X, B)$ is both an isofibration and an equivalence, and hence by Proposition 1.1.27 a trivial fibration. For stability under the remaining constructions, we know in each case that the maps in question are isofibrations in the $\infty$-cosmos; it remains to show only that the maps are also equivalences. The equivalences in an $\infty$-cosmos are defined to be the maps that $\text{Fun}(X, -)$ carries to equivalences of quasi-categories, so it suffices to verify that trivial fibrations of quasi-categories satisfy the corresponding stability properties. This is established in Proposition 1.1.28 for the Leibniz stability properties and by the fact that that class is characterized by a right lifting property for the remaining ones.

Additionally, every trivial fibration is “split” by a section.
1.2.15. Lemma (trivial fibrations split). Every trivial fibration admits a section

\[
\begin{array}{c}
E \\
\downarrow^p \\
B = B
\end{array}
\xrightarrow{\gamma} \begin{array}{c}
\begin{array}{c}
E + E \\
\downarrow^p \\
E \times \mathbb{I}
\end{array}
\xrightarrow{(id_E, sp)} \begin{array}{c}
E \\
\downarrow^p \\
E \times \mathbb{I}
\end{array}
\xrightarrow{\pi} \begin{array}{c}
E \\
\downarrow^p \\
B
\end{array}
\end{array}
\]

The map \( \gamma \) defines a split fiber homotopy equivalence

\[
\begin{array}{c}
E + E \\
\downarrow^p \\
E \times \mathbb{I}
\end{array}
\xrightarrow{\gamma} \begin{array}{c}
E \\
\downarrow^p \\
E \times \mathbb{I}
\end{array}
\xrightarrow{\pi} \begin{array}{c}
E \\
\downarrow^p \\
B
\end{array}
\]

Proof. If \( p : E \Rightarrow B \) is a trivial fibration, then by the final stability property of Lemma 1.2.14, so is \( p_* : \text{Fun}(X, E) \Rightarrow \text{Fun}(X, B) \) for any \( \infty \)-category \( X \). By Definition 1.1.24, we may solve the lifting problem below-left

\[
\begin{array}{c}
\emptyset = \partial \Delta[0] \\
\downarrow^s \\
\mathbb{I} = \Delta[0]
\end{array}
\xrightarrow{id_B} \begin{array}{c}
\text{Fun}(B, E) \\
\downarrow^{p_*} \\
\text{Fun}(B, B)
\end{array}
\]

\[
\begin{array}{c}
\mathbb{I} + \mathbb{I} \\
\downarrow^\alpha \\
\mathbb{I}
\end{array}
\xrightarrow{(id_{\mathbb{I}}, sp)} \begin{array}{c}
\text{Fun}(E, E) \\
\downarrow^{p_*} \\
\text{Fun}(E, B)
\end{array}
\]

to find a map \( s : B \to E \) so that \( ps = id_B \), and then solve the lifting problem above-right to construct the desired fibered homotopy. \( \Box \)

A classical construction in abstract homotopy theory proves the following:

1.2.16. Lemma (Brown factorization lemma). Any functor \( f : A \to B \) in an \( \infty \)-cosmos may be factored as an equivalence followed by an isofibration, where this equivalence is constructed as a section of a trivial fibration.

\[
\begin{array}{c}
A \\
\downarrow^f \\
B
\end{array}
\xrightarrow{Pf} \begin{array}{c}
\begin{array}{c}
Pf \downarrow^q \\
A
\end{array}
\xrightarrow{id_A} \begin{array}{c}
\begin{array}{c}
Pf \downarrow^q \\
A
\end{array}
\xrightarrow{id_A} \begin{array}{c}
B
\end{array}
\end{array}
\end{array}
\]

Proof. The displayed factorization is constructed by the pullback of an isofibration formed by the simplicial cotensor of the inclusion \( \mathbb{I} + \mathbb{I} \hookrightarrow \mathbb{I} \) into the \( \infty \)-category \( B \).

\[
\begin{array}{c}
A \\
\downarrow^s \\
A \times B \\
\downarrow^{f \times B}
\end{array}
\xrightarrow{(q, p)} \begin{array}{c}
(Pf) \downarrow^j \\
B
\end{array}
\xrightarrow{B} \begin{array}{c}
B
\end{array}
\]

Note the map \( q \) is a pullback of the trivial fibration \( ev_0 : B^\mathbb{I} \Rightarrow B \) and is hence a trivial fibration. Its section \( s \), constructed by applying the universal property of the pullback to the displayed cone with summit \( A \), is thus an equivalence. \( \Box \)
By a Yoneda-style argument, the “homotopy equivalence” characterization of the equivalences in the ∞-cosmos of quasi-categories of Definition 1.1.22 extends to an analogous characterization of the equivalences in any ∞-cosmos:

1.2.18. Lemma (equivalences are homotopy equivalences). A map \( f : A \to B \) between ∞-categories in an ∞-cosmos \( \mathcal{K} \) is an equivalence if and only if it extends to the data of a “homotopy equivalence” with the free-living isomorphism \( \mathbb{I} \) serving as the interval: that is, if there exist maps \( g : B \to A \) and

\[
\begin{align*}
A & \xrightarrow{\alpha} A^\mathbb{I} \xleftarrow{gf} A \\
\downarrow^{ev_0} & \quad \downarrow^{ev_1} \\
B & \xrightarrow{\beta} B^\mathbb{I} \xleftarrow{fg} B
\end{align*}
\]

\quad (1.2.19)

in the ∞-cosmos.

Proof. By hypothesis, if \( f : A \to B \) defines an equivalence in the ∞-cosmos \( \mathcal{K} \) then the induced map on post-composition \( f_* : \text{Fun}(B, A) \to \text{Fun}(B, B) \) is an equivalence of quasi-categories in the sense of Definition 1.1.22. Evaluating the inverse equivalence \( \tilde{g} : \text{Fun}(B, B) \Rightarrow \text{Fun}(B, A) \) and homotopy \( \tilde{\beta} : \text{Fun}(B, B) \to \text{Fun}(B, B)^\mathbb{I} \) at the 0-arrow \( 1_B \in \text{Fun}(B, B) \), we obtain a 0-arrow \( g : B \to A \) together with an isomorphism \( \beta : \mathbb{I} \Rightarrow \text{Fun}(B, B) \) from the composite \( fg \) to \( 1_B \). By the defining universal property of the cotensor (1.2.7), this isomorphism internalizes to define the map \( \beta : B \to B^\mathbb{I} \) in \( \mathcal{K} \) displayed on the right of (1.2.19).

Now the hypothesis that \( f \) is an equivalence also provides an equivalence of quasi-categories \( f_* : \text{Fun}(A, A) \Rightarrow \text{Fun}(A, B) \), and the map \( \beta f : A \to B^\mathbb{I} \) represents an isomorphism in \( \text{Fun}(A, B) \) from \( fgf \) to \( f \). Since \( f_* \) is an equivalence, we conclude from Remark 1.1.23 that \( 1_A \) and \( gf \) are isomorphic in the quasi-category \( \text{Fun}(A, A) \): explicitly, such an isomorphism may be defined by applying the inverse equivalence \( \tilde{h} : \text{Fun}(A, B) \Rightarrow \text{Fun}(A, A) \) and composing with the components at \( 1_A, g f \in \text{Fun}(A, A) \) of the isomorphism \( \tilde{\alpha} : \text{Fun}(A, A) \to \text{Fun}(A, A)^\mathbb{I} \) from \( 1_{\text{Fun}(A, A)} \) to \( \tilde{h} f \). Now by Corollary 1.1.16 this isomorphism is represented by a map \( \mathbb{I} \to \text{Fun}(A, A) \) from \( 1_A \) to \( g f \), which internalizes to a map \( \alpha : A \to A^\mathbb{I} \) in \( \mathcal{K} \) displayed on the left of (1.2.19).

The converse is easy: the simplicial cotensor construction commutes with \( \text{Fun}(X, -) \), so a homotopy equivalence (1.2.19) induces a homotopy equivalences of quasi-categories as in Definition 1.1.22. □

1.2.20. Lemma. The class of equivalences in an ∞-cosmos are closed under retracts and satisfy the 2-of-3 property: given a composable pair of functors and their composite, if any two of these are equivalences so is the third.

For the reader who solved Exercise 1.1.viii, demonstrating the equivalences between quasi-categories are closed under retracts and satisfy the 2-of-3 property, Lemma 1.2.20 follows easily from the representable definition of equivalences and functoriality. But for sake of completeness, we give an alternate proof of the general cosmological result that makes use of Lemma 1.2.18 and subsumes Exercise 1.1.viii.
PROOF. Let \( f : A \cong B \) be an equivalence equipped with the data of (1.2.19) and consider a retract diagram

\[
\begin{align*}
C & \xrightarrow{u} A \xrightarrow{v} C \\
& \downarrow h \\
D & \xrightarrow{s} B \xrightarrow{t} D
\end{align*}
\]

By Lemma 1.2.18, to prove that \( h : C \to D \) is an equivalence, it suffices to construct the data of an inverse homotopy equivalence. To that end define \( k : D \to C \) to be the composite \( v \circ g \circ s \) and then observe from the commutative diagrams

\[
\begin{align*}
C & \xrightarrow{u} A \xrightarrow{\alpha} A^\perp \xrightarrow{v^\perp} C^\perp \\
& \downarrow \downarrow h \\
D & \xrightarrow{s} B \xrightarrow{g} A \xrightarrow{v} C
\end{align*}
\]

\[
\begin{align*}
A & \xrightarrow{f} B \xrightarrow{g} A \\
& \downarrow k \\
B & \xrightarrow{\beta} B^\perp \xrightarrow{t^\perp} D^\perp
\end{align*}
\]

that \( v^\perp \alpha u : C \to C^\perp \) and \( t^\perp \beta s : D \to D^\perp \) define the required “homotopies.”

Via Lemma 1.2.18, the 2-of-3 property for equivalences follows from the fact that the set of (homotopy coherent) isomorphisms in a quasi-category is closed under composition. Homotopy coherent isomorphisms in a quasi-category represent isomorphisms in the homotopy category. The composite of a pair of isomorphisms in the homotopy category is then an isomorphism, which by Corollary 1.1.16 can be lifted to a representing homotopy coherent isomorphism.¹⁹ We will apply this to the homotopy coherent isomorphisms in the functor spaces of an \( \infty \)-cosmos that form part of the data of an equivalence of \( \infty \)-categories.

To prove that equivalences are closed under composition, consider a composable pair of equivalences with their inverse equivalences

\[
\begin{align*}
A & \xrightarrow{f} B \xleftarrow{g} C \\
& \xleftarrow{k} \xrightarrow{h}
\end{align*}
\]

The homotopies of Lemma 1.2.18 define isomorphisms \( \alpha : \text{id}_A \cong kf \in \text{Fun}(A, A) \) and \( \gamma : \text{id}_B \cong hg \in \text{Fun}(B, B) \), the latter of which whiskers to define \( k \gamma f : kf \cong khg f \in \text{Fun}(B, B) \). Composing these, we obtain an isomorphism \( \text{id}_A \cong khg f \in \text{Fun}(A, A) \) defining one of the homotopies that witnesses that \( k h \) defines an equivalence inverse of \( g f \). The construction of the other homotopy is dual.

¹⁹In fact, by Example D.4.23, homotopy coherent isomorphisms can be composed directly, but we do not need this here.
To prove that the equivalences are closed under right cancelation, consider a diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B & \xrightarrow{g} & C \\
\downarrow{k} & & \downarrow{\sim} & & \downarrow{\sim} \\
& A & \xleftarrow{\sim} & B & \xrightarrow{\sim} & C
\end{array}
\]

with \(k\) an inverse equivalence to \(f\) and \(\ell\) and inverse equivalence to \(gf\). We will demonstrate that \(f\ell\) defines an inverse equivalence to \(g\). One of the required homotopies \(\text{id}_C \equiv gf\ell\) is given already. The other is obtained by composing three isomorphisms in \(\text{Fun}(B,B)\)

\[
\begin{array}{c}
\text{id}_B \xrightarrow{\beta^{-1}} f k \xrightarrow{f \delta k} f \ell g f k \xrightarrow{f \ell g \beta} f \ell g.
\end{array}
\]

The proof of stability of equivalence under left cancelation is dual. \(\square\)

1.2.21. REMARK (equivalences satisfy the 2-of-6 property). In fact the class of equivalences in any \(\infty\)-cosmos satisfy the stronger **2-of-6 property**: for any composable triple of functors

\[
\begin{array}{ccc}
& & B \\
& & \downarrow{h} \\
& A & \xrightarrow{f} & C & \xleftarrow{g} & D \\
& \downarrow{gf} & & \downarrow{h} & & \downarrow{hg} \\
& & & & \end{array}
\]

if \(gf\) and \(hg\) are equivalences then \(f, g, h,\) and \(hgf\) are too. The proof uses Lemma 1.2.20 together with the observation that in the case where \(f: A \to B\) is an equivalence, the map \(p\) of (1.2.17) is also a trivial fibration, and in particular has a section by Lemma 1.2.15. Combining these facts, a result of Blumberg and Mandell [19, 6.4] reproduced in Proposition C.1.8 applies to prove that the equivalences have the 2-of-6 property. See Corollary C.1.9.

One of the key advantages of the \(\infty\)-cosmological approach to abstract category theory is that there are a myriad varieties of “fibered” \(\infty\)-cosmoi that can be built from a given \(\infty\)-cosmos, which means that any theorem proven in this axiomatic framework specializes and generalizes to those contexts. The most basic of these derived \(\infty\)-cosmoi is the \(\infty\)-cosmos of isofibrations over a fixed base, which we introduce now. Other examples of \(\infty\)-cosmoi will be introduced in Chapter 6, once we have developed a greater facility with the simplicial limits of axiom 1.2.1(i).

1.2.22. PROPOSITION (sliced \(\infty\)-cosmoi). For any \(\infty\)-cosmos \(\mathcal{K}\) and any \(\infty\)-category \(B \in \mathcal{K}\) there is an \(\infty\)-cosmos \(\mathcal{K}_B\) of isofibrations over \(B\) whose

(i) objects are isofibrations \(p: E \to B\) with codomain \(B\)

(ii) functor spaces, say from \(p: E \to B\) to \(q: F \to B\), are defined by pullback

\[
\begin{array}{ccc}
\text{Fun}_B(p: E \to B, q: F \to B) & \longrightarrow & \text{Fun}(E,F) \\
\downarrow{\Delta} & & \downarrow{q_*} \\
\Pi & \xrightarrow{p} & \text{Fun}(E,B)
\end{array}
\]

and abbreviated to \(\text{Fun}_B(E,F)\) when the specified isofibrations are clear from context.

24
(iii) isofibrations are commutative triangles of isofibrations over $B$

$$
\begin{array}{c}
E \\ r \\ \downarrow p \\
B \\
\end{array} \quad \begin{array}{c}
F \\ \downarrow q \\
\end{array}
$$

(iv) terminal object is $1: B \to B$ and products are defined by the pullback along the diagonal

$$
\times B_i E_i \longrightarrow \prod_i E_i \\
\downarrow \quad \downarrow \prod_i p_i

\begin{array}{c}
B \\
\Delta \\
\end{array} \longrightarrow \prod_i B
$$

(v) pullbacks and limits of towers of isofibrations are created by the forgetful functor $\mathcal{K}_B \to \mathcal{K}$

(vi) simplicial cotensors $p: E \to B$ by $U \in \mathcal{S}et$ are constructed by the pullback

$$
\begin{array}{c}
U \circlearrowleft_B p \\
\downarrow \quad \downarrow \quad \downarrow p^U
\end{array} \longrightarrow E^U \\
\begin{array}{c}
B \\
\Delta \\
\end{array} \longrightarrow B^U
$$

(vii) and in which a map over $B$

$$
\begin{array}{c}
E \\ f \\ \downarrow p \\
B \\
\end{array} \longrightarrow \begin{array}{c}
F \\ \downarrow q \\
\end{array}
$$

is an equivalence in the $\infty$-cosmos $\mathcal{K}_B$ if and only if $f$ is an equivalence in $\mathcal{K}$.

**Proof.** Note first that the functor spaces are quasi-categories since axiom 1.2.1(ii) asserts that for any isofibration $q: F \to B$ in $\mathcal{K}$ the map $q_*: \text{Fun}(E, F) \to \text{Fun}(E, B)$ is an isofibration of quasi-categories. Other parts of this axiom imply that that each of the limit constructions—such as the products and cotensors constructed in (iv) and (vi)—define isofibrations over $B$. The closure properties of the isofibrations in $\mathcal{K}_B$ follow from the corresponding ones in $\mathcal{K}$. The most complicated of these is the Leibniz cotensor stability of the isofibrations in $\mathcal{K}_B$, which follows from the corresponding property in $\mathcal{K}$, since for a monomorphism of simplicial sets $i: X \hookrightarrow Y$ and an isofibration $r$ over $B$ as in (iii) above, the map $i \circlearrowleft_B r$ is constructed by pulling back $i \circlearrowleft r$ along $\Delta: B \to B^Y$.

The fact that the above constructions define simplicially enriched limits in a simplicially enriched slice category are standard from enriched category theory. It remains only to verify that the equivalences in the $\infty$-cosmos of isofibrations are created by the forgetful functor $\mathcal{K}_B \to \mathcal{K}$. Suppose first that the map $f$ displayed in (vii) defines an equivalence in $\mathcal{K}$. Then for any isofibration $s: A \to B$ the induced map on functor spaces in $\mathcal{K}_B$ is defined by the pullback:
Since \( f \) is an equivalence in \( \mathcal{K} \), the map \( f_* : \text{Fun}(A, E) \to \text{Fun}(A, F) \) is an equivalence, and so it follows that the induced map on fibers over \( s \) is an equivalence as well. This can be verified either by appealing to Lemmas 1.2.14 and 1.2.16 and using standard techniques from simplicial homotopy theory—as done in Lemma C.1.11—or by appealing to Lemma 1.2.18 and using the fact that pullback along \( s \) defines a simplicial functor.

For the converse implication, we appeal to Lemma 1.2.18. If \( f : E \to F \) is an equivalence in \( \mathcal{K}_{/B} \) then it admits a homotopy inverse in \( \mathcal{K}_{/B} \). The inverse equivalence \( g : F \to E \) also defines an inverse equivalence in \( \mathcal{K} \) and the required simplicial homotopies in \( \mathcal{K} \) are defined by composing with the top horizontal leg of the pullback defining the cotensor in \( \mathcal{K}_{/B} \). □

As mentioned in Digression 1.2.13, many of the \( \infty \)-cosmoi we encounter “in the wild” satisfy an additional axiom. Note, however, that this axiom is not inherited by the sliced \( \infty \)-cosmoi of Proposition 1.2.22, which is one of the reasons it was not included in Definition 1.2.1.

1.2.23. Definition (cartesian closed \( \infty \)-cosmoi). An \( \infty \)-cosmos \( \mathcal{K} \) is cartesian closed if the product bifunctor \( \times : \mathcal{K} \times \mathcal{K} \to \mathcal{K} \) extends to a simplicially enriched two-variable adjunction

\[
\text{Fun}(A \times B, C) \cong \text{Fun}(A, C^B) \cong \text{Fun}(B, C^A)
\]

in which the right adjoints \((\cdot)^A : \mathcal{K} \to \mathcal{K}\) preserve the class of isofibrations for all \( A \in \mathcal{K} \).

For instance, the \( \infty \)-cosmos of quasi-categories is cartesian closed, with the exponentials defined as (special cases of) simplicial cotensors. This is one of the reasons that we use the same notation for cotensor and for exponential.²⁰ Note in this case the functor spaces and the exponentials coincide. The same is true for the cartesian closed \( \infty \)-cosmoi of categories and of Kan complexes; see Exercise 1.2.iii. In general, the functor space from \( A \) to \( B \) is the “underlying quasi-category” of the exponential \( B^A \) whenever it exists; see Remark 1.3.8.

1.2.24. Example (\( \infty \)-cosmoi of (\( \infty, 1 \))-categories; §E.2). The following models of (\( \infty, 1 \))-categories define cartesian closed \( \infty \)-cosmoi:

(i) Rezk’s complete Segal spaces define the objects of an \( \infty \)-cosmos \( \mathcal{CSS} \), in which the isofibrations, equivalences, and trivial fibrations are the corresponding classes of the model structure of [95].²¹

(ii) The Segal categories defined by Dwyer, Kan, and Smith [37] and developed by Hirschowitz and Simpson [53] define the objects of an \( \infty \)-cosmos \( \mathcal{Segal} \), in which the isofibrations, equivalences and trivial fibrations are the corresponding classes of the model structure of [87] and [11].²²

²⁰ Other reasons for this convenient notational conflation will be explained in §2.3 and in Proposition 10.3.5.

²¹ Warning: the model category of complete Segal spaces is enriched over simplicial sets in two distinct “directions” — one enrichment makes the simplicial set of maps between two complete Segal spaces into a Kan complex that probes the “spacial” structure while another enrichment makes the simplicial set of maps into a quasi-category that probes the “categorical” structure [62]. It is this latter enrichment that we want.

²² Here we reserve the term “Segal category” for those simplicial objects with a discrete set of objects that are Reedy fibrant and satisfy the Segal condition. The traditional definition does not include the Reedy fibrancy condition because it is not satisfied by the simplicial object defined as the nerve of a Kan complex enriched category. Since Kan complex enriched categories are not among our preferred models of (\( \infty, 1 \))-categories this does not bother us.
(iii) The 1-complicial sets of [125], equivalently the “naturally marked quasi-categories” of [74], define the objects of an ∞-cosmos 1-Comp in which the isofibrations, equivalences and trivial fibrations are the corresponding classes of the model structure from either of these sources.

In §E.3, we prove that certain models of (∞,n)-categories or even (∞,∞)-categories define ∞-cosmoi: these including n-quasi-categories, Θ_n-spaces, iterated complete Segal spaces, and n-complicial sets, among others.

1.2.25. Definition (co-dual ∞-cosmoi). There is an identity-on-objects functor (−): Δ → Δ that reverses the ordering of the elements in each ordinal [n] ∈ Δ. In the notation of 1.1.1, the functor (−) sends a face map δ^i: [n−1] ↷ [n] to the face map δ^[n−i]: [n−1] ↷ [n] and sends the degeneracy map σ^i: [n+1] ↷ [n] to the degeneracy map σ^[n−i]: [n+1] ↷ [n]. Precomposition with this involutive automorphism induces an involution (−)op: sSet → sSet that sends a simplicial set X to its opposite simplicial set X^op, with the orientation of the vertices in each simplex reversed. This construction preserves all conical limits and colimits and induces an isomorphism (Y^op)^op ≅ (Y^op)X^op on exponentials.

For any ∞-cosmos 𝒦, there is a dual ∞-cosmos 𝒦^co with the same objects but with functor spaces defined by:

\[ \text{Fun}_{\mathcal{K}^{co}}(A, B) := \text{Fun}_{\mathcal{K}}(A, B)^{op}. \]

The isofibrations, equivalences, and trivial fibrations in 𝒦^co coincide with those of 𝒦.

Conical limits in 𝒦^co coincide with those in 𝒦, while the cotensor of A ∈ 𝒦 with U ∈ sSet is defined to be A^U^op.

A 2-categorical justification for this notation is given in Exercise 1.4.iii.

1.2.26. Definition (discrete ∞-categories). An ∞-category E in an ∞-cosmos 𝒦 is discrete just when for all X ∈ 𝒦 the functor space Fun(X, E) is a Kan complex.

In the ∞-cosmos of quasi-categories, the discrete ∞-categories are exactly the Kan complexes. Similarly, in the ∞-cosmoi of Example 1.2.24 whose ∞-categories are (∞,1)-categories in some model, the discrete ∞-categories are the ∞-groupoids. These examples suggest that “discrete ∞-categories” might also be called “groupoidal ∞-categories.” Importantly for what follows, the discrete ∞-categories can be characterized “internally” to the ∞-cosmos as follows:

1.2.27. Lemma. An ∞-category A is discrete if and only if \( A^I \rightarrow A^2 \) is a trivial fibration.

Proof. By Definition 1.2.2, the isofibration \( A^I \rightarrow A^2 \) is a trivial fibration if and only if for all ∞-categories \( X \) the induced map on functor spaces

\[ \text{Fun}(X, A^I) \longrightarrow \text{Fun}(X, A^2) \]

\[ \text{Fun}(X, A)^I \longrightarrow \text{Fun}(X, A)^2 \]

is a trivial fibration of quasi-categories. Via the universal property of the simplicial cotensor, Lemma 1.1.29 tells us that this map is a trivial fibration if and only if \( \text{Fun}(X, A) \) is a Kan complex. □

We leave it to the reader to show that the discrete ∞-categories in any ∞-cosmos assemble into an ∞-cosmos 𝒦^co. A proof appears in Proposition 6.1.6 where general techniques for discussing new ∞-cosmoi from given ones are discussed.
Exercises.

1.2.i. Exercise. Prove that the following are equivalent:

(i) a simplicial category, as in 1.2.4,
(ii) a category enriched over simplicial sets.

1.2.ii. Exercise. Elaborate on the proof of Proposition 1.2.10 by proving that the simplicially enriched category $\mathcal{Q}Cat$ admits conical products satisfying the universal property of Digression 1.2.6. That is:

(i) Define the cartesian product $A \times B$ and the projection maps $\pi_A : A \times B \to A$ and $\pi_B : A \times B \to B$ for a pair of quasi-categories $A$ and $B$ and prove that this data satisfies the usual (unenriched) universal property.

(ii) Given another quasi-category $X$, use (i) and the Yoneda lemma to show that the projection maps induce an isomorphism of quasi-categories $$(A \times B) \times X \cong A \times X \times B \times X.$$ 

(iii) Explain how this relates to the universal property of Digression 1.2.6.

(iv) Express the usual 1-categorical universal property of (i) as the “0-dimensional aspect” of the universal property of (ii).

1.2.iii. Exercise. To complete the proof that categories inherit a cartesian closed $\infty$-cosmos structure from quasi-categories via the nerve embedding $\text{Cat} \hookrightarrow \mathcal{Q}Cat$:

(i) Show that the homotopy category functor $h: s\text{Set} \to \text{Cat}$ of Definition 1.1.10 preserves finite products. For later use, show also that the restricted homotopy category functor $h: \mathcal{Q}Cat \to \text{Cat}$ preserves all products.

(ii) Conclude, by adjunction, that if $A$ and $B$ are categories then the functor space between their nerves is isomorphic to the nerve of the functor category $B^A$. This proves that the inclusion $\text{Cat} \hookrightarrow \mathcal{Q}Cat$ preserves exponentials.

(iii) Show, again by adjunction, that if $A$ is a category and $U$ is a simplicial set that the nerve of the functor category $A^{hU}$ is isomorphic to the simplicial cotensor of the nerve of $A$ with $U$. This proves that the inclusion $\text{Cat} \hookrightarrow \mathcal{Q}Cat$ preserves simplicial cotensors.

1.2.iv. Exercise. Prove that any object in an $\infty$-cosmos has a path object

constructed by cotensoring with the free-living isomorphism.

1.2.v. Exercise. Show that if $\mathcal{K}$ is a cartesian closed $\infty$-cosmos then $\mathcal{K}^\infty$ is as well.

1.2.vi. Exercise (Proposition 6.1.6). Use Proposition 1.2.12 to show that the discrete $\infty$-categories in any $\infty$-cosmos define an $\infty$-cosmos whose functor spaces are all Kan complexes.

1.3. Cosmological Functors

Certain “right adjoint type” constructions define maps between $\infty$-cosmoi that preserve all of the structures axiomatized in Definition 1.2.1. The simple observation that such constructions define cosmological functors between $\infty$-cosmoi will streamline many proofs.
1.3.1. Definition (cosmological functor). A **cosmological functor** is a simplicial functor\(^\text{13}\) \(F: \mathcal{K} \to \mathcal{L}\) between \(\infty\)-cosmoi that preserves the specified classes of isofibrations and all of the simplicial limits enumerated in 1.2.1(i).

In general, cosmological functors preserve any \(\infty\)-categorical notion that can be characterized internally to the \(\infty\)-cosmos — for instance, as additional structure that can be given to a certain map — as opposed to externally — for instance, in a statement that involves a universal quantifier. For example, the equivalences in an \(\infty\)-cosmos are characterized externally in Definition 1.2.2, which might lead one to suspect that a non-surjective cosmological functor could fail to preserve them. However, Lemma 1.2.18 characterizes equivalences in terms of the presence of structures definable internally to an \(\infty\)-cosmos, so as a result:

1.3.2. Lemma. Any cosmological functor also preserves the equivalences and the trivial fibrations.

Proof. By Lemma 1.2.18 the equivalences in an \(\infty\)-cosmos coincide with the homotopy equivalences defined relative to cotensoring with the free-living isomorphism. Since a cosmological functor preserves simplicial cotensors, it preserves the data displayed in (1.2.19) and hence carries equivalences to equivalences. The statement about trivial fibrations follows.

Similarly, arguing from Definition 1.2.26 it would not be clear whether cosmological functors preserve discrete \(\infty\)-categories, but using the internal characterization of Lemma 1.2.27 — an \(\infty\)-category \(A\) is discrete if and only if \(A^1 \Rightarrow A^2\) is a trivial fibration — this follows easily: cosmological functors preserve simplicial cotensors and trivial fibrations.

We now demonstrate that cosmological functors are abundant:

1.3.3. Proposition.

(i) For any \(\infty\)-category \(A\) in an \(\infty\)-cosmos \(\mathcal{K}\), \(\text{Fun}(A, -): \mathcal{K} \to \mathcal{QCat}\) defines a cosmological functor.

(ii) Specializing (i) to the terminal \(\infty\)-category, each \(\infty\)-cosmos has an **underlying quasi-category** functor \((-)_0 := \text{Fun}(1, -): \mathcal{K} \to \mathcal{QCat}\).

(iii) For any \(\infty\)-cosmos \(\mathcal{K}\) and any simplicial set \(U\), the simplicial cotensor defines a cosmological functor \((-)^U: \mathcal{K} \to \mathcal{K}\).

(iv) For any \(\infty\)-category \(A\) in a cartesian closed \(\infty\)-cosmos \(\mathcal{K}\), exponentiation defines a cosmological functor \((-)^A: \mathcal{K} \to \mathcal{K}\).

(v) For any functor \(f: A \to B\) in an \(\infty\)-cosmos \(\mathcal{K}\), pullback along \(f\) defines a cosmological functor \(f^* : \mathcal{K}_B \to \mathcal{K}_A\).

(vi) For any cosmological functor \(F: \mathcal{K} \to \mathcal{L}\) and any \(A \in \mathcal{K}\), the induced map on slices \(F: \mathcal{K}_A \to \mathcal{L}_{FA}\) defines a cosmological functor.

Proof. The first four of these statements are nearly immediate, the preservation of isofibrations being asserted explicitly as a hypothesis in each case and the preservation of limits following from standard categorical arguments.

For (v), pullback in an \(\infty\)-cosmos \(\mathcal{K}\) is a simplicially enriched limit construction; one consequence of this is that \(f^* : \mathcal{K}_B \to \mathcal{K}_A\) defines a simplicial functor. The action of the functor \(f^*\) on a 0-arrow \(g\) in \(\mathcal{K}_B\) is also defined by a pullback square: since the front and back squares in the displayed diagram

\(^{13}\)See Definition A.2.5.
Since isofibrations are stable under pullback, it follows that \( f^* : \mathcal{K}_B \to \mathcal{K}_A \) preserves isofibrations. It remains to prove that this functor preserves the simplicial limits constructed in Proposition 1.2.22, which is fundamentally a consequence of the commutativity of limit constructions. In each case, this can be verified explicitly. We illustrate this computation for products and simplicial cotensors, by constructing the commutative cubes:

Since the front, back, and right faces are pullbacks, the left is as well, which is what we wanted to show. □

By Propositions 1.2.11 and 1.2.12, the subcategory inclusions \( \text{Cat} \hookrightarrow \text{QCat} \) and \( \text{Kan} \hookrightarrow \text{QCat} \) both define cosmological functors; see also Lemma 6.1.4. These cosmological embeddings will make precise the intuition that the formal category theory of 1-categories or of \( \infty \)-groupoids can be recovered as a special case of the formal category theory of \((\infty,1)\)-categories.

Non-examples of cosmological functors are also instructive:

1.3.4. Non-Example. The forgetful functor \( \mathcal{K}_B \to \mathcal{K} \) is simplicial and preserves the class of isofibrations but does not define a cosmological functor, failing to preserve cotensors and products. However, by Proposition 1.3.3(v), its right adjoint \( - \times B : \mathcal{K} \to \mathcal{K}_B \) does define a cosmological functor.

1.3.5. Non-Example. The cosmological embedding \( \text{Kan} \hookrightarrow \text{QCat} \) has a right adjoint \( (-)^\simeq : \text{QCat} \to \text{Kan} \) that carries each quasi-category to its “groupoid core” or maximal sub Kan complex, the simplicial subset containing those \( n \)-simplices whose edges are all isomorphisms. This “core” functor preserves isofibrations and 1-categorical limits but is not cosmological since it is not simplicially enriched: any functor \( K \to Q \) whose domain is a Kan complex and whose codomain is a quasi-category factors through the inclusion \( Q^\simeq \to Q \) via a unique map \( K \to Q^\simeq \) but in general \( \text{Fun}(K, Q) \neq \text{Fun}(K, Q^\simeq) \), since a natural transformation \( K \times \Delta[1] \to Q \) will only factor through \( Q^\simeq \to Q \) in the case where its components are invertible. See Lemma 12.1.13 however.

Certain cosmological functors are especially well-behaved:

1.3.6. Definition (biequivalences). A cosmological functor defines a biequivalence \( F : \mathcal{K} \Rightarrow \mathcal{L} \) if additionally
(i) it is essentially surjective on objects up to equivalence: for all \( C \in \mathcal{L} \) there exists \( A \in \mathcal{K} \) so that \( FA \simeq C \) and

(ii) it defines a local equivalence: for all \( A, B \in \mathcal{K} \), the action of \( F \) on functor spaces defines an equivalence

\[
\text{Fun}(A, B) \xrightarrow{\sim} \text{Fun}(FA, FB).
\]

Cosmological biequivalences will be studied more systematically in Chapter 10, where we think of them as “change-of-model” functors. Crucially for our proof of the “model-independence” of \((\infty, 1)\)-category theory in Chapter 11, we have a variety of cosmological biequivalences between the \(\infty\)-cosmoi of \((\infty, 1)\)-categories:

1.3.7. Example (biequivalences between \(\infty\)-cosmoi of \((\infty, 1)\)-categories; §E.2).

(i) The underlying quasi-category functors defined on the \(\infty\)-cosmoi of complete Segal spaces, Segal categories, and 1-complicial sets

\[
\begin{align*}
\text{CSS} & \xrightarrow{(-)_0} \text{QCat} \\
\text{Segal} & \xrightarrow{(-)_0} \text{QCat} \\
\text{1-Comp} & \xrightarrow{(-)_0} \text{QCat}
\end{align*}
\]

are all biequivalences. In the first two cases these are defined by “evaluating at the 0th row” and in the last case this is defined by “forgetting the markings.”

(ii) There is also a cosmological biequivalence \(\text{QCat} \xrightarrow{\sim} \text{CSS} \) defined by Joyal and Tierney [62].

(iii) The functor \(\text{CSS} \xrightarrow{\sim} \text{Segal} \) defined by Bergner [13] that “discretizes” a complete Segal spaces also defines a cosmological biequivalence.

(iv) There is a further cosmological biequivalence \(\text{QCat} \xrightarrow{\sim} \text{1-Comp} \) that gives each quasi-category its “natural marking,” with all invertible 1-simplices and all simplices in dimension greater than 1 marked.

In terminology justified by Proposition 10.2.2, we refer to an \(\infty\)-cosmos \(\mathcal{K}\) as an \(\infty\)-cosmos of \((\infty, 1)\)-categories just when the underlying quasi-category \((-)_0: \mathcal{K} \to \text{QCat}\) is a cosmological biequivalence.

1.3.8. Remark. The underlying quasi-category functor \((-)_0: \mathcal{K} \to \text{QCat}\) carries the internal homs of a cartesian closed \(\infty\)-cosmos \(\mathcal{K}\) to the corresponding functor spaces: for any \(\infty\)-categories \(A\) and \(B\) in \(\mathcal{K}\), we have

\[
(B^A)_0 := \text{Fun}(1, B^A) \cong \text{Fun}(A, B).
\]

In the case where the \(\infty\)-cosmos \(\mathcal{K}\) is biequivalent to \(\text{QCat}\), we will see in Chapters 10 and 11 that this entails no essential loss of categorical information.

Cosmological biequivalences not only preserve equivalences but also reflect and create them:

1.3.9. Lemma. Let \( F: \mathcal{K} \xrightarrow{\sim} \mathcal{L} \) be a cosmological biequivalence. Then:

(i) A functor \( f: A \to B \) between \(\infty\)-categories in \(\mathcal{K}\) is an equivalence if and only if \( FF: FA \to FB \) is an equivalence in \(\mathcal{L}\).

(ii) A pair of \(\infty\)-categories in \(\mathcal{K}\) are equivalent if and only if their images in \(\mathcal{L}\) are equivalent.

Proof. Lemma 1.3.2 implies that cosmological functors preserve equivalences and thus also the condition of there being an equivalence between a pair of \(\infty\)-categories in \(\mathcal{K}\). To see that equivalences
are also reflected, suppose \( f : A \to B \) is a functor in \( \mathcal{K} \) with the property that \( Ff : FA \Rightarrow FB \) is an equivalence in \( \mathcal{L} \). Now for any \( \infty \)-category \( X \), simplicial functoriality provides a commutative diagram

\[
\begin{array}{ccc}
\text{Fun}(X, A) & \xrightarrow{F_*} & \text{Fun}(X, B) \\
\downarrow & & \downarrow \\
\text{Fun}(FX, FA) & \xrightarrow{F_*} & \text{Fun}(FX, FB)
\end{array}
\]

so from the 2-of-3 property we conclude that \( F_* : \text{Fun}(X, A) \to \text{Fun}(X, B) \) is an equivalence, proving that \( f \) is an equivalence in \( \mathcal{K} \).

To see that equivalences are created, suppose now that \( A \) and \( B \) are \( \infty \)-categories in \( \mathcal{K} \) equipped with an equivalence:

\[
\begin{array}{ccc}
FA & \overset{\tilde{f}}{\xrightarrow{\sim}} & FB \\
\overset{\tilde{g}}{\xleftarrow{\sim}} & \overset{\tilde{g}}{\xrightarrow{\sim}} & \overset{\tilde{f}}{\xrightarrow{\sim}} \\
FA & \xrightarrow{\tilde{\alpha}} & FA^\mathbb{I} \\
\tilde{g} \overset{\sim}{\xleftarrow{\sim}} & \overset{\sim}{\xrightarrow{\sim}} & \overset{\sim}{\xrightarrow{\sim}} \\
FA & \xrightarrow{\tilde{\beta}} & FB^\mathbb{I} \\
\end{array}
\]

in \( \mathcal{L} \). Since \( \text{Fun}(A, B) \Rightarrow \text{Fun}(FA, FB) \) and \( \text{Fun}(B, A) \Rightarrow \text{Fun}(FB, FA) \) are equivalences of quasi-categories, by Remark 1.1.23 the induced functors between their homotopy categories \( h(\text{Fun}(A, B)) \Rightarrow h(\text{Fun}(FA, FB)) \) and \( h(\text{Fun}(B, A)) \Rightarrow h(\text{Fun}(FB, FA)) \) are equivalences of categories, and in particular essentially surjective. So we may lift \( \tilde{f} \) and \( \tilde{g} \) to functors \( f : A \to B \) and \( g : B \to A \) so that \( Ff \cong \tilde{f} \) and \( Fg \cong \tilde{g} \) in \( h(\text{Fun}(A, B)) \) and \( h(\text{Fun}(B, A)) \) respectively. The commutative diagram

\[
\begin{array}{ccc}
\text{Fun}(B, A) \times \text{Fun}(A, B) & \xrightarrow{\circ} & \text{Fun}(A, A) \\
\downarrow & & \downarrow \\
\text{Fun}(FB, FA) \times \text{Fun}(FA, FB) & \xrightarrow{\circ} & \text{Fun}(FA, FA)
\end{array}
\]

induces a commutative diagram of functors between homotopy categories. In particular, by composing isomorphisms we see that

\[
F(\text{id}_A) = \text{id}_{FA} \cong \tilde{g} \circ \tilde{f} \cong Fg \circ Ff = F(g \circ f)
\]

in \( h(\text{Fun}(A, A)) \). By fully faithfulness of \( h(\text{Fun}(A, A)) \Rightarrow h(\text{Fun}(FA, FA)) \), this isomorphism lifts to an isomorphism \( \text{id}_A \cong g \circ f \) in \( h(\text{Fun}(A, A)) \). By Corollary 1.1.16, this isomorphism can be represented by a homotopy coherent isomorphism \( \mathbb{I} \to \text{Fun}(A, A) \), which internalizes to define a map \( \alpha : A \to A^\mathbb{I} \) as required. The construction of the homotopy coherent isomorphism \( \beta : B \to B^\mathbb{I} \) from \( f \circ g \) to \( \text{id}_B \) proceeds similarly.

The proof of the creation of equivalences in Lemma 1.3.9 is surprisingly delicate, passing to the homotopy categories of the functor spaces to avoid lifting and composing homotopy coherent isomorphisms; an argument along those lines is also possible, and left to the reader as Exercise 1.3.ii. The next section will give context for the argument just given, introducing the homotopy 2-category of an \( \infty \)-cosmos. The reader will then have an opportunity to revisit the creation of equivalences in Exercise 1.4.vii.
Exercises.

1.3.i. **Exercise.** Prove that for any cosmological functor $F : \mathcal{K} \to \mathcal{L}$ and any $A \in \mathcal{K}$, the induced map $F : \mathcal{K}_A \to \mathcal{L}_{FA}$ defines a cosmological functor.

1.3.ii. **Exercise.** Sketch a proof that cosmological biequivalences create equivalences between $\infty$-categories by lifting and composing the homotopy coherent isomorphisms given as part of the data of the hypothesized equivalences, without passing to homotopy categories.

1.3.iii. **Exercise.** Suppose $F : \mathcal{K} \to \mathcal{L}$, $G : \mathcal{L} \to \mathcal{M}$, and $H : \mathcal{M} \to \mathcal{N}$ are cosmological functors, and assume that $GF$ and $HG$ are cosmological biequivalences. Show that $F$, $G$, $H$, and $HGF$ are cosmological biequivalences.

1.4. **The Homotopy 2-Category**

Small 1-categories define the objects of a strict 2-category $\text{Cat}$ of categories, functors, and natural transformations. Many basic categorical notions — those defined in terms of categories, functors, and natural transformations — can be defined internally to the 2-category $\text{Cat}$. This suggests a natural avenue for generalization: reinterpreting these same definitions in a generic 2-category using its objects in place of small categories, its 1-cells in place of functors, and its 2-cells in place of natural transformations.

In Chapter 2, we will develop a non-trivial portion of the theory of $\infty$-categories in any fixed $\infty$-cosmos following exactly this outline, working internally to a strict 2-category that we refer to as the homotopy 2-category that we associate to any $\infty$-cosmos. The homotopy 2-category of an $\infty$-cosmos is a quotient of the full $\infty$-cosmos, replacing each quasi-categorical functor space by its homotopy category. Surprisingly, this rather destructive quotienting operation preserves quite a lot of information. Indeed, essentially all of the development of the theory of $\infty$-categories in Part I takes place in the homotopy 2-category of an $\infty$-cosmos. This said, we caution the reader against becoming overly seduced by homotopy 2-categories. This structure is more of a technical convenience for reducing the complexity of our arguments than a fundamental notion of $\infty$-category theory.

The homotopy 2-category for the $\infty$-cosmos of quasi-categories was first introduced by Joyal in his work on the foundations of quasi-category theory [61].

1.4.1. **Definition (homotopy 2-category).** Let $\mathcal{K}$ be an $\infty$-cosmos. Its **homotopy 2-category** is the strict 2-category $\mathcal{K}^h$ whose

- objects are the the objects $A, B$ of $\mathcal{K}$, i.e., the $\infty$-categories;
- 1-cells $f : A \to B$ are the 0-arrows in the functor space $\text{Fun}(A, B)$, i.e., the $\infty$-functors; and
- 2-cells $\begin{array}{c} A \\ \uparrow a \\downarrow g \\ B \end{array}$ are homotopy classes of 1-simplices in $\text{Fun}(A, B)$, which we call $\infty$-natural transformations.

\[\text{A comprehensive introduction to strict 2-categories appears as Appendix B. Succinctly, in parallel with Digression 1.2.4, 2-categories can be understood equally as}
\]

- “two-dimensional” categories, with objects; 1-cells, whose boundary are given by a pair of objects; and 2-cells, whose boundary are given by a parallel pair of 1-cells between a pair of objects—together with partially-defined composition operations governed by this boundary data
- or as categories enriched over $\text{Cat}$.

See Definition B.1.1 and Exercise 1.4.i.
Put another way, \( \hat{\mathcal{K}} \) is the 2-category with the same objects as \( \mathcal{K} \) and with hom-categories defined by
\[
\text{hFun}(A, B) := h(\text{Fun}(A, B)),
\]
that is, as the homotopy category of the quasi-category \( \text{Fun}(A, B) \).

The underlying category of a 2-category is defined by simply forgetting its 2-cells. Note that an \( \infty \)-cosmos \( \mathcal{K} \) and its homotopy 2-category \( \hat{\mathcal{K}} \) share the same underlying category \( \mathcal{K}_0 \) of \( \infty \)-categories and \( \infty \)-functors in \( \mathcal{K} \).

1.4.2. Digression (change of base §A.7). The homotopy category functor \( h: \text{sSet} \to \text{Cat} \) preserves finite products, as of course does its right adjoint. It follows that the adjunction of Proposition 1.1.11 induces a change-of-base adjunction
\[
\begin{array}{ccc}
2\text{-Cat} & \xleftarrow{h_*} & \text{sSet-Cat} \\
\downarrow & \swarrow & \\
\text{sSet-Cat} & \rightarrow & \text{Cat}
\end{array}
\]
whose left and right adjoints change the enrichment by applying the homotopy category functor or the nerve functor to the hom objects of the enriched category. Here 2\text{-Cat} and s\text{Set-Cat} can each be understood as 2-categories — of enriched categories, enriched functors, and enriched natural transformations — and both change of base constructions define 2-functors; see Propositions A.7.3 and A.7.6. Since the nerve embedding is fully faithful, 2-categories can be identified as a full subcategory comprised of those simplicial categories whose hom-spaces are nerves of categories; see Exercise 1.4.i.

The proof of Lemma 1.3.9 made use of the following observation.

1.4.3. Lemma.

(i) Every 2-cell in the homotopy 2-category of an \( \infty \)-cosmos
\[
A \overset{f}{\underset{g}{\Rightarrow}} B
\]
is represented by a map \( ^\alpha \cdot: 2 \to \text{Fun}(A, B) \) or equivalently by a functor \( ^\alpha \cdot: A \to B^2 \), and two such maps represent the same 2-cell if and only if their images are homotopic as 1-simplices in \( \text{Fun}(A, B) \).

(ii) Every invertible 2-cell in the homotopy 2-category of an \( \infty \)-cosmos
\[
A \overset{f}{\underset{g}{\Rightarrow}} B
\]
is represented by a map \( ^\alpha \cdot: \mathbb{I} \to \text{Fun}(A, B) \) or equivalently by a functor \( ^\alpha \cdot: A \to B^\mathbb{I} \), and two such maps represent the same invertible 2-cell if and only if their common restrictions along \( 2 \hookrightarrow \mathbb{I} \) are homotopic as 1-simplices in \( \text{Fun}(A, B) \).

The notion of homotopic 1-simplices referenced here is defined in Lemma 1.1.9.

Proof. The first statement is immediately from the definition of the 2-cells in the homotopy 2-category and the universal property (1.2.7) of the simplicial cotensor. Now a 2-cell in a 2-category is invertible if and only if it defines an isomorphism in the appropriate hom-category \( h\text{Fun}(A, B) \). By Definition 1.1.13 and Corollary 1.1.16 it follows that each invertible 2-cell in \( \hat{\mathcal{K}} \) is represented by a homotopy coherent isomorphism \( \mathbb{I} \to \text{Fun}(A, B) \), which similarly internalizes to define a functor. \( \square \)
An upshot of Digression 1.4.2 is that change of base is an operation that applies to enriched functors as well as enriched categories, as can be directly verified in the case of greatest interest:

1.4.4. **Lemma.** Any simplicial functor $F: \mathcal{K} \to \mathcal{L}$ between $\infty$-cosmoi induces a 2-functor $\mathbf{h}\mathcal{K} \to \mathbf{h}\mathcal{L}$ between their homotopy 2-categories.

**Proof.** The action of the induced 2-functor $F: \mathbf{h}\mathcal{K} \to \mathbf{h}\mathcal{L}$ on objects and 1-cells is given by the corresponding action of $F: \mathcal{K} \to \mathcal{L}$; recall an $\infty$-cosmos and its homotopy 2-category have the same underlying 1-category. Each 2-cell in $\mathbf{h}\mathcal{K}$ is represented by a 1-simplex in $\text{Fun}(A,B)$ which is mapped via

$$
\begin{array}{ccc}
\text{Fun}(A,B) & \xrightarrow{F} & \text{Fun}(FA,FB) \\
A & \xrightarrow{f} & FA \\
\downarrow{g} & & \downarrow{Fg} \\
B & \rightarrow{Ff} & FB
\end{array}
$$

to a 1-simplex representing a 2-cell in $\mathbf{h}\mathcal{L}$. Since the action $F: \text{Fun}(A,B) \to \text{Fun}(FA,FB)$ on functor spaces defines a morphism of simplicial sets, it preserves faces and degeneracies. In particular, homotopic 1-simplices in $\text{Fun}(A,B)$ are carried to homotopic 1-simplices in $\text{Fun}(FA,FB)$ so the action on 2-cells just described is well-defined. The 2-functoriality of these mappings follows from the simplicial functoriality of the original mapping. □

We now begin to relate the simplicially enriched structures of an $\infty$-cosmos to the 2-categorical structures in its homotopy 2-category. The first result proves that homotopy 2-categories inherit products from their $\infty$-cosmoi, which satisfy a 2-categorical universal property. To illustrate, recall that the terminal $\infty$-category $1 \in \mathcal{K}$ has the universal property $\text{Fun}(X,1) \cong 1$ for all $X \in \mathcal{K}$. Applying the homotopy category functor we see that $1 \in \mathbf{h}\mathcal{K}$ has the universal property $\text{hFun}(X,1) \cong 1$ for all $X \in \mathbf{h}\mathcal{K}$, which is expressed by saying that the $\infty$-category 1 defines a 2-terminal object in the homotopy 2-category. This 2-categorical universal property has both a 1-dimensional and a 2-dimensional aspect. Since $\text{hFun}(X,1) \cong 1$ is a category with a single object, there exists a unique morphism $X \to 1$ in $\mathcal{K}$. And since $\text{hFun}(X,1) \cong 1$ has only a single morphism, we see that the only 2-cells in $\mathbf{h}\mathcal{K}$ with codomain 1 are identities.

1.4.5. **Proposition (cartesian (closure)).**

(i) The homotopy 2-category of any $\infty$-cosmos has 2-categorical products.

(ii) The homotopy 2-category of a cartesian closed $\infty$-cosmos is cartesian closed as a 2-category.

**Proof.** While the functor $h: s\text{Set} \to \text{Cat}$ only preserves finite products, the restricted functor $h: Q\text{Cat} \to \text{Cat}$ preserves all products on account of the simplified description of the homotopy category of a quasi-category given in Lemma 1.1.12; see Exercise 1.2.iii. Thus for any set $I$ and family of $\infty$-categories $(A_i)_{i \in I}$ in $\mathcal{K}$, the homotopy category functor carries the isomorphism of quasi-categories displayed below left to an isomorphisms of hom-categories displayed below right

$$
\begin{array}{c}
\text{Fun}(X, \prod_{i \in I} A_i) \xrightarrow{\cong} \prod_{i \in I} \text{Fun}(X, A_i) \\
\text{hFun}(X, \prod_{i \in I} A_i) \xrightarrow{\cong} \prod_{i \in I} \text{hFun}(X, A_i).
\end{array}
$$

This proves that the homotopy 2-category $\mathbf{h}\mathcal{K}$ has products whose universal properties have both a 1- and 2-dimensional component, as described for terminal objects above.
If \( \mathcal{K} \) is a cartesian closed \( \infty \)-cosmos, then for any triple of \( \infty \)-categories \( A, B, C \in \mathcal{K} \) there exist exponential objects \( C^A, C^B \in \mathcal{K} \) characterized by natural isomorphisms

\[
\text{Fun}(A \times B, C) \cong \text{Fun}(A, C^B) \cong \text{Fun}(B, C^A).
\]

Passing to homotopy categories we have natural isomorphisms

\[
h\text{Fun}(A \times B, C) \cong h\text{Fun}(A, C^B) \cong h\text{Fun}(B, C^A),
\]

which demonstrates that \( h\mathcal{K} \) is cartesian closed as a 2-category: functors \( A \times B \to C \) transpose to define functors \( A \to C^B \) and \( B \to C^A \), and 2-cells transpose similarly. \( \Box \)

There is a standard definition of isomorphism between two objects in any 1-category, preserved by any functor. Similarly, there is a standard definition of equivalence between two objects in any 2-category, preserved by any 2-functor:

1.4.6. Definition (equivalence). An equivalence in a 2-category is given by

- a pair of objects \( A \) and \( B \)
- a pair of 1-cells \( f : A \to B \) and \( g : B \to A \)
- a pair of invertible 2-cells

\[
\begin{array}{c}
A \\
\Downarrow g f
\end{array} \cong
\begin{array}{c}
\Downarrow \alpha
A
\end{array} \cong
\begin{array}{c}
f g
\Downarrow \beta
A
\end{array}
B
\end{array}
\]

When \( A \) and \( B \) are equivalent, we write \( A \cong B \) and refer to the 1-cells \( f \) and \( g \) as equivalences, denoted by \( \sim \to \).

In the case of the homotopy 2-category of an \( \infty \)-cosmos we have a competing definition of equivalence from 1.2.1: namely a 1-cell \( f : A \Rightarrow B \) that induces an equivalence \( f_* : \text{Fun}(X, A) \Rightarrow \text{Fun}(X, B) \) on functor spaces — or equivalently, by Lemma 1.2.18, a homotopy equivalence defined relative to the interval \( \mathbb{I} \). Crucially, all three notions of equivalence coincide:

1.4.7. Theorem (equivalences are equivalences). In any \( \infty \)-cosmos \( \mathcal{K} \), the following are equivalent and characterize what it means for a functor \( f : A \to B \) between \( \infty \)-categories to define an equivalence.

- (i) For all \( X \in \mathcal{K} \), the post-composition map \( f_* : \text{Fun}(X, A) \Rightarrow \text{Fun}(X, B) \) defines an equivalence of quasi-categories.
- (ii) There exists a functor \( g : B \to A \) and natural isomorphisms \( \alpha : \text{id}_A \cong gf \) and \( \beta : fg \cong \text{id}_B \) in the homotopy 2-category.
- (iii) There exists a functor \( g : B \to A \) and homotopies

\[
\begin{array}{c}
A \\
\Downarrow g f
\end{array} \Rightarrow
\begin{array}{c}
A^\mathbb{I}
\Downarrow \alpha
\Downarrow \text{ev}_0
\end{array},
\begin{array}{c}
A \\
\Downarrow \text{ev}_1
\end{array} \Rightarrow
\begin{array}{c}
A
\Downarrow g f
\end{array}
\]

\[
\begin{array}{c}
B \\
\Downarrow \beta
\Downarrow \text{ev}_0
\end{array} \Rightarrow
\begin{array}{c}
B^\mathbb{I}
\Downarrow \beta
\Downarrow \text{ev}_1
\end{array},
\begin{array}{c}
B \\
\Downarrow \text{ev}_1
\end{array} \Rightarrow
\begin{array}{c}
B
\Downarrow \beta
\Downarrow \text{ev}_1
\end{array}
\end{array}
\]

in the \( \infty \)-cosmos in \( \mathcal{K} \).
As an illustrative comparison of 2-categorical and quasi-categorical techniques, rather than appealing to Lemma 1.2.18, we re-prove it.

**Proof.** For (i) ⇒ (ii), if the induced map on post-composition \( f_* : \text{Fun}(X, A) \Rightarrow \text{Fun}(X, B) \) defines an equivalence of quasi-categories, then by Remark 1.1.23, \( f_* : \text{hFun}(X, A) \Rightarrow \text{hFun}(X, B) \) defines an equivalence of categories. In particular, \( f_* : \text{hFun}(B, A) \Rightarrow \text{hFun}(B, B) \) is essentially surjective so there exists \( g \in \text{hFun}(B, A) \) and an isomorphism \( \beta : fg \cong \text{id}_B \in \text{hFun}(B, B) \). Now since \( f_* : \text{hFun}(A, A) \Rightarrow \text{hFun}(A, B) \) is fully faithful, the isomorphism \( \beta f : fgf \cong f \in \text{hFun}(A, B) \) can be lifted to define an isomorphism \( \alpha^{-1} : gf \cong \text{id}_A \in \text{hFun}(A, A) \). This defines the data of a 2-categorical equivalence in Definition 1.4.6.

To see that (ii) ⇒ (iii) recall from Lemma 1.4.3 that the natural isomorphisms \( \alpha : \text{id}_A \cong gf \) and \( \beta : fg \cong \text{id}_B \) in \( \mathfrak{K} \) are represented by maps \( \alpha : A \rightarrow A^\| \) and \( \beta : B \rightarrow B^\| \) in \( \mathcal{K} \) as in (1.2.19).

Finally, (iii) ⇒ (i) since \( \text{Fun}(X, -) \) carries the data of (iii) to the data of an equivalence of categories as in Definition 1.1.22. □

1.4.8. **Digression** (on the significance of Theorem 1.4.7). It is hard to overstate the importance of Theorem 1.4.7 to the work that follows. The categorical constructions that we will introduce for \( \infty \)-categories, \( \infty \)-functors, and \( \infty \)-natural transformations are invariant under 2-categorical equivalence in the homotopy 2-category and the universal properties we develop similarly characterize 2-categorical equivalence classes of \( \infty \)-categories. Theorem 1.4.7 then asserts that such constructions are "homotopically correct": both invariant under equivalence in the \( \infty \)-cosmos and precisely identifying equivalence classes of objects.

The equivalence invariance of the functor space in the codomain variable is axiomatic, but equivalence invariance in the domain variable is not.²⁵ Nor is it evident how this could be proven from either (i) or (iii) of Theorem 1.4.7.

But using (ii) and 2-categorical techniques, there is now a short proof:

1.4.9. **Corollary.** Equivalences of \( \infty \)-categories \( A' \Rightarrow A \) and \( B \Rightarrow B' \) induce an equivalence of functor spaces \( \text{Fun}(A, B) \Rightarrow \text{Fun}(A', B') \).

**Proof.** The simplicial functors \( \text{Fun}(A, -) : \mathcal{K} \rightarrow \mathcal{QC} \) and \( \text{Fun}(-, B) : \mathcal{K}^\text{op} \rightarrow \mathcal{QC} \) induce 2-functors \( \text{Fun}(A, -) : \mathfrak{hK} \rightarrow \mathfrak{hQC} \) and \( \text{Fun}(-, B) : \mathfrak{hK}^\text{op} \rightarrow \mathfrak{hQC} \), which preserve the 2-categorical equivalences of Definition 1.4.6. By Theorem 1.4.7 this is what we wanted to show. □

There is also a standard 2-categorical notion of an isofibration, defined in the statement of Proposition 1.4.10 and elaborated upon in Definition B.4.4. We now show that any isofibration in an \( \infty \)-cosmos defines an isofibration in its homotopy 2-category.²⁶

1.4.10. **Proposition** (isofibrations define isofibrations). Any isofibration \( p : E \Rightarrow B \) in an \( \infty \)-cosmos \( \mathcal{K} \) also defines an isofibration in the homotopy 2-category \( \mathfrak{hK} \): given any invertible 2-cell as displayed below left abutting to \( B \) with a specified lift of one of its boundary 1-cells through \( p \), there exists an invertible 2-cell

²⁵Lemma 1.3.2 does not apply since \( \text{Fun}(-, B) \) is not cosmological.

²⁶The converse does not hold, however, nor is it the case that a representably-defined isofibration of quasi-categories is necessarily an isofibration in the \( \infty \)-cosmos; consider the case of sliced \( \infty \)-cosmoi for instance.
abutting to $E$ with this boundary 1-cell as displayed below right that whiskers with $p$ to the original 2-cell.

\[
\begin{array}{ccc}
X & \overset{e}{\longrightarrow} & E \\
\downarrow^{\cong \llp} & & \downarrow^{p} \\
B & \underset{\beta}{\longrightarrow} & B
\end{array}
= \begin{array}{ccc}
X & \overset{e}{\longrightarrow} & E \\
\downarrow^{\cong \llp} & & \downarrow^{p} \\
B & \underset{\gamma}{\longrightarrow} & B
\end{array}
\]

**Proof.** Put another way, the universal property of the statement says that the functor

\[ p_* : h\text{Fun}(X, E) \to h\text{Fun}(X, B) \]

is an isofibration of categories in the sense defined in Proposition 1.2.11. By axiom 1.2.1(ii), since $p : E \to B$ is an isofibration in $\mathcal{K}$, the induced map $p_* : \text{Fun}(X, E) \to \text{Fun}(X, B)$ is an isofibration of quasi-categories. So it suffices to show that the functor $h : \mathcal{QCat} \to \mathcal{Cat}$ carries isofibrations of quasi-categories to isofibrations of categories.

So let us now consider an isofibration $p : E \to B$ between quasi-categories. By Corollary 1.1.16, every isomorphism $\beta$ in the homotopy category $hB$ of the quasi-category $B$ is represented by a simplicial map $\beta : \mathbb{I} \to B$. By Definition 1.1.17, the lifting problem

\[
\begin{array}{ccc}
\mathbb{I} & \overset{e}{\longrightarrow} & E \\
\downarrow^{\gamma} & & \downarrow^{p} \\
\mathbb{I} & \underset{\beta}{\longrightarrow} & B
\end{array}
\]

can be solved, and the map $\gamma : \mathbb{I} \to E$ so-produced represents a lift of the isomorphism from $hB$ to an isomorphism in $hE$ with domain $e$. \hfill \Box

1.4.11. **Convention** (on “isofibrations” in homotopy 2-categories). Since the converse to Proposition 1.4.10 does not hold, there is a potential ambiguity when using the term “isofibration” to refer to a map in the homotopy 2-category of an $\infty$-cosmos. We adopt the convention that when we declare that a map in $h\mathcal{K}$ is an isofibration we always mean this is the stronger sense of defining an isofibration in $\mathcal{K}$. This stronger condition gives us access to the 2-categorical lifting property of Proposition 1.4.10 but also to the many homotopical properties axiomatized in Definition 1.2.1, which guarantee that the strictly defined limits of 1.2.1(i) are automatically equivalence-invariant constructions, as shown in §C.1 and Proposition 6.3.1.

We conclude this chapter with a final definition that can be extracted from the homotopy 2-category of an $\infty$-cosmos. The 1- and 2-cells in the homotopy 2-category from the terminal $\infty$-category $1 \in \mathcal{K}$ to a generic $\infty$-category $A \in \mathcal{K}$ define the objects and morphisms in the homotopy category of the $\infty$-category $A$.

1.4.12. **Definition** (homotopy category of an $\infty$-category). The **homotopy category** of an $\infty$-category $A$ in an $\infty$-cosmos $\mathcal{K}$ is defined to be the homotopy category of its underlying quasi-category, that is:

\[ hA := h\text{Fun}(1, A) := h(\text{Fun}(1, A)). \]

As we shall discover, homotopy categories generally bear “derived” analogues of structures present at the level of $\infty$-categories. An early example of this appears as a remark after the statement of Proposition 2.1.7.

\footnote{Alternately, argue directly using Lemma 1.4.3.}
Exercises.

1.4.i. Exercise. Consider a diagram of identity-on-objects functors (1.2.5) defining a simplicial category \( \mathcal{A} \) as described in Digression 1.2.4 and Exercise 1.2.i. Show that the hom-spaces in this simplicial category are nerves of categories, and thus \( \mathcal{A} \) defines a 2-category, if and only if \( \mathcal{A}_n \colon \Delta^{op} \to \text{Cat} \) satisfies the Segal condition: for each \( n \geq 2 \), the canonical map

\[
\mathcal{A}_n \to \mathcal{A}_1 \times \cdots \times \mathcal{A}_1,
\]
whose codomain is the wide pullback of \( n \) copies of \( \mathcal{A}_1 \) along alternating instances of the maps \( \delta_0, \delta_1 : \mathcal{A}_1 \to \mathcal{A}_0 \), is an isomorphism.\(^{28}\)

1.4.ii. Exercise. (i) What is the homotopy 2-category of the \( \infty \)-cosmos \( \text{Cat} \) of 1-categories?

(ii) Prove that the nerve defines a 2-functor \( \text{Cat} \to \mathcal{hQCat} \) that is locally fully faithful.

1.4.iii. Exercise. Demonstrate that the homotopy 2-category of the dual cosmos \( \mathcal{K}^\circ \) of an \( \infty \)-cosmos \( \mathcal{K} \) is the co-dual of the homotopy 2-category \( \mathcal{hK} \), with the domains and codomains of 2-cells but not 1-cells reversed: in symbols \( \mathcal{h}(\mathcal{K}^\circ) \cong (\mathcal{hK})^\circ \).

1.4.iv. Exercise. Consider a natural isomorphism

\[
\begin{array}{c}
A \\
\downarrow^f \\
\downarrow^g \\
B
\end{array}
\]

between a parallel pair of functors in an \( \infty \)-cosmos. Give two proofs that if either \( f \) or \( g \) is an equivalence then both functors are, either by arguing entirely in the homotopy 2-category or by appealing to Lemma 1.4.3.

1.4.v. Exercise. Extend Lemma 1.2.27 to show that the following four conditions are equivalent, characterizing the discrete objects \( E \) in an \( \infty \)-cosmos \( \mathcal{K} \):

(i) \( E \) is a discrete object in the homotopy 2-category \( \mathcal{hK} \), that is, every 2-cell with codomain \( E \) is invertible.

(ii) For each \( X \in \mathcal{K} \), the hom-category \( \text{hFun}(X, E) \) is a groupoid.

(iii) For each \( X \in \mathcal{K} \), the mapping quasi-category \( \text{Fun}(X, E) \) is a Kan complex.

(iv) The isofibration \( E^I \to E^2 \), induced by the inclusion of simplicial sets \( 2 \hookrightarrow I \), is a trivial fibration.

1.4.vi. Exercise (10.3.1). Extend Lemma 1.4.4 to show that if \( F : \mathcal{K} \to \mathcal{L} \) is a cosmological biequivalence then \( F : \mathcal{hK} \to \mathcal{hL} \) is a 2-categorical biequivalence, a 2-functor that is essentially surjective on objects up to equivalence that locally defines an equivalence of hom-categories.

1.4.vii. Exercise. Let \( F : \mathcal{K} \cong \mathcal{L} \) be a cosmological biequivalence and let \( A, B \in \mathcal{K} \). Re-prove part of the statement of Lemma 1.3.9: that if \( FA \cong FB \) in \( \mathcal{L} \) then \( A \cong B \) in \( \mathcal{K} \).

1.4.viii. Exercise. Let \( B \) be an \( \infty \)-category in the \( \infty \)-cosmos \( \mathcal{K} \) and let \( \mathcal{hK}_B \) denote the 2-category whose

\(^{28}\)An additional exercise, for readers familiar with the definition of a 2-category as a category internal to \( \text{Cat} \) whose “category of objects” is discrete, is to compare that definition to this one.
• objects are isofibrations $E \to B$ in $\mathcal{K}$ with codomain $B$
• 1-cells are 1-cells in $\mathcal{h}\mathcal{K}$ over $B$

![Diagram 1]

• 2-cells are 2-cells $\alpha$ in $\mathcal{h}\mathcal{K}$

![Diagram 2]

that lie over $B$ in the sense that $q\alpha = \text{id}_p$.

Argue that the homotopy 2-category $\mathcal{h}(\mathcal{K}/B)$ of the sliced $\infty$-cosmos has the same underlying 1-category but different 2-cells. How do these compare with the 2-cells of $\mathcal{h}\mathcal{K}/B$?\(^{29}\)

\(^{29}\)A more systematic comparison appears in Proposition 3.6.2.
CHAPTER 2

Adjunctions, Limits, and Colimits I

Heuristically, $\infty$-categories generalize ordinary 1-categories by adding in higher dimensional morphisms and weakening the composition law. One could imagine “$\infty$-tizing” other types of categorical structure similarly, by adding in higher dimension and weakening properties. The naïve hope would then be that proofs establishing the theory of 1-categories might similarly generalize to give proofs for $\infty$-categories, just by adding a prefix “$\infty$-” everywhere. In this chapter, we make this dream a reality—at least for a library of basic propositions concerning equivalences, adjunctions, limits, and colimits and the relationships between these notions.

Recall that categories, functors, and natural transformations assemble into a 2-category $\mathcal{C}at$. Similarly, the $\infty$-categories, $\infty$-functors, and $\infty$-natural transformations in any $\infty$-cosmos assemble into a 2-category, namely the homotopy 2-category of the $\infty$-cosmos, introduced in §1.4. In fact, by Exercise 1.4.ii, $\mathcal{C}at$ can be regarded as a special case of a homotopy 2-category. In this chapter, we will use strict 2-categorical techniques to define adjunctions between $\infty$-categories and limits and colimits of diagrams valued in an $\infty$-category and prove that these notions interact in the expected ways. In the homotopy 2-category of categories, this recovers classical results from 1-category theory, and in some cases even specializes to the standards proofs. As these proofs are equally valid in any homotopy 2-category, our arguments also establish the desired generalizations by simply appending the prefix “$\infty$-.”

In §2.1, we define an adjunction between $\infty$-categories to be an adjunction in the homotopy 2-category of $\infty$-categories, $\infty$-functors, and $\infty$-natural transformations. While it takes some work, relegated to §F.5, to justify the moral correctness of this simple definition it has the great advantage that proofs of a number of results concerning the calculus of adjunctions and equivalences can be taken “off the shelf” in the sense that anyone who is sufficiently well-acquainted with 2-categories might know them already. In §2.2, we specialize the theory of adjunctions between $\infty$-categories to define and study initial and terminal elements inside an $\infty$-category. This section also serves as a warmup for the more subtle general theory of limits and colimits of diagrams valued in an $\infty$-category, which is the subject of §2.3. Finally, in §2.4, we study the interactions between these notions, proving that right adjoints preserve limits and left adjoints preserve colimits.

Missing from this discussion is an account of the universal properties associated to the unit of an adjunction or to a limit cone. These will be incorporated when we return to these topics in Chapter 4 after introducing an appropriate “hom $\infty$-category” with which to state them.

2.1. Adjunctions and Equivalences

In §1.4, we encountered the definition of an equivalence between a pair of objects in a 2-category. In the case where the ambient 2-category is the homotopy 2-category of an $\infty$-cosmos, we observed in Theorem 1.4.7 that the 2-categorical notion of equivalence precisely recaptures the notion of equivalence introduced in Definition 1.2.1 between $\infty$-categories in the full $\infty$-cosmos. In each of the examples of $\infty$-cosmoi we have considered, the representably-defined equivalences in the $\infty$-cosmos coincide with
the standard notion of equivalences between ∞-categories as presented in that particular model.¹ Thus, the 2-categorical notion of equivalence is the “correct” notion of equivalence between ∞-categories.

Similarly, there is a standard definition of an adjunction between a pair of objects in a 2-category, which, when interpreted in the homotopy 2-category of ∞-categories, functors, and natural transformations in an ∞-cosmos, will define the correct notion of adjunction between ∞-categories.

2.1.1. Definition (adjunction). An adjunction between ∞-categories is comprised of:

- a pair of ∞-categories A and B,
- a pair of ∞-functors \( u : A \to B \) and \( f : B \to A \),
- and a pair of ∞-natural transformations \( \eta : 1_B \Rightarrow uf \) and \( \epsilon : fu \Rightarrow 1_A \), called the unit and counit respectively,

so that the triangle equalities hold:\²

\[
\begin{array}{cccc}
& u & B & \Rightarrow & B \\
& & \downarrow & \eta & \Rightarrow f \\
A & f & \Rightarrow & u \\
& & \downarrow & \epsilon & \Rightarrow 1 \\
& & u & \downarrow & \eta \\
& A & \Rightarrow & A \\
\end{array}
\]

\[
\begin{array}{cccc}
& B & \Rightarrow & B \\
& \downarrow & \eta & \Rightarrow u \\
A & \Rightarrow & A \\
& f & \Rightarrow & u \\
& \downarrow & \epsilon & \Rightarrow \eta \\
& B & \Rightarrow & B \\
\end{array}
\]

The functor \( f \) is called the left adjoint and \( u \) is called the right adjoint, a relationship that is denoted symbolically in text by writing \( f \dashv u \) or in a displayed diagram such as:\³

\[
\begin{array}{ccc}
A & \xleftarrow{\eta} & B \\
& \downarrow & \Rightarrow \\
& f & \xrightarrow{\epsilon} & u \\
\end{array}
\]

In the future, we generally drop the prefix “∞”- from the functors and natural transformations between ∞-categories.

2.1.2. Digression (why this is the correct definition). For readers who find Definition 2.1.1 implausible — perhaps too simple to be trusted — we offer a few words of justification. Joyal was the first to propose the use of the standard 2-categorical definition of an adjunction, defining an adjunction between quasi-categories to be an adjunction in (what we call) the homotopy 2-category \( \mathcal{HQCAt} \) in the preface to [61]. However, this definition was not widely adopted, with most practitioners instead using Lurie’s definition of adjunction between quasi-categories [74, §5.2], which takes a quite different form. In Appendix F, we prove that in the ∞-cosmos of quasi-categories, Joyal’s 2-categorical definition of adjunction precisely recovers Lurie’s. As explained in Part III, each of the models of \((\infty, 1)\)-categories described in Example 1.2.24 “has the same category theory,” so Definition 2.1.1 agrees with the community consensus notion of adjunction between \((\infty, 1)\)-categories.

But what about those ∞-cosmoi whose objects model \((\infty, n)\)- or \((\infty, \infty)\)-categories? For instance in the ∞-cosmos of complicial sets, the adjunctions defined in the homotopy 2-category are the “pseudo-style” adjunctions. While these are not the most general adjunctions that might be considered — for instance, one could have the triangle equality relations satisfied only up to coherent non-invertible

¹For instance, as outlined in Digression 1.2.13, the equivalences in the ∞-cosmoi of Example 1.2.24 recapture the weak equivalences between fibrant-cofibrant objects in the usual model structure.

²The left-hand equality of pasting diagrams asserts the composition relation \( u \epsilon \cdot \eta u = \text{id}_u \) in the hom-category \( \mathcal{HFun}(A, B) \), while the right-hand equality asserts that \( \epsilon f \cdot f \eta = \text{id}_f \) in \( \mathcal{HFun}(B, A) \). Appendix B and in particular §B.1 are included for the reader who is unfamiliar with the calculus of pasting diagrams.

³Some authors contort adjunction diagrams so that the left adjoint is always oriented in a particular direction; we instead use the turnstile symbol “⊥” to indicate which adjoint is the left adjoint.
3-cells — they are an important class of adjunctions. One reason for the relevance of Definition 2.1.1 in all ∞-cosmoi is its formal properties vis-a-vis the related notion of equivalence, which Theorem 1.4.7 has established is morally “correct,” and with the notions of limits and colimits to be introduced.

Finally, a reasonable objection is that Definition 2.1.1 appears too “low dimensional,” comprised of data found entirely in the homotopy 2-category and ignoring the higher dimensional morphisms in an ∞-cosmos. In fact, any adjunction between ∞-categories extends to a homotopy coherent adjunction involving data in all dimensions, and moreover such extensions are homotopically unique [104].

The definition of an adjunction given in Definition 2.1.1 is “equational” in character: stated in terms of the objects, 1-cells, and 2-cells of a 2-category and their composites. Immediately:

2.1.3. Lemma. Adjunctions in a 2-category are preserved by any 2-functor.

Lemma 2.1.3 provides an easy source of examples of adjunctions between quasi-categories. The 2-functors underlying the cosmological functors of Example 1.3.7 then transfer adjunctions defined in one model of (∞, 1)-categories to adjunctions defined in each of the other models.

2.1.4. Example (adjunctions between 1-categories). Via the nerve embedding $\text{Cat} \hookrightarrow \mathcal{hQCat}$, any adjunction between 1-categories induces an adjunction between their nerves regarded as quasi-categories.

2.1.5. Example (adjunctions between topological categories). Cordier’s homotopy coherent nerve construction [29, 30] defines a 2-functor $\mathcal{R} : \text{Kan-Cat} \to \mathcal{hQCat}$ from the 2-category of Kan complex enriched categories, simplicially enriched functors, and simplicial natural transformations, to the homotopy 2-category $\mathcal{hQCat}$. In this way, topologically enriched adjunctions define adjunctions between quasi-categories.

2.1.6. Example (Quillen adjunctions). Topologically enriched adjunctions are relatively rare. More prevalent are “up-to-homotopy” topologically enriched adjunctions, such as those given by Quillen adjunctions between (simplicial) model categories. These also define adjunctions between quasi-categories; see a proof of Mazel-Gee [83] or [103, §6.2].

The preservation of adjunctions by 2-functors, such as those given by Lemma 1.4.4, proves:

2.1.7. Proposition. Given any adjunction $A \xleftarrow{\perp} B$ between ∞-categories then:

(i) for any ∞-category $X$,

\[
\begin{array}{ccc}
\text{Fun}(X, A) & \perp & \text{Fun}(X, B) \\
\downarrow \quad \circlearrowleft & & \downarrow \quad \circlearrowleft \\
\text{hFun}(X, A) & \perp & \text{hFun}(X, B)
\end{array}
\]

defines an adjunction between quasi-categories;

(ii) for any ∞-category $X$,

\[
\begin{array}{ccc}
\text{Fun}(X, A) & \perp & \text{Fun}(X, B) \\
\downarrow \quad \circlearrowleft & & \downarrow \quad \circlearrowleft \\
\text{hFun}(X, A) & \perp & \text{hFun}(X, B)
\end{array}
\]

defines an adjunction between categories;
(iii) for any simplicial set $U$,

$$
\begin{array}{c}
A^U & \xleftarrow{\parallel_f^U} & B^U \\
\downarrow & \parallel_u^U & \\
\downarrow & \parallel & \\
A^U & \xleftarrow{\perp} & B^U
\end{array}
$$

defines an adjunction between $\infty$-categories;

(iv) and if the ambient $\infty$-cosmos is cartesian closed, then for any $\infty$-category $C$,

$$
\begin{array}{c}
A^C & \xleftarrow{\parallel_f^C} & B^C \\
\downarrow & \parallel_u^C & \\
\downarrow & \parallel & \\
A^C & \xleftarrow{\perp} & B^C
\end{array}
$$

defines an adjunction between $\infty$-categories.

For instance, taking $X = 1$ in (ii) yields a “derived” adjunction between the homotopy categories of the $\infty$-categories $A$ and $B$ introduced in Definition 1.4.12:

$$
\begin{array}{c}
hA & \xleftarrow{\parallel_{f_*}} & hB \\
\downarrow & \parallel_{u_*} & \\
\downarrow & \parallel & \\
hA & \xleftarrow{\perp} & hB
\end{array}
$$

Proof. Any adjunction $f \dashv u$ in the homotopy 2-category $\mathcal{h}K$ is preserved by the 2-functors $\text{Fun}(X, -) : \mathcal{h}K \to \mathcal{h}QCat$, $\text{hFun}(X, -) : \mathcal{h}K \to \text{Cat}$, $(-)^U : \mathcal{h}K \to \mathcal{h}K$, and $(-)^C : \mathcal{h}K \to \mathcal{h}K$. □

2.1.8. Remark. There are contravariant versions of each of the adjunction-preservation results of Proposition 2.1.7, the first of which we explain in detail; see Exercise 2.1.i for further discussion. Fixing the codomain variable of the functor space at any $\infty$-category $C \in \mathcal{K}$ defines a 2-functor

$$
\text{Fun}(\cdot, C) : \mathcal{h}K^{\text{op}} \to \mathcal{h}QCat
$$

that is contravariant on 1-cells and covariant on 2-cells.$^4$ Such 2-functors preserve adjunctions, but exchange left and right adjoints: for instance, given $f \dashv u$ in $K$, we obtain an adjunction

$$
\begin{array}{c}
\text{Fun}(A, C) & \xleftarrow{\parallel_{u^*}} & \text{Fun}(B, C) \\
\downarrow & \parallel_{f^*} & \\
\downarrow & \parallel & \\
\text{Fun}(A, C) & \xleftarrow{\perp} & \text{Fun}(B, C)
\end{array}
$$

between the functor spaces.

The next five results have standard proofs that can be taken “off the shelf” by querying any 2-category theorist who may happen to be standing nearby. The only novelty is the observation that these standard arguments can be applied to the theory of adjunctions between $\infty$-categories.

$^4$On a strict 2-category, the superscript “op” is used to signal that the 1-cells should be reversed but not the 2-cells, the superscript “co” is used to signal that the 2-cells should be reversed but not the 1-cells, and the superscript “coop” is used to signal that both the 1- and 2-cells should be reversed; see Definition B.1.6.
2.1.9. PROPOSITION. Adjunctions compose: given adjoint functors

the composite functors are adjoint.

PROOF. Writing $\eta : \text{id}_B \Rightarrow uf$, $\epsilon : fu \Rightarrow \text{id}_A$, $\eta' : \text{id}_C \Rightarrow u'f'$, and $\epsilon' : f'u' \Rightarrow \text{id}_B$ for the respective units and counits, the pasting diagrams

define the unit and counit of $ff' \dashv u'u$ so that the triangle equalities

hold.

An adjoint to a given functor is unique up to natural isomorphism:

2.1.10. PROPOSITION (uniqueness of adjoints).

(i) If $f \dashv u$ and $f' \dashv u$, then $f \cong f'$.

(ii) Conversely, if $f \dashv u$ and $f \cong f'$ then $f' \dashv u$.

PROOF. Writing $\eta : \text{id}_B \Rightarrow uf$, $\epsilon : fu \Rightarrow \text{id}_A$, $\eta' : \text{id}_B \Rightarrow uf'$, and $\epsilon' : f'u' \Rightarrow \text{id}_A$ for the respective units and counits, the pasting diagrams

define 2-cells $f \Rightarrow f'$ and $f' \Rightarrow f$. The composites $f \Rightarrow f' \Rightarrow f$ and $f' \Rightarrow f \Rightarrow f'$ are computed by pasting these diagrams together horizontally on one side or on the other. Applying the triangle equalities for the adjunctions $f \dashv u$ and $f' \dashv u$ both composites are easily seen to be identities. Hence $f \cong f'$ as functors from $B$ to $A$.

Part (ii) is left as Exercise 2.1.ii.

The following result weakens the hypotheses of Definition 2.1.1.
2.1.11. Lemma (minimal adjunction data). A pair of functors \( f : B \to A \) and \( u : A \to B \) form an adjoint pair \( f \dashv u \) if and only if there exist natural transformations \( \text{id}_B \Rightarrow uf \) and \( fu \Rightarrow \text{id}_A \) so that the triangle equality composites \( f \Rightarrow fu \Rightarrow f \) and \( u \Rightarrow uf \Rightarrow u \) are both invertible.

Proof. The unit and counit of an adjunction certainly satisfy these hypotheses. For the converse, suppose we are given natural transformations \( \eta : \text{id}_B \Rightarrow uf \) and \( \epsilon' : fu \Rightarrow \text{id}_A \) so that the triangle equality composites

\[
\phi := f \xrightarrow{f \eta} fuf \xrightarrow{\epsilon'f} f \quad \psi := u \xrightarrow{\eta u} uf u \xrightarrow{u \epsilon'} u
\]

are isomorphisms. We will construct an adjunction \( f \dashv u \) with unit \( \eta \) by modifying \( \epsilon' \) to form the counit \( \epsilon \).\(^5\) To explain the idea of the construction, note that for a fixed pair of generalized elements \( b : X \to B \) and \( a : X \to A \), pasting with \( \eta \) and with \( \epsilon' \) defines functions between the displayed sets of natural transformations:

\[
\begin{align*}
\left\{ b : X \to B \right\} & \to \left\{ a : X \to A \right\} \\
\left\{ b : X \to B \right\} & \to \left\{ a : X \to A \right\}
\end{align*}
\]

From the hypothesis that the triangle equality composites are isomorphisms, two of these functions are invertible, and then by the 2-of-6 property for isomorphisms all six maps are bijections.

Define the “corrected” counit to be the composite:

\[
\epsilon := (fu \xrightarrow{\phi^{-1}u} fu \xrightarrow{\epsilon'} \text{id}_B)
\]

\(^5\) By implementing this construction in the co-dual of the homotopy 2-category, we could alternatively take \( \epsilon' \) to be the counit at the cost of modifying \( \eta \) to form the unit; see Exercise 2.1.iii.
By “naturality of whiskering,” we have a commutative diagram

which proves that $\varepsilon f \cdot f \eta = \phi \cdot \phi^{-1} = \text{id}_f$, establishing the first of the triangle equalities.

Now by another diagram chase

we see that $(\varepsilon u \cdot \eta u) \cdot \psi = \psi$. Since $\psi$ is invertible, we may cancel to conclude that $\varepsilon u \cdot \eta u = \text{id}_u$. □

We will make repeated use of the following standard 2-categorical result, which says that any equivalence in a 2-category can be promoted to an equivalence that also defines an adjunction:

2.1.12. PROPOSITION (adjoint equivalences). Any equivalence can be promoted to an adjoint equivalence by modifying one of the 2-cells. That is, the invertible 2-cells in an equivalence can be chosen so as to satisfy the triangle equalities. Hence, if $f$ and $g$ are inverse equivalences then $f \dashv g$ and $g \dashv f$.

PROOF. Consider an equivalence comprised of functors $f : A \to B$ and $g : B \to A$ and invertible 2-cells $\alpha : f g \Rightarrow \text{id}_A$ and $\beta : g f \Rightarrow \text{id}_B$.

Since $\alpha$ and $\beta$ are both invertible, the triangle equality composites are as well, and the construction of Lemma 2.1.11 applies. □

One use of Proposition 2.1.12 is to show that adjunctions are equivalence-invariant:

2.1.13. PROPOSITION (equivalence-invariance of adjunctions). A functor $u : A \to B$ between $\infty$-categories admits a left adjoint if and only if, for any pair of equivalent $\infty$-categories $A' \simeq A$ and $B' \simeq B$, the equivalent functor $u' : A' \to B'$ admits a left adjoint.

47

Here “naturality of whiskering,” as expressed by Lemma B.1.3, asserts that the pasted composite $\varepsilon f \cdot f \eta$ can be computed as a vertical composite of two different “whiskerings” of $\eta$ and $\phi^{-1}$, in this case implying that $\phi^{-1} u f \cdot f \eta = f \eta \cdot \phi^{-1}$. 
PROOF. If \( u : A \to B \) admits a left adjoint then by composing \( f \dashv u \) with the adjoint equivalences \( A' \simeq A \) and \( B \simeq B' \) we obtain an equivalent adjunction:

\[
\begin{array}{c}
\sim & \sim & \sim & \sim \\
A' & \xleftarrow{\sim} & A & \xrightarrow{\sim} & B & \xleftarrow{\sim} & B' \\
\end{array}
\]

Conversely, if the equivalent functor \( u' : A' \simeq A \xrightarrow{u} B \simeq B' \) admits a left adjoint \( f' \) then again we obtain a composite adjunction:

\[
\begin{array}{c}
\sim & \sim & \sim & \sim \\
A & \xleftarrow{\sim} & A' & \xrightarrow{\sim} & A & \xrightarrow{\sim} & B & \xleftarrow{\sim} & B' \\
\end{array}
\]

whose right adjoint is naturally isomorphic to the original functor \( u \). By Proposition 2.1.10 the displayed left adjoint is then a left adjoint to \( u \). \( \square \)

As we shall discover, all of \( \infty \)-category theory is equivalence-invariant in this way.

For later use, we close with an example of an abstractly-defined adjunction that can be constructed for any \( \infty \)-category in any \( \infty \)-cosmos via the results proven in this section.

2.1.14. LEMMA. For any \( \infty \)-category \( A \), the “composition” functor

\[
\begin{array}{c}
\sim & \sim & \sim & \sim \\
A^2 \times A^2 & \xleftarrow{\sim} & A^2 \\
\end{array}
\]

admits left and right adjoints, which, respectively, “extend an arrow into a composable pair” by pairing it with the identities at its domain or its codomain.

PROOF. There is a dual adjunction in \( \mathbf{Cat} \) whose functors we describe using notation for simplicial operators introduced in 1.1.1; the full subcategory of \( \mathbf{Cat} \) spanned by the finite non-empty ordinals is isomorphic to \( \Delta \).

\[
\begin{array}{c}
\sim & \sim \\
\mathbf{3} & \xleftarrow{\sim} & \mathbf{2} \\
\mathbf{2} & \xrightarrow{\sim} & \mathbf{3} \\
\end{array}
\]

For any \( \infty \)-category \( A \) in an \( \infty \)-cosmos \( \mathbf{K} \), Exercise 2.1.i describes a 2-functor \( A(-) : \mathbf{Cat}^{\mathbf{op}} \to \mathbf{bK} \) carrying the adjoint triple displayed above-left to the one displayed above-right.

Now we claim there is a trivial fibration \( A^3 \Rightarrow A^2 \times_A A^2 \) constructed as follows. The pushout diagram of simplicial sets displayed below-left is carried by the simplicial cotensor \( A(-) : s\mathbf{Set}^{\mathbf{op}} \to \mathbf{K} \) to a pullback diagram displayed below-right; since the legs of the pushout square are monomorphisms, the legs of the pullback square are isofibrations.
Lemma 1.2.14 tells us that the cotensor of the inner horn inclusion \( \Lambda^1[2] \hookrightarrow \Delta[2] \cong \mathbb{3} \) with the \( \infty \)-category \( A \) defines a trivial fibration \( q: A^3 \Rightarrow A^{\Lambda^1[2]} \) and the pullback square above-left recognizes its codomain as the desired \( \infty \)-category of “composable pairs.” By Lemma 1.2.15, any section \( s \) to \( q: A^3 \Rightarrow A^2 \times_\Delta A^2 \) can be made into an equivalence inverse. By Proposition 2.1.12, these functors are both left and right adjoints. The desired adjoint triple may then be constructed as the composite adjunction:

\[
\begin{array}{ccc}
A^2 \times A^2 & \xrightarrow{q} & A^3 \\
\downarrow \downarrow & & \downarrow \downarrow \downarrow \downarrow \downarrow \\
\downarrow \downarrow & & \downarrow \downarrow \downarrow \downarrow \downarrow \\
A^2 & \xleftarrow{s} & A^3 \\
\end{array}
\]

Note that the adjoint functors of (2.1.15) commute with the “endpoint evaluation” functors to \( A \times A \). In fact, the units and counits can similarly be fibered over \( A \times A \); see Example 3.6.11.

Exercises.

2.1.i. Exercise. The aim of this exercise is to spell out the most subtle of the dual adjunction-preservation results discussed in Remark 2.1.8.

(i) Let \( A \) be an \( \infty \)-category is an \( \infty \)-cosmos \( \mathcal{K} \). Show that the simplicial cotensor restricts to define a 2-functor \( A(-): \mathcal{K} \rightarrow \mathcal{K} \).

(ii) Argue that the 2-functor of (i) restricts further along the nerve embedding to define a 2-functor \( A(-): \mathcal{K} \rightarrow \mathcal{K} \).

(iii) Conclude that for any adjunction between 1-categories as below-left there is an induced adjunction between \( \infty \)-categories as below-right:

\[
\begin{array}{ccc}
I & \xleftarrow{f} & J \\
\downarrow \downarrow & & \downarrow \downarrow \\
A^l & \xleftarrow{u^*} & A^l_0 \\
\end{array}
\]

2.1.ii. Exercise. Prove Proposition 2.1.10(ii).

2.1.iii. Exercise. Dualize the proof of Lemma 2.1.11 so that it applies in the context of Proposition 2.1.12 to show that any equivalence can be promoted into an adjoint equivalence in which the counit is part of the originally specified data.

2.1.iv. Exercise. Prove that an adjoint equivalence between \( \infty \)-categories descends to an adjoint equivalence between their homotopy categories.

2.2. Initial and Terminal Elements

Employing the tactic used in Definition 1.4.12 to define the homotopy category of an \( \infty \)-category, we use the terminal \( \infty \)-category 1 to probe inside an \( \infty \)-category \( A \). An object \( a \) in the homotopy category \( hA \) is defined to be a map of \( \infty \)-categories \( a: 1 \rightarrow A \). To avoid the proliferation of the term “objects,” and in deference to Lawvere’s notion of (generalized) elements [71], we refer to maps \( a: 1 \rightarrow A \) as elements\(^7\) of the \( \infty \)-category \( A \) henceforth. This terminology will help us keep track of

\(^7\)An **generalized element** of \( A \) is a functor \( f: X \rightarrow A \). By the Yoneda lemma, an \( \infty \)-category is determined by its generalized elements.
the “category level” under discussion: elements \( a \) live inside \( \infty \)-categories \( A \), which are the objects of \( \infty \)-cosmoi \( \mathcal{K} \)—which themselves define “infinite-dimensional categories,” albeit of a different sort.

Before introducing limits and colimits of general \( \infty \)-category valued diagrams, we warm up by defining initial and terminal elements in an \( \infty \)-category \( A \).

### 2.2.1. Definition (initial/terminal element)

An **initial element** in an \( \infty \)-category \( A \) is a left adjoint to the unique functor \( !: A \to 1 \), as displayed below-left, while a **terminal element** in an \( \infty \)-category \( A \) is a right adjoint, as displayed below-right.

Let us unpack the definition of an initial element; dual remarks apply to terminal elements.

### 2.2.2. Lemma (the minimal data required to present an initial element)

To define an initial element in \( A \), it suffices to specify

- an element \( i: 1 \to A \)
- a natural transformation from the constant functor at \( i \) to the identity functor

\[
\begin{array}{ccc}
A & \xrightarrow{!} & 1 \\
\downarrow{e} & \parallel & \downarrow{i} \\
A & \xrightarrow{i} & A
\end{array}
\]

so that the component \( e_i : i \Rightarrow i \), an arrow from \( i \) to \( i \) in \( hA \), is the identity.

**Proof.** Proposition 1.4.5, whose proof starts in the paragraph before its statement, demonstrates that the \( \infty \)-category \( 1 \in \mathcal{K} \) is terminal in the homotopy 2-category \( h \mathcal{K} \). The 1-dimensional aspect of this universal property implies that \( i \) defines a section of the unique map \( A \to 1 \), while the 2-dimensional aspect asserts that there exist no non-identity 2-cells with codomain 1. In particular, the unit of the adjunction \( i \dashv ! \) is necessarily an identity and one of the triangle equalities comes for free. The data enumerated above is what remains of Definition 2.1.1 in this setting.

Put more concisely, an initial element \( i \) defines a **left adjoint right inverse** to the functor \( !: A \to 1 \). Such adjunctions are studied more systematically in §B.4. In fact, it suffices to assume that the counit component \( e_i \) is an isomorphism, for this in fact implies already that \( ei \) is the identity; see Exercise 2.2.i.

### 2.2.3. Lemma (uniqueness)

Any two initial elements in an \( \infty \)-category \( A \) are isomorphic in \( hA \) and any element of \( hA \) that is isomorphic to an initial element is initial.

**Proof.** By Proposition 2.1.10, any two left adjoints \( i \) and \( i' \) to the functor \( !: A \to 1 \) are naturally isomorphic, and any \( a: 1 \to A \) that is isomorphic to a left adjoint to \( !: A \to 1 \) is itself a left adjoint. A natural isomorphism between a pair of functors \( i, i': 1 \to A \) gives exactly the data of an isomorphism \( i \cong i' \) between the corresponding elements of the homotopy category \( hA \).

### 2.2.4. Remark (representable initiality)

Applying the 2-functor \( \text{Fun}(X, -): h \mathcal{K} \to h\text{QCat} \) to an initial element \( i: 1 \to A \) or terminal element \( t: 1 \to A \) of an \( \infty \)-category \( A \in \mathcal{K} \) yields adjunctions

\[
\begin{array}{ccc}
\mathbb{1} & \cong & \text{Fun}(X, 1) \\
\downarrow{!} & & \downarrow{!} \\
\text{Fun}(X, A) & \cong & \mathbb{1} \\
\end{array}
\]

\[
\begin{array}{ccc}
\mathbb{1} & \cong & \text{Fun}(X, 1) \\
\downarrow{t} & & \downarrow{t} \\
\text{Fun}(X, A) & \cong & \mathbb{1}
\end{array}
\]

50
Via the isomorphisms $\text{Fun}(X, 1) \cong 1$ that express the universal property of the terminal $\infty$-category $1$, we see that the constant functor at an initial or terminal element

$$X \xrightarrow{i} 1 \xrightarrow{i} A$$

or

$$X \xrightarrow{i} 1 \xrightarrow{\sim} A$$

defines an initial or terminal element, respectively, of the functor space $\text{Fun}(X, A)$. This observation can be summarized by saying that initial or terminal elements are representably initial or terminal at the level of the $\infty$-cosmos.

Conversely, if $i: 1 \to A$ is representability initial, then $i$ defines an initial element of $A$. This is most easily seen by passing to the homotopy 2-category, where we can show that an initial element $i: 1 \to A$ is initial among all generalized elements $f: X \to A$ in the following precise sense.

2.2.5. Lema. An element $i: 1 \to A$ is initial if and only if for all $f: X \to A$ there exists a unique 2-cell with boundary

$$X \xrightarrow{!} 1 \xrightarrow{i} A$$

Proof. If $i: 1 \to A$ is initial, then the adjunction of Definition 2.2.1 is preserved by the 2-functor $h\text{Fun}(X, -): h\mathcal{K} \to \text{Cat}$, defining an adjunction

$$1 \cong h\text{Fun}(X, 1) \perp h\text{Fun}(X, A)$$

Via the isomorphism $h\text{Fun}(X, 1) \cong 1$, this adjunction proves that the constant functor $i!: X \to A$ is initial in the category $h\text{Fun}(X, A)$ and thus has the universal property of the statement.

Conversely, if $i: 1 \to A$ satisfies the universal property of the statement, applying this to the generic element of $A$ (the identity map $\text{id}_A: A \to A$) easily produces the data of Lemma 2.2.2. □

Lemma 2.2.5 says that initial elements are representably initial in the homotopy 2-category. Specializing the generalized elements to ordinary elements, we see that initial and terminal elements in $A$ respectively define initial and terminal elements in its homotopy category:

$$1 \xleftarrow{i} hA$$

(2.2.6)

Continuing the theme of the equivalence-invariance of $\infty$-categorical notions:

2.2.7. Lema. If $A$ has an initial element and $A \simeq A'$ then $A'$ has an initial element and these elements are preserved up to isomorphism by the equivalences.

Proof. By Proposition 2.1.12, the equivalence $A \simeq A'$ can be promoted to an adjoint equivalence, which can immediately be composed with the adjunction characterizing an initial element $i$ of $A$:

$$1 \xleftarrow{i} A \xleftarrow{\sim} A'$$
The composite adjunction provided by Proposition 2.1.9 proves that the image of \( i \) defines an initial element of \( A' \), which by construction is preserved by the equivalence \( A \cong A' \).

To see that the equivalence \( A' \cong A \) also preserves initial elements, we can use the invertible 2-cells of the equivalence to see that \( i \) is isomorphic to the image of \( i \) in \( A' \). In case the initial objects in mind are not the ones being considered here, we can appeal to the uniqueness of initial elements proven in Lemma 2.2.3.

We now turn to the general theory of limits and colimits of diagrams valued in an \( \infty \)-category. The theory of initial elements previews this material well since in fact an initial element can be understood as an example of both notions: an initial element is the colimit of the empty diagram and also the limit of the diagram encoded by the identity functor, as we explain in Example 2.3.9.

**Exercises.**

2.2.i. **Exercise (B.4.2).** Show that if given

- an element \( i : 1 \to A \) and
- a natural transformation \( 1 \\downarrow \epsilon \Rightarrow i \\downarrow ! \)

so that the component \( \epsilon_i : i \Rightarrow i \) is an isomorphism in \( hA \), then in fact \( \epsilon_i = \text{id}_i \). This weakens the minimal data required to present an initial element in the statement of Lemma 2.2.2.

2.2.ii. **Exercise.** Use Lemma 2.2.5 to show that a representably initial element, as described in Remark 2.2.4, necessarily defines an initial element in \( A \).

2.2.iii. **Exercise.** Prove that initial elements are preserved by left adjoints and terminal elements are preserved by right adjoints.

### 2.3. Limits and Colimits

Our aim is now to introduce limits and colimits of diagram valued inside an \( \infty \)-category \( A \) in some \( \infty \)-cosmos. We will consider two varieties of diagrams:

- In a generic \( \infty \)-cosmos \( \mathcal{K} \), we shall consider diagrams indexed by a simplicial set \( J \) and valued in an \( \infty \)-category \( A \).
- In a cartesian closed \( \infty \)-cosmos \( \mathcal{K} \), we shall also consider diagrams indexed by an \( \infty \)-category \( J \) and valued in an \( \infty \)-category \( A \).\(^8\)

**2.3.1. Definition (diagram \( \infty \)-category).** For a simplicial set \( J \) — or possibly, in the case of a cartesian closed \( \infty \)-cosmos, an \( \infty \)-category \( J \) — and an \( \infty \)-category \( A \), we refer to \( A^J \) as the \( \infty \)-category of \( J \)-shaped diagrams in \( A \). A diagram of shape \( J \) in \( A \) is an element \( d : 1 \to A^J \).\(^9\)

---

\(^8\)For the \( \infty \)-cosmoi of \((\infty,1)\)-categories of Example 1.2.24, there is no essential difference between these notions: in \( \text{QCat} \) they are tautologically the same, and in all biequivalent \( \infty \)-cosmoi the \( \infty \)-category of \( J \)-shaped diagrams indexed by an \( \infty \)-category \( J \) is equivalent to the \( \infty \)-category of \( J \)-shaped diagrams indexed by its underlying quasi-category, regarded as a simplicial set; see Proposition 10.3.5.

\(^9\)When \( A^J \) is the exponential of a cartesian closed \( \infty \)-cosmos, diagrams stand in bijection with functors \( d : J \to A \).
Both constructions of the \(\infty\)-category of diagrams define simplicial bifunctors
\[
s\mathsf{Set}^{\text{op}} \times \mathcal{K} \longrightarrow \mathcal{K}
\]
\[
\mathcal{K}^{\text{op}} \times \mathcal{K} \longrightarrow \mathcal{K}
\]
\[
(J, A) \longmapsto A^J
\]

In either indexing context, there is a terminal object \(1\) with the property that \(A^1 \cong A\) for any \(\infty\)-category \(A\). Restriction along the unique map \(! : J \to 1\), induces the constant diagram functor \(\Delta : A \to A^J\).

We are deliberately conflating the notation for \(\infty\)-categories of diagrams indexed by a simplicial set or by another \(\infty\)-category because all of the results we will prove in Part I about the former case will also apply to the latter. For economy of language, we refer only to simplicial set indexed diagrams for the remainder of this section.

2.3.2. Definition (limit and colimit functor). An \(\infty\)-category \(A\) admits all colimits of shape \(J\) if the constant diagram functor \(\Delta : A \to A^J\) admits a left adjoint, while \(A\) admits all limits of shape \(J\) if the constant diagram functor admits a right adjoint:

\[
\begin{array}{ccc}
\text{colim} & \cong & A^J \\
\Delta & \cong & \Delta \\
\text{lim} & \cong & A
\end{array}
\]

In the \(\infty\)-cosmos of categories, Definition 2.3.2 reduces to the classically-defined limit and colimit functors, but in a general \(\infty\)-category limits and colimits should be thought of as analogous to the classical notions of “homotopy limits” and “homotopy colimits.” In certain cases, this correspondence can be made precise. Every quasi-category is equivalent to the homotopy coherent nerve of a Kan complex enriched category \([107, 7.2.2]\), and in this context it is known that homotopy limit or homotopy colimit cones in the Kan complex enriched category correspond exactly to limit or colimit cones in the homotopy coherent nerve; see Lurie’s \([74, 4.2.4.1]\) or \([109, 6.1.4, 6.2.7]\). In the \(\infty\)-categorical context, no stricter notion of limit or colimit is available, so the “homotopy” qualifier is typically dropped.

2.3.3. Warning. Limits or colimits of set-indexed diagrams — the case where the indexing shape is a coproduct of the terminal object \(1\) indexed by a set \(J\) — are called products or coproducts, respectively. In this case the \(\infty\)-category of diagrams itself decomposes as a product \(A^J \cong \prod_J A\). Since the functor

\[
\begin{array}{ccc}
h\mathcal{K} & \xrightarrow{h\text{Fun}(1,-)} & \text{Cat} \\
A & \longmapsto & hA
\end{array}
\]

that carries an \(\infty\)-category to its homotopy category preserves products, when \(J\) is a set there is a chain of isomorphisms

\[
h(A^J) \cong h(\prod_J A) \cong \prod_J hA \cong (hA)^J
\]
Thus, in this special case the adjunctions of Definition 2.3.2 that define products or coproducts in an ∞-category descend to the adjunctions that define products or coproducts in its homotopy category:

\[
\text{colim} \xrightarrow{\sim} (hA)^l \cong h(A^l) \xleftarrow{\Delta} hA \xrightarrow{\lim}
\]

This remains true in the case \( J = \emptyset \), explaining the observation made in (2.2.6).

However, this argument does not extend to more general limit or colimit notions, and such ∞-categorical limits or colimits do not typically descend to limits or colimits in the homotopy category.¹⁰ In §3.2, we observe that the homotopy category construction fails to preserve more complicated cotensors, even in the relatively simple case of \( J = 2 \).

The problem with Definition 2.3.2 is that it is insufficiently general: many ∞-categories will have certain, but not all, limits of diagrams of a particular indexing shape. So it would be desirable to re-express Definition 2.3.2 in a form that allows us to define the limit of a single diagram \( d: 1 \to A^l \) or of a family of diagrams. To achieve this, we make use of the following 2-categorical notion that op-dualizes the more familiar absolute (Kan) extension diagrams.

2.3.4. Definition (absolute lifting diagram). Given a cospan \( C \xrightarrow{g} A \leftarrow f B \) in a 2-category, an absolute left lifting of \( g \) through \( f \) is given by a 1-cell \( \ell \) and 2-cell \( \lambda \) as displayed below-left:

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A \\
\downarrow \ell & & \downarrow \lambda \\
B & \xrightarrow{f} & A
\end{array}
\]

so that any 2-cell as displayed above-center factors uniquely through \( (\ell, \lambda) \) as displayed above-right.

Dually, an absolute right lifting of \( g \) through \( f \) is given by a 1-cell \( r \) and 2-cell \( \rho \) as displayed below-left:

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A \\
\downarrow r & & \downarrow \rho \\
B & \xrightarrow{f} & A
\end{array}
\]

so that any 2-cell as displayed above-center factors uniquely through \( (r, \rho) \) as displayed above-right.

The adjectives “left” and “right” refer to the handedness of the adjointness of these constructions: when these exist, left and right liftings respectively define left and right adjoints to the composition functor \( f_*: \text{hFun}(C, B) \to \text{hFun}(C, A) \), with the 2-cells defining the components of the unit and counit of these adjunctions, respectively, at the object \( g \). The adjective “absolute” refers to the following stability property.

¹⁰This sort of behavior is expected in abstract homotopy theory: homotopy limits and colimits are not generally limits or colimits in the homotopy category.
2.3.5. **Lemma.** Absolute left or right lifting diagrams are stable under restriction of their domain object: if \((\ell, \lambda)\) defines an absolute left lifting of \(g\) through \(f\), then for any \(c: X \to C\), the restricted diagram \((\ell c, \lambda c)\) defines an absolute left lifting of \(g c\) through \(f\).

\[
\begin{array}{ccc}
X & \xrightarrow{\ell} & C \\
\downarrow{c} & \searrow{\lambda} & \searrow{g} \\
\downarrow{f} & & \downarrow{A}
\end{array}
\]

**Proof.** Exercise 2.3.ii.

Units and counits of adjunctions provide important examples of absolute left and right lifting diagrams respectively:

2.3.6. **Lemma.** A 2-cell \(\eta: \text{id}_B \Rightarrow u f\) defines the unit of an adjunction \(f \dashv u\) if and only if \((f, \eta)\) defines an absolute left lifting diagram, displayed below-left.

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow{u} & & \downarrow{u} \\
B & \xrightarrow{\eta} & A
\end{array}
\]

Dually a 2-cell \(\epsilon: u \Rightarrow \text{id}_A\) defines the counit of an adjunction if and only if \((u, \epsilon)\) defines an absolute right lifting diagram, displayed above-right.

**Proof.** The universal property of the absolute right lifting diagram

\[
\begin{array}{ccc}
X & \xrightarrow{b} & B \\
\downarrow{a} & \downarrow{\eta a} & \downarrow{f} \\
A & \xrightarrow{\epsilon} & A
\end{array}
\]

asserts that every natural transformation \(\alpha: f b \Rightarrow a\) has a unique transpose \(\beta: b \Rightarrow u a\) across the adjunction between the hom-categories of the homotopy 2-category:

\[
\begin{array}{ccc}
hFun(X, B) & \xrightarrow{f_*} & hFun(X, A) \\
\downarrow{u_*} & & \downarrow{u_*}
\end{array}
\]

Thus if \(f \dashv u\) with counit \(\epsilon\), Proposition 2.1.7(ii) supplies this induced adjunction and \((u, \epsilon)\) defines an absolute right lifting if \(\text{id}_A\) through \(f\).

Conversely, the unit and triangle equalities of an adjunction can extracted from the universal property of the absolute right lifting diagram. The details are left as Exercise 2.3.iii.

In particular, the unit and counit of the adjunctions \(\text{colim} \dashv \Delta \dashv \text{lim}\) of Definition 2.3.2 define absolute left and right lifting diagrams:

\[
\begin{array}{ccc}
\text{colim} & \xrightarrow{\eta} & A \\
\downarrow{\Delta} & & \downarrow{\Delta} \\
\text{colim} & \xrightarrow{\eta} & A
\end{array}
\]

\[
\begin{array}{ccc}
\text{lim} & \xleftarrow{\epsilon} & A \\
\downarrow{\Delta} & & \downarrow{\Delta} \\
\text{lim} & \xleftarrow{\epsilon} & A
\end{array}
\]
By Lemma 2.3.5, these universal properties are retained upon restricting to any subobject of the ∞-category of diagrams. This motivates the following definition:

2.3.7. **Definition** (limit and colimit). A **colimit** of a family of diagrams \( d: D \to A^I \) indexed by \( I \) in an ∞-category \( A \) is given by an absolute left lifting diagram

\[
\begin{array}{ccc}
A & \xrightarrow{\text{colim}} & \Delta \\
\downarrow & & \downarrow \\
D & \xrightarrow{d} & A^I
\end{array}
\]

comprised of a **colimit functor** \( \text{colim}: D \to A \) and a **colimit cone** \( \eta: d \Rightarrow \Delta \text{colim} \).

Dually, a **limit** of a family of diagrams \( d: D \to A^I \) indexed by \( I \) in an ∞-category \( A \) is given by an absolute right lifting diagram

\[
\begin{array}{ccc}
A & \xleftarrow{\lim} & \Delta \\
\downarrow & & \downarrow \\
D & \xrightarrow{d} & A^I
\end{array}
\]

comprised of a **limit functor** \( \lim: D \to A \) and a **limit cone** \( \epsilon: \Delta \lim \Rightarrow d \).

2.3.8. **Remark.** If \( A \) has all limits of shape \( I \), then Lemma 2.3.5 implies that any family of diagrams \( d: D \to A^I \) has a limit, defined by evaluating the limit functor \( \lim: A^I \to A \) at \( d \), i.e., by the composite \( \lim d \). In the ∞-cosmoi of \((\infty, 1)\)-categories, Corollary 12.2.10 shows that if every diagram \( d: 1 \to A^I \) has a limit, then \( A \) has all \( I \)-indexed limits. This is because the terminal \((\infty, 1)\)-category generates such ∞-cosmoi in a suitable sense, though this generation property does not hold for all ∞-cosmoi.

2.3.9. **Example.** An initial element \( i: 1 \to A \) can be regarded as both a colimit of the empty diagram and as a limit of the identity functor, as we now explain. The ∞-category \( A^\emptyset = 1 \) of empty diagrams in \( A \) is terminal, so in this context the constant diagram functor reduces to \( !: A \to 1 \). To show that initial elements are colimits in the sense of Definition 2.3.7, we must verify that an initial element defines an absolute left lifting diagram, as displayed below-left, whose 2-cell is the identity:

Since the ∞-category \( 1 \) is 2-terminal, there is a unique 2-cell \( \chi \) inhabiting the central square above, namely the identity. Thus, the universal property of the absolute left lifting diagram asserts the existence of a unique 2-cell \( \zeta: i! \Rightarrow f \) for any \( f: X \to A \), exactly as provided by Lemma 2.2.5.

In a cartesian closed ∞-cosmos, we may also use Definition 2.3.7 to characterize an initial object as a limit for the identity functor \( \text{id}_A: A \to A \). The counit \( \epsilon: i! \Rightarrow \text{id}_A \) of the adjunction \( i \dashv ! \) transposes across the 2-adjunction \( A \times - \to (-)^A \) of Proposition 1.4.5 to define the limit cone displayed below-left:
The universal property displayed above-right is easiest to verify by transposing across $A \times - \to (-)^A$, where we must show that

$$
\begin{array}{c}
\begin{array}{c}
X \\
X \times A
\end{array}
\xrightarrow{f} \\
1 \to A
\end{array}
= 
\begin{array}{c}
\begin{array}{c}
\pi_X \\
\pi_A
\end{array}
\xrightarrow{\pi_X} \\
\xrightarrow{\pi_A}
\end{array}
\begin{array}{c}
\begin{array}{c}
X \\
X \times A
\end{array}
\xrightarrow{f} \\
1 \to A
\end{array}
\end{array}
\tag{2.3.10}
$$

Observe that when we restrict the right-hand side of (2.3.10) along the functor $\text{id}_X \times i: X \cong X \times 1 \to X \times A$ we recover the 2-cell $\zeta$, since $e i = \text{id}_i$. This tells us that given $\chi$, we must necessarily define the 2-cell $\zeta: f \Rightarrow i!$ to be the restriction of $\hat{\chi}$ along the functor $\text{id}_X \times i$.

From this definition of $\zeta$ and the 2-functoriality of the cartesian product—which tells us that $\epsilon \pi_A = \pi_A(X \times e)$—we have

$$
\begin{array}{c}
\begin{array}{c}
\pi_X \\
\pi_A
\end{array}
\xrightarrow{\pi_X} \\
\xrightarrow{\pi_A}
\end{array}
\begin{array}{c}
\begin{array}{c}
X \\
X \times A
\end{array}
\xrightarrow{f} \\
1 \to A
\end{array}
= 
\begin{array}{c}
\begin{array}{c}
\pi_X \\
\pi_A
\end{array}
\xrightarrow{\pi_X} \\
\xrightarrow{\pi_A}
\end{array}
\begin{array}{c}
\begin{array}{c}
X \times 1 \\
X \times A
\end{array}
\xrightarrow{id_X \times i} \\
\xrightarrow{\pi_X \times e}
\end{array}
\begin{array}{c}
\begin{array}{c}
X \\
X \times A
\end{array}
\xrightarrow{f} \\
1 \to A
\end{array}
\end{array}
$$

By “naturality of whiskering,” explained in Lemma B.1.3, the right-hand pasted composite can be computed as the vertical composite of $\pi_X(X \times e)$ followed by $\hat{\chi}$, but $\pi_X(X \times e)$ is the identity 2-cell, so this composite is just $\hat{\chi}$. This verifies the desired pasting identity (2.3.10). This result is extended to non-cartesian closed $\infty$-cosmoi in Proposition 9.5.4.

A few limits and colimits in $\infty$-categories exist for formal reasons. For example, an abstract 2-categorical lemma enables general proof of a classical result from homotopy theory that computes the colimits, typically called geometric realizations, of “split” simplicial objects. Before proving this, we introduce the indexing shapes involved.

2.3.11. DEFINITION (split augmented (co)simplicial object). Recall $\Delta$ is the simplex category of finite non-empty ordinals and order-preserving maps introduced in 1.1.1. It defines a full subcategory of the category $\Delta_+$ of finite ordinals and order-preserving maps, which freely appends the empty ordinal “$[-1]$” as an initial object. The category $\Delta_+$ in turn defines a wide subcategory of a category $\Delta_\perp$, which adds an “extra” degeneracy $\sigma^{-1}: [n + 1] \to [n]$ between each pair of consecutive ordinals, including $\sigma^{-1}: [0] \to [-1]$. The category $\Delta_+$ also defines a wide subcategory of a category $\Delta_\top$, which adds an “extra” degeneracy $\sigma^{n+1}: [n + 1] \to [n]$ on the other side between each pair of consecutive ordinals, including $\sigma^0: [0] \to [-1]$. The categories $\Delta_\perp$ and $\Delta_\top$ can be described in another way: there are faithful embeddings of these categories into $\Delta$ that act on objects by $[n] \to [n + 1]$ and identify $\Delta_\perp$ and $\Delta_\top$ with the subcategories of finite non-empty ordinals and order-preserving maps that preserve the bottom and top elements in each ordinal respectively. This explains our notation.

Diagrams indexed by $\Delta \subset \Delta_+ \subset \Delta_\perp, \Delta_\top$ are respectively called cosimplicial objects, coaugmented cosimplicial objects, and split coaugmented cosimplicial objects (in the case of either $\Delta_\perp$ or $\Delta_\top$), if they are covariant, and simplicial objects, augmented simplicial objects, and split augmented simplicial...
objects, if they are contravariant. When it is useful to disambiguate between $\Delta_\perp$ and $\Delta_\top$ we refer to the former category as a “bottom splitting” and the latter category as a “top splitting,” but this terminology is not standard.

A simplicial object $d : 1 \to A^{\Delta^\text{op}}$ in an $\infty$-category $A$ admits an augmentation or admits a splitting, if it lifts along the restriction functors

\[
\begin{array}{ccc}
\Delta & \xrightarrow{\eta} & \Delta_+ \\
\downarrow & & \downarrow \\
[1] & \xleftarrow{[1]} & \Delta^{\text{op}} \\
\end{array}
\]

where in the case of a top splitting, $\Delta_\perp$ is replaced by $\Delta_\top$. The family of simplicial objects admitting an augmentation and splitting is then represented by the generalized element $A^{\Delta_\perp^{\text{op}}} \to A^{\Delta_\top^{\text{op}}}$. The following proposition proves that for any simplicial object admitting a splitting, the augmentation defines the colimit cone; dual results apply to limits of split cosimplicial objects. The limit and colimit cones are defined by cotensoring with the unique natural transformation

\[
(2.3.12)
\]

that exists because $[-1] : [1] \to \Delta_\perp$ is initial; see Lemma 2.2.5.

2.3.13. PROPOSITION (totalization/geometric realization). Let $A$ be any $\infty$-category. Every cosimplicial object in $A$ that admits a coaugmentation and a splitting has a limit, with the coaugmentation defining the limit cone. Dually, every simplicial object in $A$ that admits an augmentation and a splitting has a colimit, with the augmentation defining the colimit cone. That is, there exist absolute right and left lifting diagrams

\[
\begin{array}{ccc}
A & \xleftarrow{\text{ev}[1]} & A^\perp \\
\downarrow & & \downarrow \\
\Delta & \xleftarrow{\eta_{A^\perp}} & \Delta_+ \\
\end{array}
\]

\[
\begin{array}{ccc}
A & \xrightarrow{\text{ev}[1]} & A^\top \\
\downarrow & & \downarrow \\
\Delta & \xrightarrow{\eta_{A^\top}} & \Delta_+ \\
\end{array}
\]

\[
\begin{array}{ccc}
A^{\Delta^\text{op}} & \xrightarrow{\text{ev}[1]} & A^{\Delta_\perp^\text{op}} \\
\downarrow & & \downarrow \\
\Delta & \xrightarrow{\eta_{A^{\Delta_\top^\text{op}}}} & \Delta_+ \\
\end{array}
\]

\[
\begin{array}{ccc}
A^{\Delta^\text{op}} & \xrightarrow{\text{ev}[1]} & A^{\Delta_\top^\text{op}} \\
\downarrow & & \downarrow \\
\Delta & \xrightarrow{\eta_{A^{\Delta_\top^\text{op}}}} & \Delta_+ \\
\end{array}
\]

in which the 2-cells are obtained as restrictions of the cotensor of the 2-cell (2.3.12) with $A$. Moreover, such limits and colimits are absolute, preserved by any functor $f : A \to B$ of $\infty$-categories.

PROOF. By Example B.5.2, the inclusion $\Delta \hookrightarrow \Delta_\perp$ admits a right adjoint, which can automatically be regarded as an adjunction “over $[1]$” since $[1]$ is 2-terminal. The initial element $[-1] \in \Delta_+ \subset \Delta_\perp$
defines a left adjoint to the constant functor:

\[ \Delta \leftrightarrow \Delta_+ \leftrightarrow \Delta_\perp \]

and the counit of this adjunction restricts along the inclusions \( \Delta \subset \Delta_+ \subset \Delta_\perp \) to the 2-cell (2.3.12). These adjunctions are preserved by the 2-functor \( A^{(-)} : \text{Cat}^{\text{op}} \to \mathcal{K} \), yielding a diagram

\[ A \Delta_\perp \xrightarrow{\text{res}} A \Delta_+ \xrightarrow{\text{res}} A \Delta \]

By Lemma B.5.1 these adjunctions witness the fact that evaluation at \([-1]\) and the 2-cell from (2.3.12) define an absolute right lifting of the canonical restriction functor \( A^{\perp} \to A^{\Delta} \) through the constant diagram functor, as claimed. The colimit case is proven similarly by applying the composite 2-functor

\[ \text{Cat}^{\text{coop}} \xrightarrow{(-)^{\text{op}}} \text{Cat}^{\text{op}} \xrightarrow{A^{(-)}} \mathcal{K} \]

A similar argument, starting from Example B.5.3, constructs the absolute lifting diagrams from the top splitting.

Finally, by the 2-functoriality of the simplicial cotensor, any \( f : A \to B \) commutes with the 2-cells defined by cotensoring with \( \nu \) or its opposite.

\[ A \Delta_\perp \xrightarrow{\text{res}} A \Delta_+ \xrightarrow{\text{res}} A \Delta \]

Since the right-hand composite is an absolute right lifting diagram, so is the left-hand composite, which says that \( f : A \to B \) preserves the totalization of any split coaugmented cosimplicial object in \( A \). □

**Exercises.**

2.3.i. Exercise. Prove that if an \( \infty \)-category \( A \) has binary products then it also has ternary products (and in fact \( n \)-ary products for all \( n \geq 1 \)). Show further that the ternary product functor can be defined from the binary product functor \( - \times - : A \times A \to A \) either as the composite \( (- \times -) \times - \) or as the composite \( - \times (- \times -) \); that is, show that these composites are naturally isomorphic and both satisfy the universal property that characterizes ternary products.

2.3.ii. Exercise. Prove Lemma 2.3.5.

2.3.iii. Exercise. Re-prove the forwards implication of Lemma 2.3.6 by following your nose through a pasting diagram calculation to prove the converse similarly.
2.3.iv. Exercise. Let $\mathcal{C}$ be the category defined by gluing two arrows along their codomain. Diagrams of shape $\mathcal{C}$ are called cospans. Consider either of the surjective functors $k: \mathcal{C} \to \mathbf{2}$ that send one of these arrows to an identity. Show that for any $\infty$-category $A$, the corresponding functor $A^k: A^\mathbf{2} \to A^\mathcal{C}$ admits an absolute right lifting through the constant diagram functor $\Delta: A \to A^\mathcal{C}$. That is, show that any $\infty$-category admits pullbacks of cospans in which one of the two arrows is an identity.

2.3.v. Exercise (3.5.6). Show that for any functor $k: A \to B$, the identity

$$
\begin{array}{ccc}
A & \xrightarrow{k} & B \\
\downarrow & & \downarrow \\
A & \xrightarrow{k} & B \\
\end{array}
$$

defines an absolute right lifting of $k$ through itself if and only if the identity defines an absolute left lifting of $k$ through itself by proving that each of these conditions is equivalent to the assertion that for any $\infty$-category $X$ the induced functor

$$k_*: \text{hFun}(X, A) \to \text{hFun}(X, B)$$

is fully-faithful. A fourth equivalent characterization of what it means for a functor between $\infty$-categories to be fully faithful will appear in Corollary 3.5.6.

2.3.vi. Exercise. Show that diagrams that are isomorphic to absolute right lifting diagrams are themselves absolute right lifting. That is, suppose given an absolute right lifting diagram and natural isomorphisms

$$
\begin{array}{ccc}
C & \xrightarrow{r} & B \\
\downarrow \cong \downarrow \cong & & \downarrow \cong \downarrow \cong \\
C & \xrightarrow{g} & A
\end{array}
$$

Then the pasted composite

$$
\begin{array}{ccc}
C & \xrightarrow{r'} & B \\
\downarrow \cong \downarrow \cong & & \downarrow \cong \downarrow \cong \\
C & \xrightarrow{g'} & A
\end{array}
$$

is an absolute right lifting diagram. Consequently, any element that is isomorphic to a limit of a diagram is itself a limit of that diagram.

2.4. Preservation of Limits and Colimits

A functor $f: A \to B$ preserves limits if the image of a limit cone in $A$ also defines a limit cone in $B$. In the other direction, a functor $f: A \to B$ reflects limits if a cone in $A$ that defines a limit cone in $B$ is also a limit cone in $A$. A functor $f: A \to B$ creates limits if whenever a diagram in $A$ admits a limit cone in $B$, then there must exist a limit cone in $A$ whose image under $f$ is isomorphic to the given limit cone in $B$.

Famously, right adjoint functors preserve limits and left adjoints preserve colimits. Our aim in this section is to prove this in the $\infty$-categorical context and exhibit the first examples of initial and
final functors, in the sense introduced in Definition 2.4.6 below. We conclude with a result about the reflection of limits whose proof relies in a crucial way on a result—that cosmological functors preserve absolute lifting diagrams—the pursuit of which will motivate the work to be done in Chapter 3.

The commutativity of right adjoints and limits is very easily established in the case where the $\infty$-categories in question admit all limits of a given shape: under these hypotheses, the limit functor is right adjoint to the constant diagram functor, which commutes with all functors between the base $\infty$-categories. Since the left adjoints commute, the uniqueness of adjoints (Proposition 2.1.10) implies that the right adjoints do as well. This outline gives a hint for Exercise 2.4.i.

A slightly more delicate argument is needed in the general case, involving, say, the preservation of a single limit diagram without a priori assuming that any other limits exist. This follows easily from a general lemma about composition and cancelation of absolute lifting diagrams:

2.4.1. Lemma (composition and cancelation of absolute lifting diagrams). Suppose $(r, \rho)$ defines an absolute right lifting of $h$ through $f$:

```
\begin{array}{ccc}
  C & \xrightarrow{s} & B \\
  \downarrow{\sigma} & & \downarrow{f} \\
  D & \xleftarrow{r} & A
\end{array}
```

Then $(s, \sigma)$ defines an absolute right lifting of $r$ through $g$ if and only if $(s, \rho \cdot f \sigma)$ defines an absolute right lifting of $h$ through $f g$.

**Proof.** Exercise 2.4.ii. \[\square\]

2.4.2. Theorem (RAPL/LAPC). Right adjoints preserve limits and left adjoints preserve colimits.

The usual argument that right adjoints preserve limits proceeds like this: a cone over a $J$-shaped diagram in the image of $u$ transposes across the adjunction $f^l \dashv u^l$ to a cone over the original diagram, which factors through the designated limit cone. This factorization transposes across the adjunction $f \dashv u$ to define the sought-for unique factorization through the image of the limit cone. An $\infty$-categorical proof along these lines can be given as well and is left as Exercise 2.4.iii.$^{11}$ Here we present a slicker packaging of the standard argument. The use of absolute lifting diagrams to express the universal properties of limits and colimits (Definition 2.3.7) and adjoint transposition (Lemma 2.3.6) allows us to economize on the usual proof by suppressing consideration of a generic test cone that must be shown to uniquely factor through the limit cone.

**Proof.** We prove that right adjoints preserve limits. By taking co-duals the same argument demonstrates that left adjoints preserve colimits.

Suppose $u: A \to B$ admits a left adjoint $f: B \to A$ with unit $\eta: i_B \Rightarrow uf$ and counit $\epsilon: fu \Rightarrow id_A$. Our aim is to show that any absolute right lifting diagram as displayed below-left is carried to an

---

$^{11}$Theorem 9.6.8 extends this result to weighted limits and weighted colimits with a proof along these lines.
absolute right lifting diagram as displayed below-right:

\[
\begin{array}{ccc}
\text{lim} & A \\
\downarrow & \downarrow \Delta \\
D & \to & A^l
\end{array}
\quad \quad \quad
\begin{array}{ccc}
\text{lim} & A & \to B \\
\downarrow & \downarrow \Delta \\
D & \to & A^l
\end{array}
\]

By Proposition 2.1.7, the cotensor \((-)^l : b\mathcal{K} \to b\mathcal{K}\) carries the adjunction \(f \dashv u\) to an adjunction \(f^l \dashv u^l\) with unit \(\eta^l\) and counit \(\epsilon^l\). In particular, by Lemma 2.3.6, \((u^l, \epsilon^l)\) defines an absolute right lifting of the identity through \(f^l\), which is then preserved by restriction along the functor \(d\). Thus, by Lemma 2.4.1, the diagram on the right of (2.4.3) is an absolute right lifting diagram if and only if the pasted composite displayed below-left defines an absolute right lifting diagram:

\[
\begin{array}{ccc}
\text{lim} & A & \to B \\
\downarrow & \downarrow \Delta \\
D & \to & A^l & \to B^l
\end{array}
\quad = \quad
\begin{array}{ccc}
\text{lim} & A & \to A \\
\downarrow & \downarrow \Delta \\
D & \to & A^l
\end{array}
\]

As noted in the proof of Lemma 2.3.6, pasting the 2-cell on the right of (2.4.3) with the counit in this way amounts to transposing the cone under \(u\) across the adjunction \(f^l \dashv u^l\).

We’ll now argue that this transposed cone above-left factors through the limit cone \((\text{lim}, \rho)\) in a canonical way. From the 2-functoriality of the simplicial cotensor in its exponent variable, \(f^l / \Delta = \Delta f\) and \(\epsilon^l / \Delta = \Delta \epsilon\). Hence, the pasting diagram displayed above-left equals the one displayed above-center, which equals the diagram above-right by naturality of whiskering.\(^{12}\) This latter diagram is a pasted composite of two absolute right lifting diagrams, and is then an absolute right lifting diagram in its own right by Lemma 2.4.1; this universal property says that any cone over \(d\) whose summit factors through \(f\) factors uniquely through the limit cone \((\text{lim}, \rho)\) through a map that then transposes along the adjunction \(f \dashv u\). Hence the diagram on the right-hand side of (2.4.3) is an absolute right lifting diagram as claimed. \(\square\)

By combining Theorem 2.4.2 with Proposition 2.1.12, we have immediately that:

2.4.4. COROLLARY. Equivalences preserve limits and colimits. \(\square\)

We can also prove a more refined result:

2.4.5. PROPOSITION. If \(A \simeq B\), then any family of diagrams in \(A\) admitting a limit or colimit in \(B\) also admits a limit or colimit in \(A\) that is preserved by the equivalence.

PROOF. By Proposition 2.1.12 the equivalence \(B \Rightarrow A\) is both left and right adjoint to its equivalence inverse, preserving both limits and colimits of the composite family of diagrams \(D \to A^l \Rightarrow B^l\). Via the invertible 2-cells of the equivalence \(A^l \simeq B^l\) constructed by applying \((-)^l : b\mathcal{K} \to b\mathcal{K}\) to the equivalence \(A \simeq B\), the preserved diagram \(D \to A^l \Rightarrow B^l \Rightarrow A^l\) is isomorphic to the original family of diagrams \(D \to A^l\). Thus, we conclude from Exercise 2.3.vi that a family of diagrams in \(A\) has a limit

\(^{12}\)By naturality of whiskering, \(e^l \cdot f / u / \rho = \rho \cdot e^l / \Delta\lim\), and since \(e^l / \Delta = \Delta \epsilon\), this composite equals \(\rho \cdot \Delta \epsilon\lim\).
or colimit if and only if its image in an equivalent \( \infty \)-category \( B \) does, and such limits and colimits are preserved by the functors of the equivalence.

We turn now to a limit-preservation result of another sort, which can be used to simplify the calculation of limits or colimits of diagrams with particular shapes. This simplification comes about by reindexing the diagrams, by restricting along a functor \( k: I \to J \). For a certain class of functors, called “initial” or “final,” this reindexing preserves and reflects limits or colimits, respectively.

At present, we give a teleological, rather than an intrinsic, description of these functors. The following definition makes sense for an arbitrary functor in a cartesian closed \( \infty \)-cosmos or for a map between simplicial sets serving as indexing shapes in an arbitrary \( \infty \)-cosmos. In Definition 9.5.5 we extend the adjectives “initial” and “final” to functors between \( \infty \)-categories in an arbitrary \( \infty \)-cosmos and prove that the classes of functors characterized there satisfy the property described here.

**2.4.6. Definition (initial and final functor).** A functor \( k: I \to J \) is **final** if \( J \)-indexed colimits exist if and only if, and in such cases coincide with, the restricted \( I \)-indexed colimits. That is, \( k: I \to J \) is final if and only if for any \( \infty \)-category \( A \), the square

\[
\begin{array}{ccc}
A & \longrightarrow & A \\
\Delta \downarrow & & \downarrow \Delta \\
A' & \longrightarrow & \Delta \\
\end{array}
\]

preserves and reflects all absolute left lifting diagrams.

Dually a functor \( k: I \to J \) is **initial** if this square preserves and reflects all absolute right lifting diagrams: or informally, if a generalized element defines a limit of a \( J \)-indexed diagram if and only if it defines a limit of the restricted \( I \)-indexed diagrams.

Historically, final functors were called “cofinal” with no obvious name for the dual notion. Our preferred terminology hinges on the following mnemonic: the inclusion of an initial element defines an initial functor, while the inclusion of a terminal (aka final) element defines a final functor. These facts are special cases of a more general result we now establish, using exactly the same tactics as deployed to prove Theorem 2.4.2.

**2.4.7. Proposition.** Left adjoints define initial functors and right adjoints define final functors.

**Proof.** If \( k \dashv r \) with unit \( \eta: \text{id}_I \Rightarrow rk \) and counit \( \epsilon: kr \Rightarrow \text{id}_J \), then cotensoring into \( A \) yields an adjunction

\[
\begin{array}{ccc}
A' & \leftrightarrow & A' \\
\downarrow \epsilon & & \downarrow \epsilon \\
Ak & \longrightarrow & \text{id}_{A'} \\
\end{array}
\]

with unit \( A^\eta: \text{id}_{A'} \Rightarrow AkA' \) and counit \( A^\epsilon: A' Ak \Rightarrow \text{id}_{A'} \).

To prove that \( k \) is initial we must show that for any \( \rho: \Delta \lim \to d \) as displayed below-left,
the left-hand diagram is an absolute right lifting diagram if and only if the right-hand diagram is an absolute right lifting diagram.

By Lemmas 2.3.6 and 2.4.1, the right-hand diagram is an absolute right lifting diagram if and only if the pasted composite displayed below-left

\[
\begin{array}{ccc}
D & \xrightarrow{d} & A^l \\
\downarrow & & \downarrow \rho \\
A & \xrightarrow{\Delta} & A
\end{array}
\quad =
\begin{array}{ccc}
D & \xrightarrow{d} & A^l \\
\downarrow & & \downarrow \rho \\
A & \xrightarrow{\Delta} & A
\end{array}
\]

is also an absolute right lifting diagram. On noting that \( A^v \Delta = \Delta \) and \( A^e \Delta = \text{id}_A \), the left-hand side reduces to the right-hand side, which proves the claim. \( \square \)

Exercise 2.3.v defines a functor \( f : A \to B \) between \( \infty \)-categories to be fully faithful just when

\[
\begin{array}{ccc}
A & \xrightarrow{\Delta} & A \\
\downarrow & & \downarrow \rho \\
A & \xrightarrow{\Delta} & A
\end{array}
\]

defines absolute right lifting diagram or equivalently an absolute left lifting diagram.

2.4.8. PROPOSITION. A fully faithful functor \( f : A \to B \) reflects any limits or colimits that exist in \( B \).

An alternate approach to proving this result, due to Sulyma [120, 3.7], is suggested as Exercise 3.5.iii.

PROOF. The statement for limits asserts that given any family of diagrams \( d : D \to A^I \) of shape \( I \) in \( A \), any functor \( \ell : D \to A \) and cone \( \rho : \Delta \ell \Rightarrow d \) as below-left so that the whiskered composite with \( f^I : A^I \to B^I \) displayed below is an absolute right lifting diagram

\[
\begin{array}{ccc}
D & \xrightarrow{d} & A^l \\
\downarrow & & \downarrow \rho \\
A & \xrightarrow{\Delta} & A
\end{array}
\]

then \( (\ell, \rho) \) defines an absolute right lifting of \( d : D \to A^I \) through \( \Delta : A \to A^I \). By Exercise 2.3.v, to say that \( f \) is fully faithful is to say that \( \text{id}_A : A \to A \) defines an absolute right lifting of \( f \) through itself. So by Lemma 2.4.1 and the hypothesis just stated, the composite diagram below-left is an absolute right lifting diagram, and by 2-functoriality of the simplicial cotensor with \( I \), the diagram below-left
Now if we knew that whenever $f : A \to B$ is a fully faithful functor that $f^l : A^l \to B^l$ is as well, then $id_{A^l} : A^l \to A^l$ defines an absolute right lifting of $f^l$ through itself. And indeed this is a case as a consequence of a more general result proven as Corollary 3.5.7: any cosmological functor, such as the functors $(-)^l : \mathcal{K} \to \mathcal{K}$ of Proposition 1.3.3(iii),(iv), preserves absolute lifting diagrams. Applying Lemma 2.4.1 again, we conclude that $(\ell, \rho)$ is an absolute right lifting of $d$ through $\Delta$ as required. □

It is worth asking why we haven’t already proven that cosmological functors preserve absolute lifting diagrams. For instance, we know from Lemma 1.4.4 that cosmological functors induce 2-functors between homotopy 2-categories, which is where absolute lifting diagrams are defined. The difference between the notion of absolute lifting diagram and, say, the case of adjunctions considered in Lemma 2.1.3, is that adjunctions are equationally defined, while the definition of an absolute lifting diagram employs several universal quantifiers.

This might lead one to suspect that in fact it’s not necessarily the case that every cosmological functor preserves absolute lifting diagrams. After all, cosmological functors can be “forgetful” or fail to be even essentially surjective. However, as we shall discover in Theorem 3.5.3, the universal property of absolute lifting diagrams can be re-expressed internally to the ambient $\infty$-cosmos by deploying the axiomatized limits of 1.2.1(i). Their preservation by cosmological functors is then a direct corollary.

Our final result requires the following representable characterization of absolute lifting diagrams whose proof again makes use of the fact that they are preserved by cosmological functors.

2.4.9. PROPOSITION. A natural transformation defined in an $\infty$-cosmos $\mathcal{K}$ as below-left is an absolute right lifting diagram if and only if its “externalization” displayed below-right defines a right lifting diagram in $\mathcal{QC}\text{at}$

\[
\begin{align*}
C &\xrightarrow{g} A \\
\downarrow^g & \quad \downarrow^f \\
\downarrow^s & \quad \downarrow^s \\
\downarrow^r & \quad \downarrow^r
\end{align*}
\]

that is preserved by precomposition with any functor $c : X \to C$ in $\mathcal{K}$ in the sense that the diagram below is also right lifting:

\[
\begin{align*}
\text{Fun}(C, B) &\xrightarrow{c^*} \text{Fun}(X, B) \\
\downarrow^{f_*} & \quad \downarrow^{f_*} \\
\text{Fun}(C, A) &\xrightarrow{c^*} \text{Fun}(X, A) \\
\downarrow^{g_*} & \quad \downarrow^{g_*}
\end{align*}
\]

Moreover the externalized right lifting diagrams in $\mathcal{QC}\text{at}$ are in fact absolute.
Since \( \text{Fun}(1, -) : \text{QCat} \to \text{QCat} \) is naturally isomorphic to the identity functor, for any \( \infty \)-categories \( C, A \in \mathcal{K} \) we have \( \text{Fun}(C, A) \cong \text{Fun}(1, \text{Fun}(C, A)) \) and hence

\[
\text{hFun}(X, A) \cong \text{hFun}(1, \text{Fun}(X, A)). \tag{2.4.10}
\]

This justifies our use of the same name \( \rho \) for the 2-cell in \( \mathcal{K} \) and the 2-cell in \( \text{hQCat} \) in the statement.

To say that \( (r, \rho) \) defines a right lifting of \( g \) through \( f \) in \( \mathcal{K} \) asserts a bijection, implemented by pasting with \( \rho \), between 2-cells in \( \text{hFun}(C, B) \) with codomain \( r \) and 2-cells in \( \text{hFun}(C, A) \) with codomain \( g \) and domain factoring through \( f \). Under the correspondence of (2.4.10), this asserts equally that \( r \) defines a right lifting of \( g \) through \( f^* \) in \( \text{hQCat} \). To say that \( (r, \rho) \) defines an absolute right lifting of \( g \) through \( f \) is to assert the analogous right lifting property for the pair \( (rc, \rho c) \) defined by restricting along any \( c : X \to C \). This is exactly the first claim of the statement.

It remains only to argue that if \( (r, \rho) \) is an absolute right lifting diagram in \( \mathcal{K} \), then its externalized right lifting diagram of quasi-categories is also absolute. To see this, first use Corollary 3.5.7 to note that the cosmological functor \( \text{Fun}(C, -) : \mathcal{K} \to \text{QCat} \) preserves this absolute right lifting diagram, yielding an absolute right lifting diagram of quasi-categories as below left:

\[
\begin{array}{ccc}
\text{Fun}(C, B) & \xrightarrow{\text{id}_C} & \text{Fun}(C, C) \\
\downarrow \text{Fun}(C, \rho) & & \downarrow \text{Fun}(C, \rho) \\
\text{Fun}(C, C) & \rightarrow & \text{Fun}(C, A)
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}(C, B) & \xrightarrow{\text{id}_C} & \text{Fun}(C, C) \\
\downarrow \text{Fun}(C, \rho) & & \downarrow \text{Fun}(C, \rho) \\
1 & \rightarrow & \text{Fun}(C, A)
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}(C, B) & \xrightarrow{\text{id}_C} & \text{Fun}(C, C) \\
\downarrow \text{Fun}(C, \rho) & & \downarrow \text{Fun}(C, \rho) \\
\text{Fun}(C, C) & \rightarrow & \text{Fun}(C, A)
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}(C, B) & \xrightarrow{\text{id}_C} & \text{Fun}(C, C) \\
\downarrow \text{Fun}(C, \rho) & & \downarrow \text{Fun}(C, \rho) \\
\text{Fun}(C, C) & \rightarrow & \text{Fun}(C, A)
\end{array}
\]

We obtain the desired absolute right lifting diagram by evaluating at the identity. \( \square \)

We now show, for \( I \) and \( J \) simplicial sets, that whenever we are given a \( J \)-indexed diagram valued in the \( \infty \)-category \( A^I \) of \( I \)-indexed diagrams in \( A \), its limit may be computed pointwise in the vertices of \( I \) as the limit of the corresponding \( J \)-indexed diagram in \( A \). Note this statement is not a biconditional. Even in the case of strict 1-categories, there may exist coincidental limits of diagram valued in functor categories that are not defined pointwise \([21, 2.17.10]\).

2.4.11. **Proposition.** Let \( I \) and \( J \) be simplicial sets and let \( A \) be an \( \infty \)-category. Then a diagram as below-left is an absolute right lifting diagram

\[
\begin{array}{ccc}
\lim_d & \rightarrow & A^I \\
\downarrow \text{id}_C & & \downarrow \Delta \\
D & \rightarrow & A^I \times J
\end{array}
\]

\[
\begin{array}{ccc}
\lim_d & \rightarrow & A^I \\
\downarrow \text{id}_C & & \downarrow \Delta \\
D & \rightarrow & A^I \times J
\end{array}
\]

if for each vertex \( i \in I \), the diagram above right is an absolute right lifting diagram.

**Proof.** By Proposition 2.4.9, we may externalize and instead show that the diagram of quasi-categories displayed below left

\[
\begin{array}{ccc}
\text{Fun}(D, A)^I & \xrightarrow{\text{id}_C} & \text{Fun}(D, A) \\
\downarrow \text{id}_C & & \downarrow \Delta \\
1 & \rightarrow & \text{Fun}(D, A)^I \times J
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}(D, A)^I & \xrightarrow{\text{id}_C} & \text{Fun}(D, A) \\
\downarrow \text{id}_C & & \downarrow \Delta \\
1 & \rightarrow & \text{Fun}(D, A)^I \times J
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}(D, A)^I & \xrightarrow{\text{id}_C} & \text{Fun}(D, A) \\
\downarrow \text{id}_C & & \downarrow \Delta \\
1 & \rightarrow & \text{Fun}(D, A)^I \times J
\end{array}
\]
is absolute right lifting lifting if the diagrams above-right are for each vertex \( i \in I \). By naturality of our methods, our proof will show that the absolute right lifting diagrams on the left are preserved by postcomposition with the restriction functors induced by \( d : X \to D \) if the same is true on the right.

We simplify our notation and write \( Q \) for the quasi-category \( \text{Fun}(D,A) \) and assume that for each \( i \in I \) the diagram

\[
\begin{array}{ccc}
1 & \xrightarrow{d} & Q^I \\
\downarrow \varrho & & \downarrow \Delta \\
\lim & \xrightarrow{\rho} & Q^{I \times I} \\
\end{array}
\]

is absolute right lifting. By 2-adjunction \((- \times I) \dashv (-)^I\), a diagram as below-left is absolute right lifting if and only if the transposed diagram below-right is a right lifting diagram and this remains the case upon restricting along functors of the form \( \pi : X \times I \to I \).

We'll argue that this right-hand diagram is in fact absolute right lifting, which implies that the left-hand diagram is absolute right lifting as well, as desired.

To see this we appeal to Proposition 12.2.9, which tells us that universal properties in \( \mathbf{QCat} \) are detected pointwise. Specifically, this tells us that the triangle above right is an absolute right lifting diagram if and only if the restricted diagram is absolute right lifting for each vertex \( i \in I \)

\[
\begin{array}{ccc}
1 & \xrightarrow{i} & I \\
\downarrow \varrho & & \downarrow \Delta \\
\lim & \xrightarrow{\rho} & Q^I \\
\end{array}
\]

and this is exactly what we have assumed in (2.4.12).

\[\square\]

**Exercises.**

2.4.i. **Exercise.** Show that any left adjoint \( f : B \to A \) between \( \infty \)-categories admitting all \( J \)-shaped colimits preserves them in the sense that the square of functors

\[
\begin{array}{ccc}
B^I & \xrightarrow{f^I} & A^I \\
\colim & \cong & \colim \\
B & \xrightarrow{f} & A \\
\end{array}
\]

commutes up to isomorphism.

\[\text{If the reader is concerned that } I \text{ is not a quasi-category, there are two ways to proceed. One is to replace } I \text{ by a quasi-category } I' \text{ by inductively attaching fillers for inner horns; note that } I \text{ and } I' \text{ will have the same sets of vertices. By Proposition 1.1.28, the diagram quasi-categories } Q^I' \text{ and } Q^I \text{ are equivalent. The other option is to observe that it doesn't matter if } I \text{ is a quasi-category or not, because we may define } h\text{Fun}(I, Q) := h(Q^I) \text{ and by Corollary 1.1.21 } Q^I \text{ is a quasi-category regardless of whether } I \text{ is.}\]

67
2.4.ii. EXERCISE. Prove Lemma 2.4.1.

2.4.iii. EXERCISE. Give a proof of Theorem 2.4.2 that does not appeal to Lemma 2.4.1 by directly verifying that the diagram on the right of (2.4.3) is an absolute right lifting diagram.

2.4.iv. EXERCISE (composite adjunctions, revisited). Use Lemma 2.4.1 to give a new proof of Proposition 2.1.9.

2.4.v. EXERCISE. For any composable pair of maps \( k: I \to J \) and \( \ell: J \to K \), show that if \( k \) and \( \ell k \) are final, then so is \( \ell \).
Comma $\infty$-Categories

In Chapter 2, we introduce adjunctions between $\infty$-categories and limits and colimits of diagrams valued within an $\infty$-category through definitions that are particularly expedient for establishing the expected interrelationships, as illustrated by the proof that right adjoint preserve limits. These definitions are 2-categorical in nature—stated in reference to the $\infty$-categories, $\infty$-functors, and $\infty$-natural transformations of the homotopy 2-category—but neither clearly articulates the universal properties of these notions. Definition 2.3.7 does not obviously express the expected universal property of the limit cone: namely, that a limit cone over a diagram $d$ defines a terminal element in the yet-to-be-defined $\infty$-category of cones over $d$. Nor does Definition 2.1.1 explain how an adjunction $f \dashv u$ induces an equivalence on the yet-to-be-defined hom-spaces $\text{Hom}_A(fb,a) \approx \text{Hom}_B(b,ua)$ for a pair of generalized elements. In this section, we make use of the axiomatized limits in an $\infty$-cosmos to exhibit a general construction that will specialize to define both this $\infty$-category of cones and also these hom-spaces. This construction also permits us to represent a functor between $\infty$-categories as an $\infty$-category, in dual “left” or “right” fashions, via which we can redefine an adjunction to consist of a pair of functors $f : B \to A$ and $u : A \to B$ so that the left representation of $f$ is equivalent to the right representation of $u$ over $A \times B$.

Our vehicle for all of these new definitions is the comma $\infty$-category associated to a cospan:

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A & \leftarrow B \\
\downarrow & & \downarrow \phi & & \downarrow \\
A & \rightarrow & B
\end{array}
\]

Our aim in this chapter is to develop the general theory of comma constructions from the point of view of the homotopy 2-category of an $\infty$-cosmos. Our first payoff for this work will occur in Chapter 4 where we study the universal properties of adjunctions, limits, and colimits in the sense of the ideas just outlined. The comma construction will also provide the essential vehicle in Part III for establishing the model-independence of the categorical notions we will introduce throughout this text.

There is a standard definition of a “comma object” that can be stated in any strict 2-category, defined as a particular weighted limit (see Example A.6.14). Comma $\infty$-categories do not satisfy this universal property in the homotopy 2-category, however. Instead, they satisfy a somewhat peculiar “weak” variant of the usual 2-categorical universal property that to our knowledge has not been discovered elsewhere in the categorical or homotopical literature, expressed in terms of something we call a smothering functor, which relates homotopy coherent and homotopy commutative diagrams of suitable shapes. To

\[A \text{ a 2-categorical version of this result — exhibiting a bijection between sets of 2-cells — appears as Lemma 2.3.6, but in an } \infty\text{-category we'd hope for a similar equivalence of hom-spaces.}\]
introduce these universal properties in a concrete rather than abstract framework, we start in §3.1 by considering smothering functors involving homotopy categories of quasi-categories. The intrepid and impatient reader may skip the entirety of §3.1 if they wish to instead first encounter these notions in their full generality.

In §3.2, we use a smothering functor to encode the weak universal property of the $\infty$-category of arrows $A^2$ associated to an $\infty$-category $A$, considered as an object in the homotopy 2-category. In §3.3, we briefly study the analogous weak universal properties associated to the pullback of an isofibration, which we exploit to prove that the pullback of an equivalence along an isofibration is an equivalence.

Comma $\infty$-categories are introduced in §3.4 where we describe their strict universal property as simplicially enriched limits as well as their weak universal property in the homotopy 2-category. Each of these has their uses, for instance in describing the induced actions on comma $\infty$-categories of various types of morphisms between their generating cospans. The weak 2-categorical universal property is put to use in §3.5 where we prove a general representability theorem that characterizes those comma $\infty$-categories that are right or left represented by a functor of $\infty$-categories, in the sense alluded to above. In Chapter 4, we reap the payoff for this work, achieving the desired representable characterizations of adjunctions, limits, and colimits as special cases of these general results.

In §3.6 we tighten the main theorem of §3.5 to say that a comma $\infty$-category $\text{Hom}_A(f, g)$ is right-represented by a functor if and only if the codomain-projection functor $p_1: \text{Hom}_A(f, g) \to C$ admits a terminal element, when considered as an object in the sliced $\infty$-cosmos $\mathcal{K}_C$ and left-represented if and only if the domain-projection functor $p_0: \text{Hom}_A(f, g) \to B$ admits an initial element as an object in $\mathcal{K}_B$. These results require a careful analysis of the subtle difference between the homotopy 2-category of a sliced $\infty$-cosmos and the sliced 2-category of the homotopy 2-category of an $\infty$-cosmos. The results appearing here could have been proven earlier, and indeed the reader was invited to compare these 2-categories in Exercise 1.4.viii, but we defer them until there is sufficient motivation to explore this technicality. Those readers who would prefer to stay out of the weeds are invited to skip this section in its entirety.

In an $\infty$-cosmos of $(\infty,1)$-categories, the representability theorem can be improved still further to say that $\text{Hom}_A(f, g)$ is right- or left-represented by a functor if and only if for all elements $c: 1 \to C$ or $b: 1 \to B$, respectively, the $\infty$-category $\text{Hom}_A(fc, g)$ has a terminal element or the $\infty$-category $\text{Hom}_A(fb, g)$ has an initial element. The proof, appearing in §12.2, requires “analytic” techniques, in contrast with the purely synthetic reasoning in this chapter.

### 3.1. Smothering Functors

Let $Q$ be a quasi-category. Recall from Lemma 1.1.12 that its homotopy category $\text{h}Q$ has

- the elements $1 \to Q$ of $Q$ as its objects;
- the set of homotopy classes of 1-simplices of $Q$ as its arrows, where parallel 1-simplices are homotopic just when they bound a 2-simplex whose remaining outer edge is degenerate; and
- a composition relation if and only if any chosen 1-simplices representing the three arrows bound a 2-simplex.

For a 1-category $J$, it is well-known in classical homotopy theory that the homotopy category of diagrams $\text{h}(Q^J)$ is not equivalent to the category $(\text{h}Q)^J$ of diagrams in the homotopy category — except in very special cases, such as when $J$ is a set; see Warning 2.3.3. The objects of $\text{h}(Q^J)$ are homotopy coherent diagrams of shape $J$ in $Q$, while the objects of $(\text{h}Q)^J$ are mere homotopy commutative diagrams. There is,
however, a canonical comparison functor

\[ h(Q^!) \to (hQ)^! \]

defined by applying \( h : QC\text{at} \to Cat \) to the evaluation functor \( Q^! \times J \to Q \) and then transposing; a homotopy coherent diagram is in particular homotopy commutative.

Our first aim in this section is to better understand the relationship between the arrows in the homotopy category \( hQ \) and what we'll refer to as the arrows of \( Q \), namely, the 1-simplices in the quasi-category. To study this we'll be interested in the quasi-category in which the arrows of \( Q \) live as elements, namely \( Q^2 \), where \( 2 = \Delta[1] \) is the nerve of the “walking” arrow. Our notation deliberately imitates the notation commonly used for the category of arrows: if \( C \) is a 1-category, then \( C^2 \) is the category whose objects are arrows in \( C \) and whose morphisms are commutative squares, regarded as a morphism from the arrow displayed vertically on the left-hand side to the arrow displayed vertically on the right-hand side. This notational conflation suggests our first motivating question: how does the homotopy category of \( Q^2 \) relate to the category of arrows in the homotopy category \( hQ \)?

3.1.1. Lemma. The canonical functor \( h(Q^2) \to (hQ)^2 \) is

(i) surjective on objects,

(ii) full, and

(iii) conservative, i.e., reflects invertibility of morphisms,

but not necessarily injective on objects nor faithful.

Proof. Surjectivity on objects asserts that every arrow in the homotopy category \( hQ \) is represented by a 1-simplex in \( Q \). This is the conclusion of Exercise 1.1.iii(iii) which outlines the proof of Lemma 1.1.12.

To prove fullness, consider a pair of arrows \( f \) and \( g \) in \( Q \) that form the source and target of a commutative square in \( hQ \). By (i), we may choose arbitrary 1-simplices representing each morphism and their common composite:

\[
\begin{array}{ccc}
\bullet & \xrightarrow{h} & \bullet \\
\downarrow f & & \downarrow g \\
\bullet & \xleftarrow{k} & \bullet
\end{array}
\]

By Lemma 1.1.12, every composition relation in \( hQ \) is witnessed by a 2-simplex in \( Q \); choosing a pair of such 2-simplices defines a diagram \( 2 \to Q^2 \), which represents a morphism from \( f \) to \( g \) in \( h(Q^2) \), proving fullness.

Surjectivity on objects and fullness of the functor \( h(Q^2) \to (hQ)^2 \) are special properties having to do with the diagram shape \( 2 \). Conservativity holds for generic diagram shapes by the second statement of Corollary 1.1.21.

We leave the construction of counterexamples illustrating the general failure of injectivity on objects and faithfulness to Exercise 3.1.i, with a hint.

The properties of the canonical functor \( h(Q^2) \to (hQ)^2 \) will reappear frequently, so we bestow them with a suggestive name:

3.1.2. Definition (smothering functor). A functor \( f : A \to B \) between 1-categories is **smothering** if it is surjective on objects, full, and conservative. That is, a functor is smothering if and only if it has the
right lifting property with respect to the set of functors:

\[
\begin{aligned}
&\emptyset & 1+1 & 2 \\
\downarrow & \quad & \downarrow & \downarrow \\
1 & 2 & 1
\end{aligned}
\]

Some elementary properties of smothering functors are established in Exercise 3.1.ii. The most important of these is:

3.1.3. Lemma (smothering fibers). Each fibre of a smothering functor is a non-empty connected groupoid.

Proof. Suppose \( f: A \to B \) is smothering and consider the fiber

\[
\begin{array}{ccc}
A_b & \longrightarrow & A \\
\downarrow & \quad & \downarrow f \\
1 & \longrightarrow & B
\end{array}
\]

cover an object \( b \) of \( B \). By surjectivity on objects, the fiber is non-empty. Its morphisms are defined to be arrows between objects in the fiber of \( b \) that map to the identity on \( b \). By fullness, any two objects in the fiber are connected by a morphism, indeed, by morphisms pointing in both directions. By conservativity, all the morphisms in the fiber are necessarily invertible. \( \square \)

The argument used to prove Lemma 3.1.1 generalizes to:

3.1.4. Lemma. If \( J \) is a 1-category that is free on a reflexive directed graph and \( Q \) is a quasi-category, then the canonical functor \( h(Q^J) \to (hQ)^J \) is smothering.

Proof. Exercise 3.1.iii. \( \square \)

Cotensors are one of the simplicial limit constructions enumerated in axiom 1.2.1(i). Other limit constructions listed there also give rise to smothering functors.

3.1.5. Lemma. For any pullback diagram of quasi-categories in which \( p \) is an isofibration

\[
\begin{array}{ccc}
A \times_E E & \longrightarrow & E \\
\downarrow & \quad & \downarrow p \\
A & \longrightarrow & B \\
\end{array}
\]

the canonical functor \( h(A \times_E E) \to hA \times hE \) is smothering.

Proof. As \( h: QCat \to Cat \) does not preserve pullbacks, the canonical comparison functor of the statement is not an isomorphism. It is however bijective on objects since the composite functor

\[
QCat \xrightarrow{h} Cat \xrightarrow{\text{obj}} Set
\]
passes to the underlying set of vertices of each quasi-category, and this functor does preserve pullbacks. For fullness, note that a morphism in \( hA \times hE \) is represented by a pair of 1-simplices \( \alpha: a \to a' \) and \( \epsilon: e \to e' \) in \( A \) and \( E \) whose images in \( B \) are homotopic, a condition that implies in particular
that \( f(a) = p(e) \) and \( f(a') = p(e') \). By Lemma 1.1.9, we can configure this homotopy however we like, and thus we choose a 2-simplex witness \( \beta \) so as to define a lifting problem

\[
\begin{array}{c}
\Lambda^1[2] \
\downarrow \\
\Lambda[2] \\
B
\end{array}
\quad \begin{array}{c}
\overset{\beta}{\Rightarrow} \\
p \\
\end{array}
\quad \begin{array}{c}
E \\
\end{array}
\quad \begin{array}{c}
\overset{\epsilon, \epsilon'}{\Rightarrow} \\
p \\
\end{array}
\quad \begin{array}{c}
E
\end{array}
\]

Since \( p \) is an isofibration, a solution exists, defining an arrow \( \tilde{\epsilon} : e \to e' \) in \( E \) in the same homotopy class as \( \epsilon \) so that \( p(\tilde{\epsilon}) = f(\alpha) \). The pair \( (\alpha, \tilde{\epsilon}) \) now defines the lifted arrow in \( h(E \times_B A) \).

Finally, consider an arrow \( 2 \to A \times E \) whose image in \( hA \times hE \) is an isomorphism, which is the case just when the projections to \( E \) and \( A \) define isomorphisms. By Corollary 1.1.16, we may choose a homotopy coherent isomorphism \( 1 \to A \) extending the given isomorphism \( 2 \to A \). This data presents us with a lifting problem

\[
\begin{array}{c}
2 \\
\downarrow \\
\downarrow \\
1
\end{array}
\quad \begin{array}{c}
\overset{\alpha}{\Rightarrow} \\
p \\
\end{array}
\quad \begin{array}{c}
A \times E \\
\downarrow \\
A
\end{array}
\quad \begin{array}{c}
E \\
\downarrow \\
B
\end{array}
\]

which Exercise 1.1.vi tells us we can solve. This proves that \( h(A \times E) \to hA \times hE \) is conservative and hence also smoothering.

A similar argument proves:

3.1.6. LEMMA. For any tower of isofibrations between quasi-categories

\[
\cdots \to E_n \to E_{n-1} \to \cdots \to E_2 \to E_1 \to E_0
\]

the canonical functor \( h(\lim_n E_n) \to \lim_n hE_n \) is smoothering.

PROOF. Exercise 3.1.iv.

3.1.7. LEMMA. For any cospan between quasi-categories \( C \xrightarrow{g} A \leftarrow f B \) consider the quasi-category defined by the pullback

\[
\begin{array}{c}
\text{Hom}_A(f, g) \\
\downarrow a \\
C \times B \\
\downarrow \text{dom, cod} \\
A \times A
\end{array}
\]

The canonical functor \( h\text{Hom}_A(f, g) \to h\text{Hom}_{hA}(h_f, h_g) \) is smoothering.
PROOF. Here, the codomain is the category defined by an analogous pullback in $\mathcal{C}at$
\[
\begin{array}{ccc}
\text{Hom}_{hA}(hf, hg) & \longrightarrow & (hA)^2 \\
\downarrow & & \downarrow_{\text{(cod, dom)}} \\
hC \times hB & \xrightarrow{hg \times hf} & hA \times hA
\end{array}
\]
and the canonical functor factors as
\[
h\text{Hom}_A(f, g) \rightarrow h(A^2) \times_{hA \times hA} (hC \times hB) \rightarrow (hA)^2 \times_{hA \times hA} (hC \times hB)
\]
By Lemma 3.1.5 the first of these functors is smothering. By Lemma 3.1.1 the second is a pullback of a
smothering functor. By Exercise 3.1.ii(i) it follows that the composite functor is smothering. \qed

In the sections that follow, we will discover that the smothering functors just constructed express
particular “weak” universal properties of arrow, pullback, and comma constructions in the homotopy
2-category of any $\infty$-cosmos. It is to the first of these that we now turn.

Exercises.

3.1.i. Exercise. Find an explicit example of a quasi-category $Q$ for which the canonical smothering
functor $h(Q^2) \rightarrow (hQ)^2$ fails to be

(i) injective on objects and

(ii) faithful

for instance by defining $Q$ to be the total singular complex of a suitable topological space.

3.1.ii. Exercise. Prove that:

(i) The class of smothering functors is closed under composition, retract, product, and pullback.

(ii) The class of smothering functors contains all surjective equivalences of categories.

(iii) All smothering functors are isofibrations, that is, maps that have the right lifting property with
respect to $1 \hookrightarrow I$.

(iv) Prove that if $f$ and $gf$ are smothering functors, then $g$ is a smothering functor.$^2$

3.2. $\infty$-Categories of Arrows

In this section, we replicate the discussion from the start of the previous section using an arbitrary
$\infty$-category $A$ in place of the quasi-category $Q$. The analysis of the previous section could have been
developed natively in this general setting but at the cost of an extra layer of abstraction and more
confusing notation — with a functor space $\text{Fun}(X, A)$ replacing the quasi-category $Q$.

Recall an element of an $\infty$-category is defined to be a functor $1 \rightarrow A$. Tautologically, the elements
of $A$ are the vertices of the underlying quasi-category $\text{Fun}(I, A)$ of $A$. In this section, we will define
and study an $\infty$-category $A^2$ whose elements are the 1-simplices in the underlying quasi-category of $A$.
We refer to $A^2$ as the $\infty$-category of arrows in $A$ and call its elements simply arrows of $A$.

$^2$It suffices, in fact, to merely assume that $f$ is surjective on objects and arrows.
In fact, we’ve tacitly introduced this construction already. Recall 
2 is our preferred notation for the quasi-category Δ[1], as this coincides with the nerve of the 1-category 2 with a single non-identity morphism 0 → 1.

3.2.1. Definition (arrow ∞-category). Let A be an ∞-category. The ∞-category of arrows in A is the simplicial cotensor A^2 together with the canonical endpoint-evaluation isofibration

\[ A^2 := A^\Delta[1] \xrightarrow{(p_1,p_0)} A^{\partial \Delta[1]} \cong A \times A \]

induced by the inclusion \( \partial \Delta[1] \hookrightarrow \Delta[1] \). For conciseness, we write \( p_0 : A^2 \rightarrow A \) for the domain-evaluation induced by the inclusion \( 0 : \mathbb{1} \hookrightarrow 2 \) and write \( p_1 : A^2 \rightarrow A \) for the codomain-evaluation induced by \( 1 : \mathbb{1} \hookrightarrow 2 \).

As an object of the homotopy 2-category \( \mathcal{K} \), the ∞-category of arrows comes equipped with a canonical 2-cell that we now construct.

3.2.2. Lemma (generic arrow). For any ∞-category A, the ∞-category of arrows \( A^2 \) comes equipped with a canonical 2-cell

\[ A^2 \xrightarrow{\kappa} A \]

that we refer to as the generic arrow with codomain A.

Proof. The simplicial cotensor has a strict universal property described in Digression 1.2.6: namely \( A^2 \) is characterized by the natural isomorphism

\[ \text{Fun}(X, A^2) \cong \text{Fun}(X, A)^2. \]  

(3.2.4)

By the Yoneda lemma, the data of the natural isomorphism (3.2.4) is encoded by its “universal element”, which is defined to be the image of the identity at the representing object. Here the identity functor \( \text{id} : A^2 \rightarrow A^2 \) is mapped to an element of \( \text{Fun}(A^2, A)^2 \), a 1-simplex in \( \text{Fun}(A^2, A) \) which represents a 2-cell \( \kappa \) in the homotopy 2-category defining (3.2.3).

To see that the source and target of \( \kappa \) must be the domain-evaluation and codomain-evaluation functors, note that the action of the simplicial cotensor \( A^{(-)} \) on morphisms of simplicial sets is defined so that the isomorphism (3.2.4) is natural in the cotensor variable as well. Thus, by restricting along the endpoint inclusion \( \mathbb{1} + \mathbb{1} \hookrightarrow 2 \), we may regard the isomorphism (3.2.4) as lying over the natural isomorphism \( \text{Fun}(X, A \times A) \cong \text{Fun}(X, A) \times \text{Fun}(X, A) \).

\[ \begin{align*}
\text{Fun}(X, A^2) & \cong \text{Fun}(X, A)^2 \\
\downarrow (p_1,p_0) & \downarrow (\text{cod}, \text{dom}) \\
\text{Fun}(X, A \times A) & \cong \text{Fun}(X, A) \times \text{Fun}(X, A)
\end{align*} \]

The identity functor maps around the top-right composite to the pair of functors \( (\kappa, \text{dom} \kappa) \) and around the left-bottom composite to the pair \( (p_1, p_0) \).

There is a 2-categorical limit notion that is analogous to Definition 3.2.1, which constructs, for any object A, the universal 2-cell with codomain A: namely the (categorical) cotensor with the 1-category 2. Its universal property is analogous to (3.2.4) but with the hom-categories of the 2-category in place of the functor spaces; see §A.4. In \( \mathbf{Cat} \) this constructs the arrow category associated to a 1-category.
In the homotopy 2-category $\mathcal{K}$, by the Yoneda lemma again, the data (3.2.3) encodes a natural transformation

$$\text{hFun}(X, A^2) \to \text{hFun}(X, A)^2$$

of categories but this is not a natural isomorphism, nor even a natural equivalence of categories. However, it does furnish the $\infty$-category of arrows with a “weak” universal property of the following form:

3.2.5. PROPOSITION (the weak universal property of the arrow $\infty$-category). The generic arrow (3.2.3) with codomain $A$ has a weak universal property in the homotopy 2-category given by three operations:

(i) **1-cell induction**: Given a 2-cell over $A$ as below-left

$$\begin{array}{c}
X \\
\downarrow^a \\
A
\end{array}$$

there exists a 1-cell $\alpha^\tau: X \to A^2$ so that $s = p_0^\tau \alpha^\tau$, $t = p_1^\tau \alpha^\tau$, and $\alpha = \kappa^\tau \alpha^\tau$.

(ii) **2-cell induction**: Given a pair of functors $a, a': X \to A^2$ and a pair of 2-cells $\tau_0$ and $\tau_1$ so that

$$\begin{array}{ccc}
A^2 \\
\downarrow^p_1 & \Leftarrow & \kappa \equiv p_0 \\
A
\end{array}$$

there exists a 2-cell $\tau: a \Rightarrow a'$ so that

$$(\begin{array}{ccc}
A^2 \\
\downarrow^p_1 & \Leftarrow & \kappa \equiv p_0 \\
A
\end{array})$$

and

$$(\begin{array}{ccc}
A^2 \\
\downarrow^p_1 & \Leftarrow & \kappa \equiv p_0 \\
A
\end{array})$$

(iii) **2-cell conservativity**: For any 2-cell

$$\begin{array}{c}
X \\
\downarrow^a \\
A^2
\end{array}$$

if both $p_1 \tau$ and $p_0 \tau$ are isomorphisms then $\tau$ is an isomorphism.
Proof. Let $Q = \text{Fun}(X, A)$ and apply Lemma 3.1.1 to observe that the natural map of hom-categories

$$
\begin{align*}
\text{hFun}(X, A^2) &\xrightarrow{(\psi_1, \psi_0)} \text{hFun}(X, A) \times \text{hFun}(X, A) \\
\text{hFun}(X, A) \times \text{hFun}(X, A) &\xrightarrow{(\text{cod}, \text{dom})} \text{hFun}(X, A^2)
\end{align*}
$$

over $\text{hFun}(X, A \times A) \cong \text{hFun}(X, A) \times \text{hFun}(X, A)$ is a smothering functor. Surjectivity on objects is expressed by 1-cell induction, fullness by 2-cell induction, and conservativity by 2-cell conservativity. □

Note that the functors $\lceil \alpha \rceil : X \to A$ that represent a given 2-cell $\alpha$ with domain $X$ and codomain $A$ are not unique. However, they are unique up to “fibered” isomorphisms that whisker with $(p_1, p_0) : A \to A \times A$ to an identity 2-cell:

3.2.6. Proposition. Whiskering with (3.2.3) induces a bijection between 2-cells with domain $X$ and codomain $A$ as displayed below-left

$$
\begin{align*}
\left\{ \begin{array}{c} X \\ \frac{s}{\rho_\alpha} \\ \frac{t}{\iota} \end{array} \right\} &\leftrightarrow \left\{ \begin{array}{c} X \\ \frac{t}{\alpha^*} \\ \frac{s}{\iota} \end{array} \right\} \\
\end{align*}
$$

and fibered isomorphism classes of functors $X \to A^2$ as displayed above-right, where the fibered isomorphisms are given by invertible 2-cells

$$
\begin{align*}
\begin{array}{ccc}
X & & A \\
\downarrow{t} & \alpha^* & \downarrow{\iota} \\
A^2 & \equiv & A \\
\end{array}
\end{align*}
$$

so that $p_0 \gamma = \text{id}_s$ and $p_1 \gamma = \text{id}_t$.

Proof. Lemma 3.1.3 proves that the fibers of the smothering functor of Proposition 3.2.5 are connected groupoids. The objects of the fiber over $\alpha$ are functors $X \to A^2$ that whisker with the generic arrow $\kappa$ to $\alpha$, and the morphisms are invertible 2-cells that whisker with $(p_1, p_0) : A^2 \to A \times A$ to the identity 2-cell $(\text{id}_s, \text{id}_t)$. The action of the smothering functor defines a bijection between the objects of its codomain and their corresponding fibers. □

Our final task is to observe that the universal property of Proposition 3.2.5 is also enjoyed by any object $(e_1, e_0) : E \to A \times A$ that is equivalent to the $\infty$-category of arrows $(p_1, p_0) : A^2 \to A \times A$ in the slice $\infty$-cosmos $\mathcal{K}_{/A\times A}$. We have special terminology to allow us to concisely express the type of equivalence we have in mind.
3.2.7. **Definition** (fibered equivalence). A **fibered equivalence** over an ∞-category $B$ in an ∞-cosmos $\mathcal{K}$ is an equivalence

$$
\begin{array}{ccc}
E & \sim & F \\
\downarrow & & \downarrow \\
B & \sim & B
\end{array}
$$

(3.2.8)

in the sliced ∞-cosmos $\mathcal{K}_{/B}$. We write $E \cong_B F$ to indicate that the specified isofibrations with these domains are equivalent over $B$.

By Proposition 1.2.22(vii), a fibered equivalence is just a map between a pair of isofibrations over a common base that defines an equivalence in the underlying ∞-cosmos: the forgetful functor $\mathcal{K}_{/B} \to \mathcal{K}$ preserves and reflects equivalences. Note, however, that it does not create them: it is possible for two ∞-categories $E$ and $F$ to be equivalent without there existing any equivalence compatible with a pair of specified isofibrations $E \twoheadrightarrow B$ and $F \twoheadrightarrow B$.

3.2.9. **Warning.** At this point, there is some ambiguity about the 2-categorical data that presents a fibered equivalence related to the question posed in Exercise 1.4.viii. But since Proposition 1.2.22(vii) tells us that a mere equivalence in $\mathbf{hK}$ involving a functor of the form (3.2.8) is sufficient to guarantee that this as-yet-unspecified 2-categorical data exists, we defer a careful analysis of this issue to §3.6.

3.2.10. **Proposition** (uniqueness of arrow ∞-categories). For any isofibration $(e_1, e_0) : E \twoheadrightarrow A \times A$ that is fibered equivalent to $(p_1, p_0) : A \overset{\twoheadrightarrow}{\rightarrow} A \times A$ the 2-cell

$$
\begin{array}{ccc}
E & \cong & A \\
\downarrow & \cong & \downarrow \\
e_0 & \cong & e_1
\end{array}
$$

encoded by the equivalence $E \twoheadrightarrow A^2$ satisfies the weak universal property of Proposition 3.2.5. Conversely, if the isofibrations $(d_1, d_0) : D \twoheadrightarrow A \times A$ and $(e_1, e_0) : E \twoheadrightarrow A \times A$ are equipped with 2-cells

$$
\begin{array}{ccc}
D & \cong & A \\
\downarrow & \cong & \downarrow \\
d_0 & \cong & d_1
\end{array}
$$

and

$$
\begin{array}{ccc}
E & \cong & A \\
\downarrow & \cong & \downarrow \\
e_0 & \cong & e_1
\end{array}
$$

satisfying the weak universal property of Proposition 3.2.5, then $D \cong_{A \times A} E$.

**Proof.** We prove the first statement. By the defining equation of 1-cell induction $e = \kappa e$, where $\kappa$ is the canonical 2-cell of (3.2.3). Hence, the functor induced by pasting with $e$ factors as a composite

$$
\begin{array}{ccc}
h\text{Fun}(X, E) & \xrightarrow{e_*} & h\text{Fun}(X, A^2) & \xrightarrow{(p_1)_*(p_0)_*)} & h\text{Fun}(X, A)^2 \\
\downarrow & & \downarrow \cong & & \downarrow \cong \\
h\text{Fun}(X, A) \times h\text{Fun}(X, A) & \xrightarrow{(\text{cod}, \text{dom})} & h\text{Fun}(X, A) \times h\text{Fun}(X, A)
\end{array}
$$

and our task is to prove that this composite functor is smothering. We see that the first functor, defined by post-composing with the equivalence $e : E \rightarrow A^2$, is an equivalence of categories, and the second functor is smothering. Thus, the composite is clearly full and conservative. To see that it is also surjective on objects, note first that by 1-cell induction any 2-cell

$$
\begin{array}{ccc}
X & \cong & A \\
\downarrow & \cong & \downarrow \\
s & \cong & f
\end{array}
$$
is represented by a functor $\tilde{\alpha} : X \to A^2$ over $A \times A$. Composing with any fibered inverse equivalence $e'$ to $e$ yields a functor

$$
\begin{array}{ccc}
X & \xrightarrow{\alpha} & A^2 \\
(p_1 p_0) & & \downarrow \sim \downarrow \alpha'
\end{array}
$$

whose image after post-composing with $e$ is isomorphic to $\tilde{\alpha}$ over $A \times A$. Because this isomorphism is fibered in the sense of Proposition 3.2.6, the image of $e'\alpha'$ under the functor $h\text{Fun}(X, E) \to h\text{Fun}(X, A)^2$ returns the 2-cell $\alpha$. This proves that this mapping is surjective on objects and hence defines a smothering functor as claimed.

The converse is left to Exercise 3.2.ii and proven in a more general context in Proposition 3.4.11. □

3.2.11. CONVENTION. On account of Proposition 3.2.10, we extend the appellation "$\infty$-category of arrows" from the strict model constructed in Definition 3.2.1 to any $\infty$-category that is fibered equivalent to it.

Via Lemma 3.1.4, the discussion of this section extends to establish corresponding weak universal properties for the cotensors $A^I$ of an $\infty$-category $A$ with a free category $I$. We leave the exploration of this to the reader.

**Exercises.**

3.2.i. **Exercise.**

(i) Prove that a parallel pair of 1-simplices $f, g : x \to y$ in a quasi-category $Q$ are homotopic if and only if they are isomorphic as elements of $Q^2$ via an isomorphism that projects to an identity along $(p_1, p_0) : Q^2 \to Q \times Q$.

(ii) Conclude that a parallel pair of 1-arrows in the functor space $\text{Fun}(X, A)$ between two $\infty$-categories $X$ and $A$ in any $\infty$-cosmos represent the same natural transformation if and only if they are isomorphic as elements of $\text{Fun}(X, A)^2 \cong \text{Fun}(X, A^2)$ via an isomorphism whose domain and codomain components are an identity.

(iii) Conclude that a parallel pair of 1-arrows in the functor space $\text{Fun}(X, A)$, which may be encoded as functors $X \to A^2$, represent the same natural transformation if and only if they are connected by a fibered isomorphism:

$$
\begin{array}{ccc}
X & \xrightarrow{\alpha} & A^2 \\
(p_1 p_0) & & \downarrow
\end{array}
$$

3.2.ii. **Exercise.** Prove the converse implication of Proposition 3.2.10.

3.2.iii. **Exercise.** Extend the results of Propositions 3.2.5 and Proposition 3.2.6 to describe the weak universal property of the cotensor $A^I$ of an $\infty$-category $A$ by a category $I$ that is freely generated from some reflexive directed graph.
3.3. Pullbacks of Isofibrations and Right Properness

Pullback and limits of towers of isofibrations in an ∞-cosmos also have weak 2-dimensional universal properties in the homotopy 2-category. We make limited use of these, preferring to exploit the strict universal properties of the simplicially enriched limits instead. However, the weak 2-dimensional universal property of pullbacks can be used to prove that equivalences pull back along isofibrations to equivalences and prove the equivalence-invariance of pullbacks in an ∞-cosmos.

3.3.1. Proposition (the weak universal property of the pullback). The pullback of an isofibration along a functor in an ∞-cosmos

\[
\begin{array}{ccc}
A \times E & \xrightarrow{g} & E \\
\downarrow q & & \downarrow p \\
A & \xrightarrow{f} & B
\end{array}
\]

has a weak universal property in the homotopy 2-category given by three operations:

(i) 1-cell induction: Commutative squares \(pe = f \alpha\) over the cospan underlying a pullback diagram factor uniquely through the pullback square

(ii) 2-cell induction: Given a pair of functors \(x, x' : X \to A \times E\) and a pair of 2-cells \(\alpha : qx \Rightarrow qx'\) and \(\epsilon : gx \Rightarrow gx'\) as below-left so that \(pe = f \alpha\) there exists a 2-cell \(\tau : x \Rightarrow x'\) as below-right so that \(q\tau = \alpha\) and \(g\tau = \epsilon\).

(iii) 2-cell conservativity: For any 2-cell

\[
\begin{array}{ccc}
X & \xrightarrow{x} & A \times E \\
\tau \downarrow & & \downarrow \\
X & \xrightarrow{x'} & A \times E
\end{array}
\]

if both \(q\tau\) and \(g\tau\) are isomorphisms then \(\tau\) is an isomorphism.
**Proof.** Apply Lemma 3.1.5 to the pullback diagram of quasi-categories

\[
\begin{array}{ccc}
\text{Fun}(X, A \times E) & \xrightarrow{g_*} & \text{Fun}(X, E) \\
q_* & \downarrow & p_* \\
\text{Fun}(X, A) & \xrightarrow{f_*} & \text{Fun}(X, B)
\end{array}
\]

to observe that the natural map of hom-categories

\[
\text{hFun}(X, A \times E) \longrightarrow \text{hFun}(X, A) \times \text{hFun}(X, B) \times \text{hFun}(X, E)
\]

is a bijective-on-objects smothering functor. Bijectivity on objects is expressed by 1-cell induction, fullness by 2-cell induction, and conservativity by 2-cell conservativity.

Using the weak 2-categorical universal property of the pullback, we can show that \(\infty\)-cosmoi are **right proper**, meaning that the pullback of any equivalence along an isofibration defines an equivalence.

3.3.2. **Proposition.** In any \(\infty\)-cosmos, the pullback of an equivalence along an isofibration is an equivalence.

\[
\begin{array}{ccc}
F & \xrightarrow{g_*} & E \\
q & \downarrow & p \\
A & \xrightarrow{f} & B
\end{array}
\]

**Proof.** By Proposition 2.1.12, we may choose an adjoint equivalence inverse to \(f\) and pick invertible 2-cells \(\alpha: \text{id}_A \cong f^{-1}f\) and \(\beta: ff^{-1} \cong \text{id}_B\) satisfying the triangle equalities in the homotopy 2-category. It is for this reason that we work with the 2-categorical universal property of the pullback rather than the simplicially enriched universal property. Now since the map \(p\) is an isofibration, we may use Proposition 1.4.10 to lift the isomorphism \(\beta p: ff^{-1}p \cong p\) along \(p\) to define an isomorphism \(e: e \cong \text{id}_E\) with codomain \(\text{id}_E: E \to E\). By construction \(pe = ff^{-1}p\), so by 1-cell induction the pair \((f^{-1}p, e)\) induces a map \(g^{-1}: E \to F\) so that \(qg^{-1} = f^{-1}p\) and \(gg^{-1} = e\). In this way we obtain an isomorphism \(e: gg^{-1} \cong \text{id}_E\) with \(pe = \beta p\).

Now by 2-cell induction and conservativity of Proposition 3.3.1, to define an isomorphism \(\text{id}_E \cong g^{-1}g\), it suffices to exhibit a pair of isomorphisms

\[
\alpha q: q \cong f^{-1}f q = f^{-1}pq = qq^{-1}g \quad \text{and} \quad e^{-1}g: g \cong gg^{-1}g
\]

so that \(f\alpha q = pe^{-1}g\). This latter equation holds because \(pe^{-1}g = \beta^{-1}pq = \beta^{-1}fq = f\alpha q\) by the triangle equality \(\beta f \cdot f\alpha = \text{id}_F\) for the adjoint equivalence \(f \dashv f^{-1}\). Thus, we may lift the data of an inverse equivalence to \(f\) to define an inverse equivalence to its pullback \(g\).

As a consequence of right properness, we can show that pullback is an equivalence invariant construction in any \(\infty\)-cosmos.
3.3.3. **Proposition.** Given a diagram of isofibrations and equivalences in any $\infty$-cosmos

\[
\begin{array}{ccc}
    C & \overset{g}{\rightarrow} & A \\
    \downarrow{r} & \searrow{t} & \downarrow{p} \\
    \tilde{C} & \overset{\tilde{g}}{\rightarrow} & \tilde{A} & \leftarrow \tilde{B} \\
\end{array}
\]

the induced map $C \times_A B \rightarrow \tilde{C} \times_{\tilde{A}} \tilde{B}$ between the pullbacks of the horizontal rows is again an equivalence.

**Proof.** By factoring via Lemma 1.2.16, we can replace the map $\tilde{g}$ by an isofibration. By the 2-of-3 property and the right properness of Proposition 3.3.2, the pullback of this isofibration along the equivalence $p$ is equivalent to the map $g$:

\[
\begin{array}{ccc}
    C & \overset{g}{\rightarrow} & P \rightarrow A \\
    \downarrow{r} & \searrow{t} & \downarrow{p} \\
    \tilde{C} & \overset{\tilde{g}}{\rightarrow} & P \rightarrow \tilde{A} \\
\end{array}
\]

By right properness again, the pullback of $P \rightarrow A$ along $f$ is equivalent to the pullback of $C \rightarrow A$ along $f$ and similarly for the lower-horizontal maps. So without loss of generality, we may assume that the maps $g$ and $\tilde{g}$ of the statement are fibrations and the left-hand square is a pullback.

Under these new hypothesis, the top, bottom, and front faces of the cube are pullback squares:

\[
\begin{array}{ccc}
    C \times B & \overset{f}{\rightarrow} & B \\
    \downarrow{A} & \searrow{q} & \downarrow{B} \\
    C & \overset{g}{\rightarrow} & A \\
    \downarrow{r} & \searrow{i} & \downarrow{p} \\
    \tilde{C} \times \tilde{B} & \overset{\tilde{f}}{\rightarrow} & \tilde{B} \\
\end{array}
\]

so by pullback composition and cancelation, the back face is a pullback square as well. Now the induced map $C \times_A B \rightarrow \tilde{C} \times_{\tilde{A}} \tilde{B}$ is the pullback of the equivalence $q$ along an isofibration and hence is an equivalence by Proposition 3.3.2.

**Exercises.**

3.3.i. **Exercise.** State and prove an analogous result to Proposition 3.3.1 that describes the weak 2-categorical universal property of limits of towers of isofibrations.

3.3.ii. **Exercise.** Use the result of Exercise 3.3.i to prove that a natural equivalence between towers of isofibrations induces an equivalence between their limits by adapting the construction given in the proofs of Proposition 3.3.2 and 3.3.3.
3.4. The Comma Construction

The *comma* $\infty$-category is defined by restricting the domain and codomain of the $\infty$-category of arrows $A^2$ along a pair of specified functors with codomain $A$.

3.4.1. Definition (comma $\infty$-category). Let $C \xrightarrow{g} A \xleftarrow{f} B$ be a diagram of $\infty$-categories. The *comma $\infty$-category* is constructed as a pullback of the simplicial cotensor $A^2$ along $g \times f$

\[
\begin{array}{ccl}
\text{Hom}_A(f, g) & \xrightarrow{\phi} & A^2 \\
(p_1, p_0) \downarrow & & \downarrow (p_1, p_0) \\
C \times B & \xrightarrow{g \times f} & A \times A
\end{array}
\]

(3.4.2)

This construction equips the comma $\infty$-category with a specified isofibration $(p_1, p_0) : \text{Hom}_A(f, g) \rightarrow C \times B$ and a canonical 2-cell

\[
\begin{array}{c}
\text{Hom}_A(f, g) \\
\downarrow \phi \\
\downarrow \phi \\
C \xrightarrow{g} B \\
\downarrow \phi \\
A \xleftarrow{f}
\end{array}
\]

(3.4.3)

in the homotopy 2-category called the *comma cone*.

By the universal property (3.4.2), an element of $\text{Hom}_A(f, g)$ is a triple $(\alpha, b, c) : 1 \rightarrow \text{Hom}_A(f, g)$ where $b$ and $c$ are elements of $B$ and $C$, respectively, and $\alpha : fb \rightarrow gc$ is an arrow in $A$ with domain $fb$ and codomain $gc$.

3.4.4. Example (arrow $\infty$-categories as comma $\infty$-categories). The $\infty$-category of arrows arises as a special case of the comma construction applied to the identity span. This provides us with alternate notation for the generic arrow of (3.2.3), which may be regarded as a particular instance of a comma cone.

\[
\begin{array}{c}
\text{Hom}_A \\
\downarrow \phi \\
\downarrow \phi \\
A \xrightarrow{\phi} A
\end{array}
\]

The following proposition encodes the homotopical properties of the comma construction.

3.4.5. Proposition (maps between commas). A commutative diagram

\[
\begin{array}{c}
C \xrightarrow{\overline{g}} A \xleftarrow{\overline{f}} B \\
\downarrow p \downarrow q \\
\overline{C} \xrightarrow{\overline{f}} \overline{A} \xleftarrow{\overline{f}} B
\end{array}
\]

The following proposition encodes the homotopical properties of the comma construction.
induces a map between the comma $\infty$-categories

\[ \text{Hom}_A(f, g) \xrightarrow{\text{Hom}_p(q, r)} \text{Hom}_A(f', g') \]

Moreover, if $p$, $q$, and $r$ are all

(i) equivalences,
(ii) isofibrations, or
(iii) trivial fibrations

then the induced map is again an equivalence, isofibration, or trivial fibration, respectively.

**Proof.** The map of cospans gives rise to a commutative diagram

\[ C \times B \xrightarrow{g \times f} A \times A \xleftarrow{(p_1, p_0)} A^2 \]

\[ r \times q \]

\[ p \times p \]

\[ C \times B \xrightarrow{g \times f} A \times A \xleftarrow{(p_1, p_0)} A^2 \]

in which the dashed map is the Leibniz tensor of the monomorphism $\mathbb{1} + \mathbb{1} \hookrightarrow \mathbb{2}$ with $p$. If $p$, $q$, and $r$ are fibrations or trivial fibrations, then this map and the four other downwards pointing maps are all fibrations or trivial fibrations, respectively, by axiom 1.2.1(ii) and Lemma 1.2.14. Now Proposition C.1.12 applies to prove that the map $\text{Hom}_p(q, r)$ is again a fibration or trivial fibration; see Exercise 3.4.i. In the case where $p$, $q$, and $r$ are equivalences, Lemma 1.2.18 can be used to directly verify that the maps $r \times q$, $p \times p$, and $p^2$ are as well. Now Proposition 3.3.3 applies to prove the first statement. 

There is a 2-categorical limit notion that is analogous to Definition 3.4.1, which constructs the universal 2-cell inhabiting a square over a specified cospan. In $\text{Cat}$ the category so-constructed is referred to as a comma category, from whence we borrow the name. As with the case of $\infty$-categories of arrows, comma $\infty$-categories do not satisfy this 2-universal property strictly. Instead:

3.4.6. **Proposition** (the weak universal property of the comma $\infty$-category). The comma cone (3.4.3) has a weak universal property in the homotopy 2-category given by three operations:

(i) **1-cell induction:** Given a 2-cell over $\xymatrix{C \ar[r]^g & A \ar[l]_f \ar[d]^p \ar[r] & B}$ as below-left:

\[ \begin{array}{c}
\text{Hom}_A(f, g) \\
\text{Hom}_p(q, r)
\end{array} \]

\[ C \times B \xrightarrow{g \times f} A \times A \xleftarrow{(p_1, p_0)} A^2 \]

\[ r \times q \]

\[ p \times p \]
there exists a 1-cell \( \alpha: X \to \mathbf{Hom}_A(f, g) \) so that \( b = p_0 \alpha \), \( c = p_1 \alpha \), and \( \alpha = \phi \alpha \).

(ii) 2-cell induction: Given a pair of functors \( a, a': X \to \mathbf{Hom}_A(f, g) \) and a pair of 2-cells \( \tau_0 \) and \( \tau_1 \) so that

\[
\begin{array}{c}
\xymatrix{X \ar[dr]^{a'} \ar[d]_a & \ar[ld]_a \mathbf{Hom}_A(f, g) \ar[d]^{p_1} \ar[dl]_{p_0} \\
C & B \ar[l]_{\phi} \ar[r]_{\phi} & A \ar[r]_{f} & B}
\end{array}
\]

there exists a 2-cell \( \tau: a \Rightarrow a' \) so that

\[
\begin{array}{c}
\xymatrix{X \ar[dr]^{a'} \ar[d]_a & \ar[ld]_a \mathbf{Hom}_A(f, g) \ar[d]^{p_1} \ar[dl]_{p_0} \\
C & B \ar[l]_{\phi} \ar[r]_{\phi} & B}
\end{array}
\]

and

\[
\begin{array}{c}
\xymatrix{X \ar[dr]^{a'} \ar[d]_a & \ar[ld]_a \mathbf{Hom}_A(f, g) \ar[d]^{p_1} \ar[dl]_{p_0} \\
C & B \ar[l]_{\phi} \ar[r]_{\phi} & A \ar[r]_{f} & B}
\end{array}
\]

(iii) 2-cell conservativity: For any 2-cell

\[
\begin{array}{c}
\xymatrix{X \ar[dr]^{a'} \ar[d]_a & \ar[ld]_a \mathbf{Hom}_A(f, g) \ar[d]^{p_1} \ar[dl]_{p_0} \\
C & B \ar[l]_{\phi} \ar[r]_{\phi} & A \ar[r]_{f} & B}
\end{array}
\]

if both \( p_1 \tau \) and \( p_0 \tau \) are isomorphisms then \( \tau \) is an isomorphism.

PROOF. The cosmological functor \( \mathbf{Fun}(X, -): \mathcal{K} \to \mathbf{QCat} \) carries the pullback (3.4.2) to a pullback

\[
\begin{array}{c}
\xymatrix{\mathbf{Fun}(X, \mathbf{Hom}_A(f, g)) \ar[d]_{(p_1, p_0)} \ar[r]^{\phi} & \mathbf{Fun}(X, A)^2 \ar[d]_{(p_1, p_0)} \\
\mathbf{Fun}(X, C) \times \mathbf{Fun}(X, B) \ar[r]_{\mathbf{Fun}(X, g) \times \mathbf{Fun}(X, f)} & \mathbf{Fun}(X, A) \times \mathbf{Fun}(X, A)}
\end{array}
\]

of quasi-categories. Now Lemma 3.1.7 demonstrates that the canonical 2-cell (3.4.3) induces a natural map of hom-categories

\[
\begin{array}{c}
\xymatrix{h\mathbf{Fun}(X, \mathbf{Hom}_A(f, g)) \ar[d]_{(p_1, p_0)} \ar[r] & \mathbf{Hom}_{h\mathbf{Fun}(X, A)}(h\mathbf{Fun}(X, f), h\mathbf{Fun}(X, g)) \ar[d]_{(p_1, p_0)} \\
h\mathbf{Fun}(X, C) \times h\mathbf{Fun}(X, B) \ar[r]_{(\text{cod}, \text{dom})} &}
\end{array}
\]
over \( \text{hFun}(X, C \times B) \cong \text{hFun}(X, C) \times \text{hFun}(X, B) \) that is a smothering functor. The properties of 1-cell induction, 2-cell induction, and 2-cell conservativity follow from surjectivity on objects, fullness, and conservativity of this smothering functor respectively. 

The 1-cells \( \ast \alpha \ast : X \to \text{Hom}_A(f, g) \) that are induced by a fixed 2-cell \( \ast \alpha \ast : fb \Rightarrow gc \) are unique up to fibered isomorphism over \( C \times B \).

3.4.7. **Proposition.** Whiskering with the comma cone (3.4.3) induces a bijection between 2-cells as displayed below-left

\[
\begin{array}{c}
\begin{array}{c}
X \\
\downarrow \alpha \Rightarrow
\end{array} \quad \begin{array}{c}
A \\
\downarrow \gamma
\end{array} \\
\begin{array}{c}
C \\
\downarrow \delta
\end{array} \\
\begin{array}{c}
B
\end{array}
\end{array}
\end{array}
\]

and fibered isomorphism classes of maps of spans from \( C \) to \( B \) as displayed above-right, where the fibered isomorphisms are given by invertible 2-cells

\[
\begin{array}{c}
\begin{array}{c}
X \\
\downarrow \alpha \Rightarrow
\end{array} \quad \begin{array}{c}
A \\
\downarrow \gamma
\end{array} \\
\begin{array}{c}
C \\
\downarrow \delta
\end{array} \\
\begin{array}{c}
\text{Hom}_A(f, g)
\end{array}
\end{array}
\end{array}
\]

so that \( p_0 \gamma = \text{id}_b \) and \( p_1 \gamma = \text{id}_c \).

**Proof.** Lemma 3.1.3 proves that the fibers of the smothering functor of Proposition 3.4.6 are connected groupoids. The objects of these fiber over \( \alpha \) are functors \( X \to \text{Hom}_A(f, g) \) that whisker with the comma cone \( \phi \) to \( \alpha \), and the morphisms are invertible 2-cells that whisker with

\( (p_1, p_0) : \text{Hom}_A(f, g) \Rightarrow C \times B \)

to the identity 2-cell \( (\text{id}_c, \text{id}_b) \). The action of the smothering functor defines a bijection between the objects of its codomain and their corresponding fibers. 

The construction of the comma \( \infty \)-category is also pseudofunctorial in oplax maps op cospans defined in the homotopy 2-category:

3.4.8. **Observation.** By 1-cell induction a diagram

\[
\begin{array}{c}
\begin{array}{c}
C \\
\downarrow r
\end{array} \quad \begin{array}{c}
A \\
\downarrow p
\end{array} \\
\begin{array}{c}
\bar{C} \\
\downarrow \bar{g}
\end{array} \\
\begin{array}{c}
B
\end{array}
\end{array} \quad \begin{array}{c}
\begin{array}{c}
\downarrow f
\end{array} \quad \begin{array}{c}
\downarrow q
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
\downarrow \gamma
\end{array} \quad \begin{array}{c}
\downarrow \bar{\beta}
\end{array}
\end{array}
\end{array}
\]

\[86\]
induces a map between comma ∞-categories as displayed below-right:

that is well-defined and functorial up to fibered isomorphism; see Exercise 3.4.ii.

One of many uses of comma ∞-categories is to define the internal mapping spaces between two elements of an ∞-category $A$. This is one motivation for our notation “$\text{Hom}_A$.”

3.4.9. DEFINITION (mapping space). For any two elements $x, y: 1 \to A$ of an ∞-category $A$, their mapping space is the comma ∞-category $\text{Hom}_A(x, y)$ defined by the pullback diagram

$$
\begin{array}{ccc}
\text{Hom}_A(x, y) & \xrightarrow{\phi} & A^2 \\
(p_1, p_0) \downarrow & \searrow & \downarrow (p_1, p_0) \\
1 & \to & A \times A
\end{array}
$$

The mapping spaces in any ∞-category are discrete in the sense of Definition 1.2.26.

3.4.10. PROPOSITION (internal mapping spaces are discrete). For any pair of elements $x, y: 1 \to A$ of an ∞-category $A$, the mapping space $\text{Hom}_A(x, y)$ is discrete.

PROOF. Our task is to prove that for any ∞-category $X$, the functor space $\text{Fun}(X, \text{Hom}_A(x, y))$ is a Kan complex. This is so just when $h\text{Fun}(X, \text{Hom}_A(x, y))$ is a groupoid, i.e., when any 2-cell with codomain $\text{Hom}_A(x, y)$ is invertible. By 2-cell conservativity, a 2-cell with codomain $\text{Hom}_A(x, y)$ is invertible just when its whiskered composite with the isofibration $(p_1, p_0): \text{Hom}_A(x, y) \to 1 \times 1$ is an invertible 2-cell, but in fact this whiskered composite is an identity since $1$ is 2-terminal.

As with our convention for ∞-categories of arrows, it will be convenient to weaken the meaning of “comma ∞-category” to extend this appellation to any object of $\mathcal{K}_{/C \times B}$ that is fibered equivalent (see Definition 3.2.7) to the strict model $(p_1, p_0): \text{Hom}_A(f, g) \to C \times B$ defined by 3.4.1. This is justified because such objects satisfy the weak universal property of Proposition 3.4.6 and conversely any two objects satisfying this weak universal property are equivalent over $C \times B$. 
3.4.11. PROPOSITION (uniqueness of comma $\infty$-categories). For any isofibration $(e_1, e_0): E \to C \times B$ that is fibered equivalent to $\text{Hom}_A(f, g) \to C \times B$ the 2-cell

![Diagram](image)

encoded by the equivalence $E \simeq \text{Hom}_A(f, g)$ satisfies the weak universal property of Proposition 3.4.6. Conversely, if $(d_1, d_0): D \to C \times B$ and $(e_1, e_0): E \to C \times B$ are equipped with 2-cells

![Diagram](image)

satisfying the weak universal property of Proposition 3.4.6, then $D \simeq_{C \times B} E$.

PROOF. The proof of the first statement proceeds exactly as in the special case of Proposition 3.2.10. We prove the converse, solving Exercise 3.2.ii.

Consider a pair of 2-cells (3.4.12) satisfying the weak universal properties enumerated in Proposition 3.4.6. 1-cell induction supplies maps of spans

![Diagram](image)

with the property that $e^* \delta^* e^* = \varepsilon$ and $\delta^* e^* \delta^* = \delta$. By Proposition 3.4.7 it follows that $\delta^* \varepsilon^* \varepsilon^* \delta^* \equiv \text{id}_E$ over $C \times B$ and $\varepsilon^* \delta e^* \delta^* \equiv \text{id}_D$ over $C \times B$. This defines the data of a fibered equivalence $D \simeq E$.³

³As alluded to in Warning 3.2.9 and addressed in §3.6, there is a slight ambiguity in the 2-categorical data that encodes a fibered equivalence. Proposition 3.6.2 and Lemma 3.6.3 provide a small boost to finish this proof.

3.4.13. CONVENTION. On account of Proposition 3.4.11, we extend the appellation “comma $\infty$-category” from the strict model constructed in Definition 3.4.1 to any $\infty$-category that is fibered equivalent to it and refer to its accompanying 2-cell as the “comma cone.”

For example, in §4.3 we define the $\infty$-category of cones over a fixed diagram as a comma $\infty$-category. Proposition 3.4.11 gives us the flexibility to use multiple models for this $\infty$-category, which will be useful in characterizing the universal properties of limits and colimits.
Exercises.

3.4.i. Exercise (C.1.12). Complete the proof of Proposition 3.4.5 by observing that the map \( \text{Hom}_p(q, r) \) factors as a pullback of the Leibniz cotensor of \( \partial \Delta[1] \hookrightarrow \Delta[1] \) with \( p \) followed by a pullback of \( r \times q \).

3.4.ii. Exercise. Use Proposition 3.4.7 to justify the pseudofunctoriality of the comma construction in oplax morphisms described in Observation 3.4.8.

3.4.iii. Exercise. Exercises 3.4.i and 3.4.ii illustrate the relative advantages and disadvantages of strict simplicial and weak 2-categorical universal properties of the comma \( \infty \)-category construction: the former gives a strictly functorial action but only of strictly commutative maps of cospans, while the latter gives an action of oplax transformations of cospans that is only pseudofunctorial. Mediating between these two constructions, use Lemma 1.2.16 and Proposition 1.4.10 to rectify a pseudo-commutative diagram

\[
\begin{array}{ccc}
    C & \xrightarrow{g} & A \\
    \downarrow r & \equiv & \downarrow q \\
    \tilde{C} & \xrightarrow{\tilde{g}} & \tilde{A} \leftarrow \tilde{f} \\
\end{array}
\]

into an equivalent strictly commutative diagram and prove that the induced map \( \text{Hom}_p(q, r) \) is equivalent to \( \beta \downarrow \gamma \).

3.4.iv. Exercise. Show that the functor between comma \( \infty \)-categories induced by a diagram

\[
\begin{array}{ccc}
    C & \xrightarrow{g} & A \\
    \downarrow r & \equiv & \downarrow q \\
    \tilde{C} & \xrightarrow{\tilde{g}} & \tilde{A} \leftarrow \tilde{f} \\
\end{array}
\]

in which \( \beta \) and \( \gamma \) are isomorphisms and \( p, q, \) and \( r \) are equivalences defines an equivalence

\[
\text{Hom}_A(f, g) \xrightarrow{\beta \downarrow \gamma} \text{Hom}_{\tilde{A}}(\tilde{f}, \tilde{g})
\]

over \( r \times q \).

3.5. Representable Comma \( \infty \)-Categories

Definition 3.4.1 constructs a comma \( \infty \)-category for any cospan. Of particular importance, are the special cases of this construction where one of the legs of the cospan is an identity:
3.5.1. Definition (left and right representations). Any functor $f: A \to B$ admits a **left representation** and a **right representation** as a comma $\infty$-category, displayed below-left and below-right respectively:

$$
\begin{array}{ccc}
\Hom_B(f, B) & \xleftarrow{\phi} & A \\
p_1 & & p_0 \\
B & & f \\
\downarrow & & \downarrow \\
B & & B \\
\end{array}
\quad
\begin{array}{ccc}
\Hom_B(B, f) & \xleftarrow{\phi} & A \\
p_1 & & p_0 \\
A & & B \\
\downarrow & & \downarrow \\
B & & B \\
\end{array}
$$

To save space, we typically depict the **left comma cone** over $f$ displayed above-left and the **right comma cone** over $f$ displayed above-right as inhabiting triangles rather than squares.

By Proposition 3.4.11, the weak universal property of the comma cone characterizes the comma span up to fibered equivalence over the product of the codomain objects. Thus:

3.5.2. Definition. Given a cospan $C \xrightarrow{g} A \xleftarrow{f} B$, the comma $\infty$-category $\Hom_A(f, g) \to C \times B$ is

- **left representable** if there exists a functor $\ell: B \to C$ so that $\Hom_A(f, g) \simeq_{C \times B} \Hom_C(\ell, C)$
- **right representable** if there exists a functor $r: C \to B$ so that $\Hom_A(f, g) \simeq_{C \times B} \Hom_B(B, r)$.

In this section, we prove a useful representability theorem: demonstrating that a functor $g: C \to A$ admits an absolute right lifting along $f: B \to A$ if and only if the comma $\infty$-category $\Hom_A(f, g)$ is right representable, the representing functor then defining the postulated lifting. We prove this over the course of three theorems, each strengthening the previous statement. The first theorem characterizes 2-cells

$$
\begin{array}{c}
C \xrightarrow{r} B \\
\downarrow \Downarrow{\rho} \\
A \\
\end{array}
\xrightarrow{f}
\begin{array}{c}
B \\
\end{array}
$$

that define absolute right lifting diagrams via induced equivalences $\Hom_B(B, r) \simeq_{C \times B} \Hom_A(f, g)$ between comma $\infty$-categories. The second theorem proves that a functor $r$ defines an absolute right lifting of $g$ through $f$ just when $\Hom_A(f, g)$ is right-represented by $r$; the difference is that no 2-cell $\rho: fr \Rightarrow g$ need be provided. The final theorem gives a general right-representability criterion that can be applied to construct a right representation to $\Hom_A(f, g)$ without a priori specifying the representing functor $r$. 
3.5.3. Theorem. The triangle below-left defines an absolute right lifting diagram if and only if the induced 1-cell below-right

\[
\begin{array}{c}
C \xrightarrow{g} A \\
r \downarrow \rho \\
B \xleftarrow{f}
\end{array} \overset{\sim}{\Rightarrow} \begin{array}{c}
\Hom_B(B, r) \\
p_1 \phi \downarrow p_0 \\
\phi \downarrow p_0 \\
C \xrightarrow{g} A \xleftarrow{f} B \\
\end{array}
\]

defines a fibered equivalence \(\Hom_B(B, r) \simeq_{C \times B} \Hom_A(f, g)\).

In [119], Street and Walters interpret the equivalence \(\Hom_B(B, r) \simeq \Hom_A(f, g)\) encoding an absolute right lifting diagram as asserting that “\(f\) is left adjoint to \(r\) relative to \(g\).” This notion of relative adjunction, first studied by Ulmer [122], should be compared with the definitions of adjunction given in Lemma 2.3.6 and Proposition 4.1.1.

Proof. Suppose that \((r, \rho)\) defines an absolute right lifting of \(g\) through \(f\) and consider the unique factorization of the comma cone under \(\Hom_A(f, g)\) through \(\rho\) as displayed by the left-hand pasting equality

\[
\begin{array}{c}
\Hom_A(f, g) \\
p_1 \phi \downarrow p_0 \\
\phi \downarrow p_0 \\
C \xrightarrow{g} A \xleftarrow{f} B \\
\end{array}
\]

By 1-cell induction, the 2-cell \(\zeta\) factors through the right comma cone over \(r\) as displayed above-right. Substituting the right-hand side of (3.5.4) into the bottom portion of the above-right diagram, we see that \(yz: \Hom_A(f, g) \to \Hom_A(f, g)\) is a 1-cell that factors the comma cone for \(\Hom_A(f, g)\) through itself. Applying the universal property of Proposition 3.4.7, it follows that there is a fibered isomorphism \(yz \simeq \id_{\Hom_A(f, g)}\) over \(C \times B\).

To prove that \(zy \simeq \id_{\Hom_B(B, r)}\) it suffices to argue similarly that the right comma cone over \(r\) restricts along \(zy\) to itself. Since \((r, \rho)\) is absolute right lifting, it suffices to verify the equality \(\phi z y = \phi\)
after pasting below with \( \rho \). But now reversing the order of the equalities in (3.5.5) and (3.5.4) we have

\[
\text{Hom}_B(B, r) = \text{Hom}_A(f, g) = \text{Hom}_B(B, r)
\]

which is exactly what we wanted to show. Thus, we see that if \((r, \rho)\) is an absolute right lifting of \( g \) through \( f \), then the induced map (3.5.4) defines a fibered equivalence \( \text{Hom}_B(B, r) \cong \text{Hom}_A(f, g) \).

Now, conversely, suppose the 1-cell \( y \) defined by (3.5.4) is a fibered equivalence and let us argue that \((r, \rho)\) is an absolute right lifting of \( g \) through \( f \). By Proposition 3.4.11, via this fibered equivalence the 2-cell displayed on the left-hand side of the equality in (3.5.4) inherits the weak universal property of a comma cone from \( \text{Hom}_A(f, g) \). So Proposition 3.4.7 supplies a bijection displayed below-left

\[
\begin{align*}
\{ C & \xleftarrow{a} X \xrightarrow{b} B \\ A & \xleftarrow{g} \}
\end{align*}
\]

between 2-cells over the cospan and fibered isomorphism classes of maps of spans that is implemented, from center to left, by whiskering with the 2-cell \( pp_1 \cdot f \phi : fp_0 \Rightarrow gp_1 \) in the center of (3.5.4). Proposition 3.4.7 also applies to the right comma cone \( \phi \) over \( r : C \to B \) giving us a second bijection, displayed above center-right between the same fibered isomorphism classes of maps of spans and 2-cells over \( r \). This second bijection is implemented, from center to right, by pasting with the right comma cone \( \phi : p_0 \Rightarrow rp_1 \). Combining these yields a bijection between the 2-cells displayed on the right and the 2-cells displayed on the left implemented by pasting with \( \rho \), which is precisely the universal property that characterizes absolute right lifting diagrams.

\[\Box\]

As a special case of this result, we can now present several equivalent characterizations of fully faithful functors between \( \infty \)-categories.

3.5.6. COROLLARY. The following are equivalent, and define what it means for a functor \( k : A \to B \) between \( \infty \)-categories to be fully faithful:

\[92\]
(i) The identity defines an absolute right lifting diagram:

\[
\begin{array}{ccc}
A & \xrightarrow{k} & B \\
\downarrow & & \\
A & \xrightarrow{k} & B
\end{array}
\]

(ii) The identity defines an absolute left lifting diagram:

\[
\begin{array}{ccc}
A & \xleftarrow{k} & B \\
\downarrow & & \\
A & \xleftarrow{k} & B
\end{array}
\]

(iii) For any \(\infty\)-category \(X\) the induced functor

\[k_* : \text{hFun}(X, A) \to \text{hFun}(X, B)\]

is a fully faithful functor of 1-categories.

(iv) The functor induced by the identity 2-cell \(\text{id}_k\) is an equivalence

\[
\begin{array}{ccc}
\text{Hom}_B(k, k) & \xrightarrow{\text{id}_k} & \text{Hom}_A(f, g) \\
\downarrow & & \\
\text{Hom}_B(k, k)
\end{array}
\]

Proof. The statement (iii) is an unpacking of the meaning of both (i) and (ii). Theorem 3.5.3 specializes to prove (i) \(\iff\) (iv) or dually (ii) \(\iff\) (iv).

It is not surprising that post-composition with a fully faithful functor of \(\infty\)-categories should induce a fully-faithful functor of hom-categories in the homotopy 2-category. What is surprising is that this definition is strong enough to capture the \(\infty\)-categorical notion of fully-faithfulness. This result, together with the general case of Theorem 3.5.3 should be provide some retroactive justification for our work in the homotopy 2-category in Chapter 2.

Theorem 3.5.3 has another important consequence used already in the proof of Proposition 2.4.8.

3.5.7. Corollary. Cosmological functors preserve absolute lifting diagrams.

Proof. Consider a cosmological functor \(F : \mathcal{K} \to \mathcal{L}\) together with an absolute right lifting diagram in \(\mathcal{K}\):

\[
\begin{array}{ccc}
B & \xrightarrow{r} & A \\
\downarrow & \Downarrow{f} & \\
C & \xrightarrow{g} & A
\end{array}
\]

By Theorem 3.5.3, the induced functor of (3.5.4) defines a fibered equivalence \(y : \text{Hom}_B(B, r) \xrightarrow{\sim} \text{Hom}_A(f, g)\) over \(C \times B\).

Since cosmological functors preserve the simplicial limits and isofibrations of (3.4.2), \(F\) carries the functor \(y\) to a a functor \(Fy : \text{Hom}_{FB}(FB, Fr) \to \text{Hom}_{FA}(Ff, Fg)\) over \(FC \times FB\). By Lemma 1.3.2,
this functor is again a fibered equivalence. Since cosmological functors define 2-functors, this functor satisfies a pasting equation

\[
\begin{array}{c}
\text{Hom}_{FB}(FB, Fr) \\
p_1 \quad Ff \quad p_0 \\
FC \quad r \quad FB \\
Fg \quad F\phi \quad FA
\end{array}
\quad = 
\begin{array}{c}
\text{Hom}_{FA}(Ff, Fg) \\
p_1 \quad \vdash Ff \quad p_0 \\
FC \quad F\phi \quad FB \\
Fg \quad f \quad FA
\end{array}
\]

in \(\mathcal{L}\). By Theorem 3.5.3, this fibered equivalence witnesses the fact that

\[
\begin{array}{c}
FB \\
r \quad f \\
FC \quad Fr \quad FA
\end{array}
\]

defines an absolute right lifting diagram in \(\mathcal{L}\). The proof for absolute left lifting diagrams is similar. \(\square\)

Having proven Theorem 3.5.3 our immediate aim is to strengthen it to show that a fibered equivalence \(\text{Hom}_B(B, r) \cong_{C \times B} \text{Hom}_A(f, g)\) implies that \(r : C \to B\) defines an absolute right lifting of \(g\) through \(f\) without a previously specified 2-cell \(\rho : fr \Rightarrow g\).

3.5.8. Theorem. Given a trio of functors \(r : C \to B, f : B \to A,\) and \(g : C \to A\) there is a bijection between 2-cells as displayed below-left and fibered isomorphism classes of maps of spans as displayed below-right

\[
\begin{array}{c}
\left\{ \begin{array}{c}
\text{r} \\
\text{\rho} \\
\text{f} \\
\text{C} \quad \text{B} \\
\overline{g} \quad \overline{\text{A}}
\end{array} \right\} \iff \left\{ \begin{array}{c}
\text{Hom}_B(B, r) \\
p_1 \quad p_0 \\
C \quad \vdash B \\
\text{Hom}_A(f, g) \\
p_1 \quad p_0 \\
\text{A} \quad \text{B}
\end{array} \right\}
\end{array}
\]
that is constructed by pasting with the right comma cone over \( r \) and then applying 1-cell induction to factor through the comma cone for \( \text{Hom}_A(f, g) \)

Moreover, a 2-cell \( \rho : f \Rightarrow g \) displays \( r \) as an absolute right lifting of \( g \) through \( f \) if and only if the corresponding map of spans \( y : \text{Hom}_B(B, r) \to \text{Hom}_A(f, g) \) is an equivalence.

The second clause is the statement of Theorem 3.5.3, so it remains only to prove the first. We show the claimed construction is a bijection by exhibiting its inverse, the construction of which involves a rather mysterious lemma whose significance will gradually become apparent. For instance, Lemma 3.5.9 figures prominently in the proof of the external Yoneda lemma in §?? and is also the main ingredient in a “cheap” version of the Yoneda lemma appearing as Corollary 3.5.11.

3.5.9. Lemma. Consider the right comma cone over any functor \( f : A \to B \)

Then the codomain-projection functor \( p_1 : \text{Hom}_B(B, f) \to A \) admits a right adjoint right inverse \( i \) induced from the identity 2-cell \( \text{id}_f \), defining an adjunction

over \( A \) whose counit is an identity and whose unit \( \eta : \text{id} \Rightarrow ip_1 \) satisfies the conditions \( \eta i = \text{id}_i \), \( p_1 \eta = \text{id}_{p_1} \) and \( p_0 \eta = \phi \).

\(^4\)A functor admits a right adjoint right inverse just when it is the left adjoint in an adjunction whose counit is invertible; see §B.4. When the original functor is an isofibration, as is the case here, any right adjoint right inverse adjunction can be upgraded to one in which the counit is an identity, which can then be upgraded further to a fibered adjunction; see Definition 3.6.5 and Lemma 3.6.8.
**Proof.** This adjunction is constructed via the weak universal properties of the right comma cone over $f$. The identity 2-cell $id_f$ induces a 1-cell over the right comma cone over $f$:

Note that $p_1i = id_A$, so we may take the counit to be the identity 2-cell. Since $\phi i = id_f$, we have a pasting equality:

which allows us to induce a 2-cell $\eta: id \Rightarrow ip_1$ with defining equations $p_1 \eta = id_{p_1}$ and $p_0 \eta = \phi$. The first of these conditions provides one triangle equality; for the other, we must verify that $\eta i = id_i$. By 2-cell conservativity, $\eta i$ is an isomorphism since $p_1 \eta i = id_{p_1}$ and $p_0 \eta i = \phi i = id_f$ are both invertible. By naturality of whiskering, we have

and since $p_1 \eta = id_{p_1}$ the bottom edge is an identity. So $\eta i \cdot \eta i = \eta i$ and since $\eta i$ is an isomorphism cancelation implies that $\eta i = id_i$ as required. □

One interpretation of Lemma 3.5.9 is best revealed through a special case:

3.5.10. **Corollary.** For any element $b: 1 \to B$, the identity at $b$ defines a terminal element in $\text{Hom}_B(B, b)$.

**Proof.** By Lemma 3.5.9, the codomain-projection from the right representation of any functor admits a right adjoint right inverse induced from its identity 2-cell. In this case, the codomain-projection is the unique functor $!: \text{Hom}_B(B, b) \to 1$, so by Definition 2.2.1, this right adjoint identifies a terminal element of $\text{Hom}_B(B, b)$ corresponding to the identity morphism $id_b$ in the homotopy category $hB$. □

The general version of Lemma 3.5.9 has a similar interpretation to be made precise in Corollary 3.6.9: in the sliced $\infty$-cosmos $\mathcal{K}_A$, the identity functor at $A$ defines the terminal object, and Lemma 3.5.9 asserts that $id_f$ induces a terminal element of $\text{Hom}_B(B, f)$ “over $A$.”

96
Proof of Theorem 3.5.8. The inverse to the function that takes a 2-cell \(fr \Rightarrow g\) and produces an isomorphism class of maps \(\text{Hom}_B(B, r) \rightarrow \text{Hom}_A(f, g)\) over \(C \times B\) is constructed by applying Lemma 3.5.9 to the functor \(r: C \rightarrow B\): given a map \(\text{Hom}_B(B, r) \rightarrow \text{Hom}_A(f, g)\), restrict along the right adjoint \(i: C \rightarrow \text{Hom}_B(B, r)\) and paste with the comma cone for \(\text{Hom}_A(f, g)\) to define a 2-cell \(fr \Rightarrow g\).

Starting from a 2-cell \(\rho: fr \Rightarrow g\), the composite of these two functions constructs the 2-cell displayed below-left:

\[
\begin{array}{ccccccccc}
C & \xrightarrow{p_1} & \text{Hom}_B(B, r) & \xrightarrow{r} & A & \xrightarrow{g} & B \\
\downarrow{i} & & \downarrow{\phi} & & \downarrow{\phi} \\
C & \xrightarrow{p_1} & \text{Hom}_A(f, g) & \xrightarrow{p_0} & A & \xrightarrow{f} & B \\
\end{array}
\]

which equals the above-center pasted composite by the definition of \(y\) from \(\rho\), and equals the above-right composite since \(\phi i = \text{id}_r\). Thus, when a 2-cell \(\rho: fr \Rightarrow g\) is encoded as a map \(y: \text{Hom}_B(B, r) \rightarrow \text{Hom}_A(f, g)\) over \(C \times B\), and then re-converted into a 2-cell, the original 2-cell \(\rho\) is recovered.

For the converse, starting with a map \(z: \text{Hom}_B(B, r) \rightarrow \text{Hom}_A(f, g)\) over \(C \times B\), the composite of these two functions constructs an isomorphism class of maps of spans \(w\) displayed below-left by applying 1-cell induction for the comma cone for \(\text{Hom}_A(f, g)\) to the composite 2-cell pasted below-center-left:

\[
\begin{array}{ccccccccc}
C & \xrightarrow{p_1} & \text{Hom}_B(B, r) & \xrightarrow{r} & A & \xrightarrow{g} & B \\
\downarrow{i} & & \downarrow{\phi} & & \downarrow{\phi} \\
C & \xrightarrow{p_1} & \text{Hom}_A(f, g) & \xrightarrow{p_0} & A & \xrightarrow{f} & B \\
\end{array}
\]

Applying Lemma 3.5.9, there exists a 2-cell \(\eta: \text{id} \Rightarrow ip_1\) so that \(p_0\eta = \phi\) — this gives the pasting equality above center — and \(p_1\eta = \text{id}\) — which gives the pasting equality above right. Proposition 3.4.7 now implies that \(w \cong z\) over \(C \times B\). □
A dual version of Theorem 3.5.8 represents 2-cells \( g \Rightarrow f \ell \) as fibered isomorphism classes of maps \( \text{Hom}_B(\ell, B) \to \text{Hom}_A(g, f) \) over \( B \times C \). Specializing these results to the case where one of \( f \) or \( g \) is the identity, we immediately recover a “cheap” form of the Yoneda lemma:

3.5.11. **Corollary.** Given a parallel pair of functors, \( f, g : A \to B \), there are bijections between 2-cells as displayed below-center and fibered isomorphism classes of maps between their left and right representations as comma \( \infty \)-categories, as displayed below-left and below-right, respectively:

\[
\begin{align*}
\begin{array}{c}
\text{Hom}_B(g, B) \\
B \xleftarrow{p_0} \xrightarrow{p_1} A \\
\Downarrow \phi \quad \xleftarrow{\Downarrow \alpha} \\
\end{array} \\
\begin{array}{c}
\text{Hom}_B(f, B) \\
B \xleftarrow{p_0} \xrightarrow{p_1} A \\
\Downarrow \phi \quad \xleftarrow{\Downarrow \alpha} \\
\end{array}
\end{align*}
\]

that are constructed by pasting with the left comma cone over \( g \) and right comma cone over \( f \), respectively:

\[
\begin{align*}
\begin{array}{c}
\text{Hom}_B(B, f) \\
A \xleftarrow{\Downarrow \alpha} \xrightarrow{\Downarrow \alpha^*} \text{Hom}_B(B, g) \\
\Downarrow \phi \quad \xleftarrow{\Downarrow \phi^*} \\
\end{array}
\end{align*}
\]

and then applying 1-cell induction to factor through the left comma cone over \( f \) in the former case or the right comma cone over \( g \) in the latter. □

Combining the results of this section, we prove one final representability theorem that allows us to recognize when a comma \( \infty \)-category is right representable in the absence of a predetermined representing functor. This result specializes to give existence theorems for adjoint functors and for limits and colimits in the next chapter.

3.5.12. **Theorem.** The comma \( \infty \)-category \( \text{Hom}_A(f, g) \) associated to a cospan \( C \xrightarrow{g} A \xleftarrow{f} B \) is right representable if and only if its codomain-projection functor admits a right adjoint right inverse

\[
\begin{align*}
\begin{array}{c}
\text{Hom}_A(f, g) \\
C \xleftarrow{i} \xrightarrow{p_0} B \\
\Downarrow \phi \quad \xleftarrow{\Downarrow \phi^*} \\
\end{array}
\end{align*}
\]

in which case the composite \( p_0 i : C \to B \) defines the representing functor and the 2-cell represented by the functor \( i : C \to \text{Hom}_A(f, g) \) defines an absolute right lifting of \( g \) through \( f \).

**Proof.** If \( \text{Hom}_A(f, g) \) is represented on the right by a functor \( r : C \to B \), then \( \text{Hom}_A(f, g) \approx_{\text{Sets}} \text{Hom}_B(B, r) \) and thus \( p_1 : \text{Hom}_A(f, g) \to C \) is equivalent to \( p_1 : \text{Hom}_B(B, r) \to C \), which admits a right adjoint right inverse \( i \) by Lemma 3.5.9. By Proposition 2.1.13, it follows that \( p_1 : \text{Hom}_A(f, g) \to C \) admits a right adjoint right inverse as well. Note by the constructions given in these proofs that \( r = p_0 i \).

\[\text{By Proposition 2.1.10 and Exercise 2.3.vi it follows that any right adjoint } i \text{ to } p_1 \text{ will have the property that } (p_0 i, \phi i) \text{ defines an absolute right lifting of } g \text{ through } f.\]
and also that $i$ represents an absolute right lifting diagram, by Theorem 3.5.3. Thus, it remains only to prove the converse.

To that end, suppose we are given a right adjoint right inverse adjunction $p_1 \dashv i$. Unpacking the definition, this provides an adjunction

\[
\begin{array}{ccc}
C & \perp & \text{Hom}_A(f, g) \\
\text{i} & \downarrow & \downarrow p_1 \\
C & \rightarrow & C
\end{array}
\]

over $C$ whose counit is an identity and whose unit $\eta$: $\text{id} \Rightarrow ip_1$ satisfies the conditions $\eta i = \text{id}_i$ and $p_1 \eta = \text{id}_{p_1}$. By Theorem 3.5.8, to construct the fibered equivalence $\text{Hom}_B(B, r) \simeq_{\text{C\times B}} \text{Hom}_A(f, g)$ with $r := p_0 i$, it suffices to demonstrate that the 2-cell defined by restricting the comma cone for $\text{Hom}_A(f, g)$ along $i$

\[
\begin{array}{ccc}
C & \rightarrow & \text{Hom}_A(f, g) \\
\text{i} & \downarrow & \downarrow p_1 \\
C & \rightarrow & C
\end{array}
\]

defines an absolute right lifting diagram.

By 1-cell induction any 2-cell $\chi$ as displayed below-left induces a 1-cell $\text{r} \chi$ as displayed below-center:

\[
\begin{array}{ccc}
X & \rightarrow & B \\
\downarrow c & \text{r} \chi & \downarrow f \\
C & \rightarrow & A
\end{array}
\]

\[
\begin{array}{ccc}
X & \rightarrow & \text{Hom}_A(f, g) \\
\text{r} \chi & \downarrow p_0 \\
\text{r} \chi & \rightarrow & B
\end{array}
\]

\[
\begin{array}{ccc}
X & \rightarrow & \text{Hom}_A(f, g) \\
\eta i & \downarrow \text{p}_1 \\
\text{r} \chi & \rightarrow & B
\end{array}
\]

\[
\begin{array}{ccc}
X & \rightarrow & \text{Hom}_A(f, g) \\
\eta & \downarrow \text{p}_0 \\
\text{r} \chi & \rightarrow & B
\end{array}
\]

Inserting the triangle equality $p_1 \eta = \text{id}_{p_1}$ as displayed above-right constructs the desired factorization $p_0 \eta \text{r} \chi^*$: $b \Rightarrow \text{rc}$ of $\chi$ through $\phi i$.

In fact, given any 2-cell $\tau_0$: $b \Rightarrow \text{rc}$ that defines a factorization of $\chi$: $fb \Rightarrow gc$ through $\phi i$, the pair $(\tau_0, \text{id}_c)$ satisfies the compatibility condition of Proposition 3.4.6(ii), inducing a 2-cell $\tau$: $m \Rightarrow ic$ so that $\tau_0 = p_0 \tau$ and $\text{id}_c = p_1 \tau$. We'll argue that the 2-cell $\tau$ is unique, proving that the factorization $p_0 \tau$: $b \Rightarrow \text{rc}$ is also unique.

To see this, note that the adjunction $p_1 \dashv i$ over $C$ exhibits the right adjoint as a terminal element of the object $p_1$: $\text{Hom}_A(f, g) \rightarrow C$ in the strict slice of the homotopy 2-category over $C$.* It follows, as in Lemma 2.2.5, that for any object $c$: $X \rightarrow C$ and any morphism $m$: $X \rightarrow \text{Hom}_A(f, g)$ over $C$, there

*An object is a functor of $\infty$-categories $c$: $X \rightarrow C$, a 1-cell is a functor between the domain $\infty$-categories defining a strictly commutative triangle, and a 2-cell is a natural transformation between such functors that whiskers to define an identity 2-cell with codomain $C$. 

99
exists a unique 2-cell $m \Rightarrow ic$ over $C$. Thus, there is a unique 2-cell $\tau : m \Rightarrow ic$ with the property that $p_1 \tau = id_c$, and so the factorization $p_0 \tau : b \Rightarrow rc$ of $\chi$ through $\phi i$ must also be unique.

In the next section, we will learn how to express Theorem 3.5.12 more concisely as the assertion that a comma $\infty$-category $Hom_A(f, g)$ is right representable just when its codomain-projection functor $p_1 : Hom_A(f, g) \to C$ admits a terminal element as an object of the sliced $\infty$-cosmos $K_{/C}$; see Corollary 3.6.9. Dually, $Hom_A(f, g)$ is left representable just when its domain-projection functor admits an initial element as an object of the sliced $\infty$-cosmos $K_{/B}$. There is a small gap between this statement and the version proven in Theorem 3.5.12 having to do with the discrepancy between the homotopy 2-category of the sliced $\infty$-cosmos $K_{/C}$ and the slice of the homotopy 2-category $bK$ over $C$. This is the subject to which we now turn.

Exercises.

3.5.i. EXERCISE. Anticipate Proposition 4.1.1 by exploring how one might encode the existence of an adjunction $f \dashv u$ between a given opposing pair of functors using comma $\infty$-categories.

3.5.ii. EXERCISE. Extend the result of Exercise 2.3.vi to show that for any equivalence of cospans

$$
\begin{array}{ccc}
C & \xrightarrow{g} & A & \xleftarrow{f} & B \\
\downarrow \cong & & \downarrow \cong & & \downarrow \\
C & \xrightarrow{\bar{g}} & \bar{A} & \xleftarrow{\bar{f}} & \bar{B}
\end{array}
$$

there exists an absolute right lifting of $g$ through $f$ if and only if there exists an absolute right lifting of $\bar{g}$ through $\bar{f}$.

3.5.iii. EXERCISE ([120, 3.7]). Use Theorem 3.5.3 and Corollary 3.5.6(iv) to prove that a fully faithful functor $f : A \to B$ reflects all limits or colimits that exist in $A$. Why does this argument not also show that $f : A \to B$ preserves them?

3.6. Smothering 2-Functors and Fibered Equivalences

In Proposition 3.2.10, we discovered that the $\infty$-category $A^2$ of arrows in $A$ together with its codomain- and domain-evaluation functors $(p_1, p_0) : A^2 \to A \times A$ satisfies a weak universal property in the homotopy 2-category that characterizes it up to equivalence over $A \times A$. Similarly, Proposition 3.4.11 tells us that the comma $\infty$-category associated to a given pair of functors with common codomain is characterized up to fibered equivalence, as defined in Definition 3.2.7.

As noted in Warning 3.2.9 there is some ambiguity regarding the 2-categorical data required to specify a fibered equivalence, that we shall now address head-on. The issue is that, for an $\infty$-category $B$ in an $\infty$-cosmos $K$, the homotopy 2-category $b(K_{/B})$ is not isomorphic to the 2-category $(bK)_{/B}$ of isofibrations, functors, and 2-cells over $B$ in the homotopy 2-category $bK$ of $K$; see Exercise 1.4.viii.

However, there is a canonical comparison functor relating this pair of 2-categories that satisfies a property we now introduce:

3.6.1. DEFINITION (smothering 2-functor). A 2-functor $F : \mathcal{A} \to \mathcal{B}$ is smothering if it is

- surjective on objects;
• full on 1-cells: for any pair of objects $A, A'$ in $\mathcal{A}$ and 1-cell $k: FA \to FA'$ in $\mathcal{B}$, there exists $f: A \to A'$ in $\mathcal{A}$ with $Ff = k$;

• full on 2-cells: for any parallel pair $f, g: A \to A'$ in $\mathcal{A}$ and 2-cell $\beta: FA \Rightarrow FA'$ in $\mathcal{B}$, there exists a 2-cell $\alpha: f \Rightarrow g$ in $\mathcal{A}$ with $F\alpha = \beta$; and

• conservative on 2-cells: for any 2-cell $\alpha$ in $\mathcal{A}$ if $F\alpha$ is invertible in $\mathcal{B}$ then $\alpha$ is invertible in $\mathcal{A}$.

This is to say, a smothering 2-functor is a surjective-on-objects 2-functor that is “locally smothering,” meaning that the action on hom-categories is by a smothering functor, as codified in Definition 3.1.2.

The prototypical example of a smothering 2-functor solves Exercise 1.4.viii.

3.6.2. PROPOSITION. Let $B$ be an $\infty$-category in an $\infty$-cosmos $\mathcal{K}$. There is a canonical 2-functor

$$h(\mathcal{K}_B / B) \to (h\mathcal{K})_B$$

from the homotopy 2-category of the sliced $\infty$-cosmos $\mathcal{K}_B / B$ to the 2-category of isofibrations, functors, and 2-cells over $B$ in $h\mathcal{K}$ and this 2-functor is smothering.

This follows more-or-less immediately from Lemma 3.1.5 but we spell out the details nonetheless.

PROOF. The 2-categories $h(\mathcal{K}_B)$ and $(h\mathcal{K})_B$ have the same objects — isofibrations with codomain $B$ — and the same 1-cells — functors between the domains that commute with these isofibrations to $B$ — so the canonical mapping may be defined to act as the identity on underlying 1-categories.

By the definition of the sliced $\infty$-cosmos given in Proposition 1.2.22, a 2-cell between functors $f, g: E \to F$ from $p: E \to B$ to $q: F \to B$ is a homotopy class of 1-simplices in the quasi-category defined by the pullback of simplicial sets below-left

$\begin{array}{ccc}
\text{Fun}_B(E, F) & \xrightarrow{\beta} & \text{Fun}(E, F) \\
\downarrow \alpha & & \downarrow q_\ast \\
\mathbb{1} & \xrightarrow{p} & \text{Fun}(E, B)
\end{array}$

$\begin{array}{ccc}
(h\text{Fun})_B(E, F) & \xrightarrow{\beta} & h\text{Fun}(E, F) \\
\downarrow \alpha & & \downarrow q_\ast \\
\mathbb{1} & \xrightarrow{p} & h\text{Fun}(E, B)
\end{array}$

Unpacking, a 2-cell $\alpha: f \Rightarrow g$ is represented by a 1-simplex $\alpha: f \to g$ in $\text{Fun}(E, F)$ that whiskers with $q$ to the degenerate 1-simplex on the vertex $p \in \text{Fun}(E, B)$, and two such 1-simplices represent the same 2-cell if and only if they bound a 2-simplex of the form displayed in (1.1.8) that also whiskers with $q$ to the degenerate 2-simplex on $p$.

By contrast, a 2-cell in $(h\mathcal{K})_B$ is a morphism in the category defined by the pullback of categories above-right. Such 2-cells are represented by 1-simplices $\alpha: f \to g$ in $\text{Fun}(E, F)$ that whisker with $q$ to 1-simplices in $\text{Fun}(E, B)$ that are homotopic to the degenerate 1-simplex on $p$, and two such 1-simplices represent the same 2-cell if and only if they are homotopic in $\text{Fun}(E, F)$.

Applying the homotopy category functor $h: Q\text{Cat} \to \text{Cat}$ to the above-left pullback produces a cone over the above-right pullback, inducing a canonical map

$$h(\text{Fun}_B(E, F)) \to (h\text{Fun})_B(E, F),$$

which is the action on hom-categories of the canonical 2-functor $h(\mathcal{K}_B) \to (h\mathcal{K})_B$.

The 2-functor just constructed is bijective on 0- and 1-cells. To see that it is full on 2-cells we must show that any 1-simplex $\alpha: f \to g$ in $\text{Fun}(E, F)$, for which $q\alpha: p \to p$ is homotopic to $p \cdot \sigma^0: p \to p$
in \( \text{Fun}(E, B) \), is homotopic in \( \text{Fun}(E, F) \) to a 1-simplex from \( f \) to \( g \) over \( p \cdot \sigma^0 \). By Lemma 1.1.9, any such \( \alpha \) defines a lifting problem

\[
\begin{array}{ccc}
\Lambda^1[2] & \to & \text{Fun}(E, F) \\
\downarrow & & \downarrow q^* \\
\Delta[2] & \to & \text{Fun}(E, B)
\end{array}
\]

A solution exists since by axiom 1.2.1(ii) \( q_* : \text{Fun}(E, F) \to \text{Fun}(E, B) \) is an isofibration, proving that \( h(K_B) \to (hK)_B \) is full on 2-cells.

Now suppose \( \alpha : f \to g \) represents a 2-cell in \( \text{Fun}_B(E, F) \) whose image in \( (h\text{Fun})_B(E, F) \) is an isomorphism. A map in a 1-category defined by a pullback is invertible if and only if its projections along the legs of the pullback cone are isomorphisms. Thus the image of \( \alpha \) is invertible if and only if \( \alpha : f \to g \) defines an isomorphism in \( h\text{Fun}(E, F) \), which by Definition 1.1.13 is the case if and only if \( \alpha : f \to g \) represents an isomorphism in \( \text{Fun}(E, F) \). Since \( \alpha \) is fibered over the degenerate 1-simplex at \( p \), this presents us with a lifting problem

\[
\begin{array}{ccc}
\mathbb{2} & \to & \text{Fun}_B(E, F) \\
\downarrow & & \downarrow q^* \\
\mathbb{1} & \to & \text{Fun}(E, B)
\end{array}
\]

which Exercise 1.1.vi tells us we can solve. This proves that \( h(K_B) \to (hK)_B \) reflects invertibility of 2-cells and hence defines a smothering 2-functor.

Smothering 2-functors are not strictly speaking invertible, but nevertheless 2-categorical structures from the codomain can be lifted to the domain:

3.6.3. LEMMA. Smothering 2-functors reflect equivalences: for any smothering 2-functor \( F : \mathcal{A} \to \mathcal{B} \) and 1-cell \( f : A \to B \) in \( \mathcal{A} \), if \( Ff : FA \Rightarrow FB \) is an equivalence in \( \mathcal{B} \) then \( f \) is an equivalence in \( \mathcal{A} \).

PROOF. By fullness on 1-cells, an equivalence inverse \( g' : FB \Rightarrow FA \) to \( Ff \) lifts to a 1-cell \( g : B \to A \) in \( \mathcal{A} \). By fullness on 2-cells, the isomorphisms \( \text{id}_{FA} \cong g' \circ Ff \) and \( Ff \circ g' \cong \text{id}_{FB} \) also lift to \( \mathcal{A} \) and by conservativity on 2-cells these lifted 2-cells are also invertible.

Applying Lemma 3.6.3 to the smothering 2-functor

\[ h(K_B) \to (hK)_B \]

we resolve the ambiguity about the 2-categorical data of a fibered equivalence.

3.6.4. PROPOSITION (fibered equivalence data).

(i) Any equivalence in \( (hK)_B \) lifts to an equivalence in \( h(K_B) \). That is, fibered equivalences over \( B \) may be specified by defining an opposing pair of 1-cells \( f : E \to F \) and \( g : F \to E \) over \( B \) together with invertible 2-cells \( \text{id}_E \cong gf \) and \( fg \cong \text{id}_F \) that lie over \( B \) in \( hK \).

(ii) Moreover, if \( f : E \to F \) is a map between isofibrations over \( B \) that admits an not-necessarily fibered equivalence inverse \( g : F \to E \) with not-necessarily fibered 2-cells \( \text{id}_E \cong gf \) and \( fg \cong \text{id}_F \), then this data is isomorphic to a genuine fibered equivalence.
Proof. The first statement is proven by Lemma 3.6.3 and Proposition 3.6.2. The second statement asserts that the forgetful 2-functor \( (\mathcal{K})_B \to \mathcal{K} \) reflects equivalences. Exercise 3.6.i shows that for any map between isofibrations over \( B \) that admits an equivalence inverse in the underlying 2-category, the inverse equivalence and invertible 2-cells can be modified to also lie over \( B \). □

This gives a 2-categorical proof of Proposition 1.2.22(vii), that for any \( \infty \)-category \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \), the forgetful functor \( \mathcal{K}_B \to \mathcal{K} \) preserves and reflects equivalences.

The smothering 2-functor \( \mathfrak{h}(\mathcal{K})_B \to (\mathfrak{h}\mathcal{K})_B \) can also be used to lift adjunctions that are fibered 2-categorically over \( B \) to adjunctions in the sliced \( \infty \)-cosmos \( \mathcal{K}/B \).

3.6.5. Definition (fibered adjunction). A fibered adjunction over an \( \infty \)-category \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \) is an adjunction

\[
\begin{array}{ccc}
E & \xleftarrow{f} & F \\
\downarrow{u} & & \downarrow{u} \\
B & & B
\end{array}
\]

in the sliced \( \infty \)-cosmos \( \mathcal{K}/B \). We write \( f \dashv_B u \) to indicate that specified functors over \( B \) are adjoint over \( B \).

3.6.6. Lemma (pullback and projection of fibered adjunctions).

(i) A fibered adjunction over \( B \) can be pulled back along any functor \( k : A \to B \) to define a fibered adjunction over \( A \).

(ii) A fibered adjunction over \( A \) can be composed with any isofibration \( p : A \to B \) to define a fibered adjunction over \( B \).

Proof. By Proposition 1.3.3(v), pullback defines a cosmological functor \( k^* : \mathcal{K}/B \to \mathcal{K}/A \), which descends to a 2-functor \( \mathfrak{h}(\mathcal{K}/B) \to \mathfrak{h}(\mathcal{K}/A) \) that carries fibered adjunctions over \( B \) to fibered adjunctions over \( A \). This proves (i).

Composition with an isofibration \( p : A \to B \) also defines a 2-functor \( p^* : \mathfrak{h}(\mathcal{K}/A) \to \mathfrak{h}(\mathcal{K}/B) \); the reason we ask \( p \) to be an isofibration is due to our convention that the objects in sliced \( \infty \)-cosmos are isofibrations over a fixed base. Thus, composition with an isofibration carries a fibered adjunction over \( A \) to a fibered adjunction over \( B \) proving (ii). □

In analogy with Lemma 3.6.3:

3.6.7. Lemma. If \( F \) : \( \mathcal{A} \to \mathcal{B} \) is a smothering 2-functor, then any adjunction in \( \mathcal{B} \) may be lifted to an adjunction in \( \mathcal{A} \). In particular, any adjunction in the slice 2-category \((\mathfrak{h}\mathcal{K})/B\) of an \( \infty \)-cosmos \( \mathcal{K} \) lifts to a fibered adjunction over \( B \).

Proof. Exercise 3.6.iii. □

Fibered adjunctions frequently arise as right adjoint right inverses or left adjoint right inverses to a given isofibration. The next result shows that whenever an isofibration \( p : E \to B \) admits a right adjoint right inverse, then its right adjoint may be modified so that the invertible counit becomes an identity, and this adjunction may then be lifted to a fibered adjunction over \( B \). The dual also holds:
3.6.8. **Lemma.** Let \( p : E \rightarrow B \) be any isofibration that admits a right adjoint right inverse \( r' : B \rightarrow E \). Then \( r' \) is isomorphic to a functor \( r \) that defines a fibered adjunction:

\[
\begin{array}{c}
E \\
\downarrow p \\
B \\
\end{array}
\quad \begin{array}{c}
\downarrow r' \\
\downarrow \gamma \quad \gamma \in B \\
\end{array}
\quad \begin{array}{c}
E \\
\downarrow p \\
B \\
\end{array}
\]

**Proof.** Since an isofibration \( p : E \rightarrow B \) in an \( \infty \)-cosmos \( \mathcal{K} \) defines an isofibration in the homotopy 2-category \( \mathcal{K} \), the invertible counit \( \epsilon' : pr' \cong id_B \) of the adjunction \( p \dashv r' \) lifts to define a functor \( r : B \rightarrow E \) together with a natural isomorphism \( \gamma : r' \cong r \) so that \( p\gamma = \epsilon' \) and \( pr = id_B \):

\[
\begin{array}{c}
B \\
\downarrow p \\
B \\
\end{array}
\quad \begin{array}{c}
\downarrow \gamma \\
\downarrow r \\
B \\
\end{array}
\quad \begin{array}{c}
E \\
\downarrow p \\
B \\
\end{array}
\]

By the construction left to the reader in Exercise 2.1.ii, \( p \dashv r \) with unit \( \eta := \gamma p \cdot \eta' \) defined by composing the original unit \( \eta' \) with \( \gamma \) and with counit \( \epsilon := \epsilon' \cdot py^{-1} \). In particular, since \( p\gamma = \epsilon \), the counit is the identity 2-cell, and consequently one of the triangle equality composites reduces to the assertion that \( p\eta = id_B \).

This constructs a right adjoint to \( p \) considered as a functor in \( (\mathcal{K})/B \). By Lemma 3.6.7, this lifts along the smothering 2-functor of Proposition 3.6.2 to define a fibered adjunction over \( B \).

Since the identity on \( B \) defines the terminal object of the sliced \( \infty \)-cosmos \( \mathcal{K}_B \), Lemma 3.6.8 can be summarized more compactly as follows:

3.6.9. **Corollary.** An isofibration \( p : E \rightarrow B \) in \( \mathcal{K} \) admits a right adjoint right inverse if and only if it admits a terminal element as an object of \( \mathcal{K}_B \). Dually, \( p : E \rightarrow B \) admits a left adjoint right inverse if and only if it admits an initial element as an object of \( \mathcal{K}_B \). □

3.6.10. **Example.** Lemma 3.5.9 constructs an adjunction in the sliced 2-category \( (\mathcal{K})/A \). Lemma 3.6.7 now allows us to lift it to a genuine fibered adjunction

\[
\begin{array}{c}
A \\
\downarrow i \\
A \\
\end{array}
\quad \begin{array}{c}
\downarrow p_1 \\
\downarrow p_1 \\
A \\
\end{array}
\quad \begin{array}{c}
\downarrow p_1 \\
\downarrow p_1 \\
A \\
\end{array}
\]

in the sliced \( \infty \)-cosmos \( \mathcal{K}_A \). By Corollary 3.6.9 this situation may be summarized by saying that \( p_1 : \text{Hom}_B(B, f) \rightarrow A \) admits a terminal element over \( A \).

By Lemma 3.6.6(i), we may pull back the fibered adjunction along any element \( a : 1 \rightarrow A \) to obtain an adjunction

\[
\begin{array}{c}
1 \\
\downarrow i_a \\
1 \\
\end{array}
\quad \begin{array}{c}
\downarrow ! \\
\downarrow ! \\
1 \\
\end{array}
\quad \begin{array}{c}
\downarrow i_a \\
\downarrow i_a \\
1 \\
\end{array}
\]

104
that identifies a terminal element in the fiber $\text{Hom}_B(B, fa)$ of $p_1 : \text{Hom}_B(B, f) \to A$ over $a$, generalizing the result of Corollary 3.5.10.

3.6.11. **Example** (the fibered adjoints to composition). For any $\infty$-category $A$, the adjoints to the “composition” functor $\circ : A^2 \times A^2 \to A^2$ constructed in Lemma 2.1.14 may be constructed by composing a triple of adjoint functors that are fibered over the endpoint-evaluation functors

$$
\begin{array}{c}
1 + 1 \\
\downarrow s^0 \\
A^3
\end{array}
\quad \quad \quad
\begin{array}{c}
A^3 \\
\downarrow p_{2,0} \\
A \times A
\end{array}
\quad \quad \quad
\begin{array}{c}
A^3 \\
\downarrow p_{1,0} \\
A \times A
\end{array}
$$

with an adjoint equivalence involving a functor $A^3 \Rightarrow A^2 \times A^2$, which also lies over $A \times A$. Lemma 3.6.8 and its dual implies that these adjoint equivalences can be lifted from to fibered adjoint equivalences over $A \times A$, and now both adjoint triples and hence also the composite adjunctions

$$
\begin{array}{c}
A^2 \times A^2 \\
\downarrow (\cdot, \text{id}_{\text{dom}(\cdot)}) \\
A^2
\end{array}
\quad \quad \quad
\begin{array}{c}
A^2 \\
\downarrow (\text{id}_{\text{col}(\cdot)}, \cdot) \\
A \times A
\end{array}
$$

lie in $\mathcal{K}_{A \times A}$.

This fibered adjunction, which allows us to work at the $\infty$-cosmos level rather than purely in the homotopy 2-category, figures in the proof of a result that will allow us to convert limit and colimit diagrams into right and left Kan extension diagrams in the next chapter.

3.6.12. **Proposition.** A cospan as displayed below-left admits an absolute right lifting if and only if the cospan displayed below-right admits an absolute $f$ right lifting

$$
\begin{array}{c}
B \\
\downarrow r
\end{array}
\quad \quad \quad
\begin{array}{c}
\text{Hom}_A(f, A) \\
\downarrow \epsilon
\end{array}
\quad \quad \quad
\begin{array}{c}
C \\
\downarrow g
\end{array}
$$

in which case the 2-cell $\epsilon$ is necessarily an isomorphism and the pair $(i, \epsilon)$ can be chosen to be $((p^\gamma, \text{id})$.

**Proof.** By Theorem 3.5.12, a cospan in an $\infty$-cosmos $\mathcal{K}$ admits an absolute right lifting if and only if the codomain-projection functor from the associated comma $\infty$-category admits a right adjoint right inverse. Our task is thus to show that this right adjoint right inverse exists for $\text{Hom}_A(f, g)$ if and only if this right adjoint right inverse exists for $\text{Hom}_A(p_1, g)$. 

105
From the defining pullback (3.4.2) that constructs the comma ∞-category $\text{Hom}_A(p_1, g)$ reproduced below-left, we have the pullback square below-right:

\[
\begin{array}{ccc}
\text{Hom}_A(p_1, g) & \longrightarrow & \text{Hom}_A(A, g) \\
\downarrow & & \downarrow \\
C \times \text{Hom}_A(f, A) & \overset{C \times p_1}{\longrightarrow} & C \times A \\
\downarrow & & \downarrow \\
\text{Hom}_A(f, A) & \longrightarrow & A
\end{array}
\]

Thus, by Lemma 3.6.6, the composition-identity fibered adjunction of Example 3.6.11 pulls back along the functors $g \times f : C \times B \to A \times A$ to define a fibered adjunction

\[
\begin{array}{ccc}
\text{Hom}_A(p_1, g) & \cong & \text{Hom}_A(A, g) \times \text{Hom}_A(f, A) \\
\downarrow & & \downarrow \\
\text{Hom}_A(f, A) & \longrightarrow & \text{Hom}_A(f, g)
\end{array}
\]

which then composes with the projection $\pi : C \times B \to C$ to give a fibered adjunction over $C$

\[
\begin{array}{ccc}
\text{Hom}_A(p_1, g) & \cong & \text{Hom}_A(f, g) \\
\downarrow & & \downarrow \\
\text{Hom}_A(p_1, g) & \longrightarrow & \text{Hom}_A(f, g)
\end{array}
\]

between the codomain-projection for $\text{Hom}_A(p_1, g)$ and the codomain projection for $\text{Hom}_A(f, g)$, considered as objects of the sliced ∞-cosmos $\mathcal{K}/C$. Now by Corollary 3.6.9, $p_1 : \text{Hom}_A(f, g) \to C$ admits a right adjoint right inverse just when the object on the right admits a terminal element, again considered as an object of $\mathcal{K}/C$, while $p_1 : \text{Hom}_A(p_1, g) \to C$ similarly admits a right adjoint right inverse just when the object on the left admits a terminal element. By Theorem 2.4.2, a terminal element on either side is carried by the appropriate right adjoint to a terminal element on the other side. This proves the equivalence of these right lifting conditions conditions.

Now we assume that either and thus both absolute right liftings exist. Observe that the rightmost adjoint $(\text{id}_{\text{cod}(-)}, -) : \text{Hom}_A(f, g) \to \text{Hom}_A(p_1, g)$ is characterized up to fibered isomorphism by the
pasting equality:

\[
\begin{array}{c}
\text{Hom}_A(f, g) \\
p_1 \\
\downarrow \phi \\
\text{Hom}_A(p_1, g) \\
p_1 \\
\downarrow (\text{id}_{\text{cod}(\cdot)})_r \\
C \\
\downarrow s \\
A \\
p_1
\end{array}
= 
\begin{array}{c}
\text{Hom}_A(f, A) \\
p_1 \\
\downarrow \phi^* \\
\text{Hom}_A(p_1, g) \\
p_0 \\
\downarrow (\text{id}_{\text{cod}(\cdot)})_r \\
C \\
\downarrow s \\
A \\
p_1
\end{array}
\]

where \(\phi^* : \text{Hom}_A(f, g) \to \text{Hom}_A(f, A)\) is the functor that encodes the factorization of the comma cone for \(\text{Hom}_A(f, g)\) through the comma cone for \(\text{Hom}_A(f, A)\). By Theorem 3.5.12, the functor \(\rho^* : C \to \text{Hom}_A(f, g)\) defines a right adjoint right inverse to \(p_1 : \text{Hom}_A(f, g) \to C\). Thus by the argument just given the composite of \(\rho^*\) and \((\text{id}_{\text{cod}(\cdot)})_r\) defines a right adjoint right inverse to \(p_1 : \text{Hom}_A(p_1, g) \to C\), encoding the data of an absolute right lifting of \(g\) through \(p_1\), necessarily isomorphic to the pair \((i, \epsilon)\). From the pasting diagram

\[
\begin{array}{c}
\text{Hom}_A(f, A) \\
p_1 \\
\downarrow \phi^* \\
\text{Hom}_A(p_1, g) \\
p_0 \\
\downarrow (\text{id}_{\text{cod}(\cdot)})_r \\
C \\
\downarrow s \\
A \\
p_1
\end{array}
= 
\begin{array}{c}
\text{Hom}_A(f, A) \\
p_1 \\
\downarrow \phi^* \\
\text{Hom}_A(p_1, g) \\
p_0 \\
\downarrow (\text{id}_{\text{cod}(\cdot)})_r \\
C \\
\downarrow s \\
A \\
p_1
\end{array}
\]

we see that the absolute right lifting diagram so-encoded is given by

\[
\begin{array}{c}
\text{Hom}_A(f, A) \\
p_1 \\
\downarrow \phi^* \\
\text{Hom}_A(p_1, g) \\
p_0 \\
\downarrow (\text{id}_{\text{cod}(\cdot)})_r \\
C \\
\downarrow s \overset{\|}{\longrightarrow} A
\end{array}
\]

as claimed.

3.6.14. EXAMPLE. The left representation of a functor \(A^f : A^V \to A^U\) induced by cotensoring with a map of simplicial sets \(f : U \to V\) is itself definable as a cotensor with the simplicial set formed by
attaching $V$ to the domain end of the cylinder $U \times 2$ via the map $f$:

$$
\begin{array}{c}
\Hom_A(A^f, A) \cong A^{\text{cone}(f)} \\
\downarrow (p_1, p_0) \\
A^U \times A^V \\
\downarrow \text{id} \times A^f \\
A^U \times A^U
\end{array}
\xrightarrow{\phi^*} \xrightarrow{\gamma} \xrightarrow{\text{id} + \phi} 

\begin{array}{c}
U + U \\
\downarrow f + U \\
U \times 2 \\
\downarrow r \\
\text{cone}(f)
\end{array}
$$

Proposition 3.6.12 establishes a correspondence between absolute right lifting problems

in which a single functor $i: D \to A^{\text{cone}(f)}$ is used to encode the data of both the functor

$$
\begin{array}{c}
\rho := D \\
\downarrow d \\
A^U
\end{array}
\xrightarrow{r} 

\begin{array}{c}
A^V \\
\downarrow p_0 \\
A^{\text{cone}(f)}
\end{array}
\xrightarrow{\phi^*} 

\begin{array}{c}
\alpha := D \\
\downarrow i \\
A^{\text{cone}(f)}
\end{array}
\xrightarrow{\text{id} \times \phi} 

\begin{array}{c}
A^{\text{cone}(f)} \\
\downarrow p_1 \\
A^U
\end{array}
$$

Exercises.

3.6.i. EXERCISE. Let $B$ be an object in a 2-category and consider a map

$$
\begin{array}{c}
E \\
\downarrow f \\
B
\end{array}
\xrightarrow{\gamma} 

\begin{array}{c}
F \\
\downarrow \gamma
\end{array}
$$

between isofibrations over $B$. Prove that if $f$ is an equivalence in the ambient 2-category then $f$ is also an equivalence in the slice 2-category of isofibrations over $B$, 1-cells that form commutative triangles over $B$, and 2-cells that lie over $B$ in the sense that they whisker with the codomain isofibration to the identity 2-cell on the domain isofibration.

3.6.ii. EXERCISE. Under the correspondence of Corollary 3.5.11, show that the following are equivalent:

(i) $\alpha: f \Rightarrow g$ is an isomorphism.

(ii) The functor $\gamma^*: \Hom_B(B, f) \to \Hom_B(B, g)$ defines a fibered equivalence over $A \times B$.

(iii) The functor $\gamma^*: \Hom_B(g, B) \to \Hom_B(f, B)$ defines a fibered equivalence over $B \times A$.

3.6.iii. EXERCISE. Let $F: \mathcal{A} \to \mathcal{B}$ be a smoothing 2-functor. Use Lemma 2.1.11 to show how that any adjunction in $\mathcal{B}$ can be lifted to an adjunction in $\mathcal{A}$. Demonstrate furthermore that if we have previously specified a lift of the objects, 1-cells, and either the unit or counit of the adjunction in $\mathcal{B}$, then there is a lift of the remaining 2-cell that combines with the previously specified data to define an adjunction in $\mathcal{A}$. This proves a more precise version of Lemma 3.6.7.

3.6.iv. EXERCISE. Extend the proof of Proposition 3.6.12 to prove that a square

\begin{array}{c}
B \\
\downarrow f \\
A
\end{array}
\xrightarrow{b} 

\begin{array}{c}
B' \\
\downarrow f' \\
A'
\end{array}
\xrightarrow{a}
preserves the absolute right lifting below-left if and only if the induced square preserves the absolute right lifting below-right:

\[
\begin{array}{ccc}
B & \xrightarrow{b} & B' \\
\downarrow{r} & & \downarrow{f'} \\
C & \xrightarrow{g} & A \\
\end{array}
\quad\text{Hom}_A(f, A) \xrightarrow{\text{Hom}_A(b, g)} \text{Hom}_{A'}(f', A')
\]

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A \\
\downarrow{i} & & \downarrow{p_1} \\
\end{array}
\quad\text{Hom}_A(f, A) \xrightarrow{\text{Hom}_A(b, g)} \text{Hom}_{A'}(f', A')
\]
CHAPTER 4

Adjunctions, Limits, and Colimits II

In Chapter 2, we develop the basic theory of adjunctions between ∞-categories and limits and colimits of diagrams valued in ∞-categories by characterizing these notions in terms of absolute lifting diagrams in the the homotopy 2-category of ∞-categories, functors, and natural transformations in an ∞-cosmos. While absolute lifting diagrams are expedient for proving theorems relating adjunctions, limits, and colimits, they don't obviously express the familiar universal properties associated to these notions. In this chapter, we use the comma ∞-categories of Chapter 3 as a vehicle to give precise expressions to these universal properties, and prove that new characterizations of adjunctions, limits, and colimits in this language are equivalent to the definitions given previously. In fact, many of the main results in this section are mere special cases of the general theorems characterizing representable comma ∞-categories.

Using the theory developed in Chapter 3, in §4.1 we quickly prove a variety of results describing the universal property of adjunctions. In particular, Theorem 3.5.8 specializes in Proposition 4.1.1 to characterize adjoint pairs of functors \( f: B \to A \) and \( u: A \to B \) via a “transposing equivalence” \( \text{Hom}_A(f, A) \cong_{A \times B} \text{Hom}_B(B, u) \), while Theorem 3.5.12 specializes in Proposition 4.1.6 to give a criterion that guarantees that a left or right adjoint to a given functor exists.

In an interlude in §4.2, we introduce the ∞-categories of cones over or under a diagram as a comma ∞-category. When the indexing shape for the diagrams is given by a simplicial set, an equivalent model for these ∞-categories can be built from Joyal’s join construction. The ∞-categories of cones over or under a diagram feature prominently in the study of the universal properties of limits and colimits in §4.3. There we see that Theorem 3.5.8 specializes to prove Proposition 4.3.1, characterizing a limit of a diagram as a right representation for the ∞-category of cones of the diagram, while Theorem 3.5.12 specializes in Proposition 4.3.2 to characterize a limit cone as a terminal element in the ∞-category of cones.

Since the proofs of the main results in this chapter have appeared already in Chapter 3 where they are proven in a more general setting, we are able to focus our efforts here on applications. In §4.4 we introduce pointed ∞-categories, which have an element that is both initial and terminal, and show how this may be used to construct the loops \( \vdash \) suspension adjunction. Pointed ∞-categories that satisfy a few additional properties are called stable. While exploring the properties of stable ∞-categories, we discover a number of equivalent characterizations, enumerated in Theorem 4.4.12.

The fibered equivalences that characterize adjunctions, limits, and colimits can be understood as ∞-categorical analogues of Eilenberg and Mac Lane’s famous natural equivalences [41]. To express this “naturality,” we will explain how arrows in the base ∞-categories act covariantly-functorially on the fibers of the codomain-projection functor and contravariantly-functorially on the fibers of the domain-projection functor associated to a comma ∞-category. This is the subject of Chapter 5.

111
4.1. The Universal Property of Adjunctions

Our first result shows that an adjunction between an opposing pair of functors can equally be encoded by a “transposing equivalence” between their left and right representations as comma ∞-categories.

4.1.1. Proposition (adjunction as fibered equivalence). An opposing pair of functors \( u : A \to B \) and \( f : B \to A \) define an adjunction \( f \dashv u \) if and only if \( \text{Hom}_A(f, A) \cong_{A \times B} \text{Hom}_B(B, u) \).

This is a special case of Theorem 3.5.8, so no further argument is required, but we proffer a short proof nevertheless to review the results proven in §3.5.

Proof. If \( f \dashv u \), then Lemma 2.3.6 tells us that its counit \( \varepsilon : f u \Rightarrow \text{id}_A \) defines an absolute right lifting diagram. Theorem 3.5.8 then tells us that the 1-cell induced by the left-hand pasted composite

\[
\begin{array}{ccc}
\text{Hom}_B(B, u) & \xleftarrow{\phi} & \text{Hom}_A(f, A) \\
p_1 & \xleftarrow{\varepsilon} & p_0 \\
A & \xleftarrow{u} & B \\
\phi \downarrow & & \phi \downarrow \\
a & \xleftarrow{f} & a
\end{array}
\]

defines a fibered equivalence \( \text{Hom}_B(B, u) \cong_{A \times B} \text{Hom}_A(f, A) \). We interpret this result as saying that in the presence of an adjunction \( f \dashv u \), the right comma cone over \( u \) transposes to define the left comma cone over \( f \).

Conversely, Theorem 3.5.8 tells us that from a fibered equivalence \( \text{Hom}_B(B, u) \cong_{A \times B} \text{Hom}_A(f, A) \) one can extract a 2-cell that defines an absolute right lifting diagram

\[
\begin{array}{ccc}
& & B \\
& u \downarrow & \downarrow f \\
A & \xleftarrow{\varepsilon} & A
\end{array}
\]

Lemma 2.3.6 then tells us that this 2-cell defines the counit of an adjunction \( f \dashv u \). \( \Box \)

4.1.2. Observation (the transposing equivalence). To justify referring to the induced functor

\( \varepsilon \cdot f(\cdot) : \text{Hom}_B(B, u) \Rightarrow \text{Hom}_A(f, A) \)

\footnote{If desired, an inverse equivalence can be constructed by applying the dual of Theorem 3.5.8 to the absolute left lifting diagram presented by the unit.}
as a transposing equivalence, recall that the transpose of a 2-cell \( \chi : b \Rightarrow ua \) across the adjunction \( f \dashv u \) is computed by the left-hand pasting diagram below:

\[
\begin{array}{c}
\xymatrix{
A \ar[r]^{f} \ar[d]_{u} & B \ar[d]^{b} \\
A \ar[r]_{a} & B \ar[d]_{\xi} \\
& \text{Hom}_B(B, u) \\
& \text{Hom}_A(f, A) \\
& A \ar[ul]^{p_0} \ar[ur]_{\phi} \\
& & A \ar[ul]^{p_1} \ar[ur]_{\xi} \\
& & B \ar[ul]^{f} \ar[ur]_{u} \\
& & X \ar[ul]^{\chi} \ar[ur]_{\text{Hom}_B(B, u)} \\
& & X \ar[ul]^{a} \ar[ur]_{b} \\
& A \ar[l]_{\xi} \\
& X \ar[l]^{\text{Hom}_B(B, u)} \ar[u]_{\chi} \\
& X \ar[l]^{X} \end{array}
\]

By the weak universal property of the right comma cone over \( u \), the 2-cell \( \chi \) is represented by the induced functor \( "\chi" : X \to \text{Hom}_B(B, u) \), which then composes with the transposing equivalence to define a functor \( \langle \epsilon \cdot f(\chi) \rangle : X \to \text{Hom}_A(f, A) \) that represents the transpose of \( \chi \), by the pasting diagram equalities from right to left. This observation also justifies our notation, in which we name the fibered equivalence \( \langle \epsilon \cdot f(\cdot) \rangle "\chi" \) after the formula for adjoint transposition.

4.1.3. COROLLARY. An opposing pair of functors \( u : A \to B \) and \( f : B \to A \) define an adjunction \( f \dashv u \) if and only if there is an equivalence \( \text{Hom}_A(f, a) \simeq_{\times Y} \text{Hom}_B(b, ua) \) for any pair of generalized elements \( a : X \to A \) and \( b : Y \to B \).

**Proof.** When \( f \dashv u \) in the \( \infty \)-cosmos \( \mathcal{K} \), pullback along \( a \times b : X \times Y \to A \times B \) defines a cosmological functor \( (a \times b)^* : \mathcal{K}_{/A \times B} \to \mathcal{K}_{/X \times Y} \) that carries the equivalence \( \text{Hom}_A(f, A) \simeq_{A \times B} \text{Hom}_B(B, u) \) of Proposition 4.1.1 to an equivalence \( \text{Hom}_A(f, a) \simeq_{X \times Y} \text{Hom}_B(b, ua) \). The converse implication is given by the case where the generalized elements are the identity functors \( \text{id}_A \) and \( \text{id}_B \) and Proposition 4.1.1. □

4.1.4. REMARK. In particular, the equivalence of Proposition 4.1.1 pulls back to define an equivalence of internal mapping spaces, introduced in 3.4.9. In Corollary 12.2.15, we will see that in an \( \infty \)-cosmos of \((\infty,1)\)-categories a natural transformation \( \epsilon : fu \Rightarrow \text{id}_A \) defines the counit of an adjunction if and only if the map \( \langle \epsilon \cdot f(\cdot) \rangle : \text{Hom}_B(b, u) \to \text{Hom}_A(f, A) \) defines equivalences of internal mapping spaces \( \text{Hom}_B(b, ua) \simeq \text{Hom}_A(fb, a) \) for any pair of elements \( a : 1 \to A \) and \( b : 1 \to B \).

Comma \( \infty \)-categories also provide a vehicle for expressing the universal properties of unit and counit transformations.

4.1.5. PROPOSITION (the universal property of units and counits). Consider an adjunction

\[
\begin{array}{c}
B \ar[r]^{f} \ar[d]_{u} & A \\
& 1 \ar[u]^{\text{id}_B} \end{array}
\]

with unit \( \eta : \text{id}_B \Rightarrow uf \) and counit \( \epsilon : fu \Rightarrow \text{id}_A \).

Then for each element \( a : 1 \to A \), the component \( \epsilon_a \) defines a terminal element of \( \text{Hom}_A(f, a) \), and for each element \( b : 1 \to B \), the component \( \eta_b \) defines an initial element of \( \text{Hom}_B(b, u) \).

**Proof.** By Corollary 4.1.3, the fibered equivalence \( \text{Hom}_A(f, A) \simeq_{A \times B} \text{Hom}_B(B, u) \) of Proposition 4.1.1 pulls back to define equivalences

\[
\text{Hom}_A(f, a) \simeq_{B} \text{Hom}_B(B, ua) \quad \text{and} \quad \text{Hom}_A(fb, A) \simeq_{A} \text{Hom}_B(b, u).
\]
By Corollary 3.5.10, $\text{id}_{ua}$ induces a terminal element in $\text{Hom}_B(B, ua)$ and by Lemma 2.2.7 its image across the equivalence $\text{Hom}_B(B, ua) \xrightarrow{\sim} \text{Hom}_A(f, a)$ is again a terminal element. By Observation 4.1.2 this element represents the transposed 2-cell: the component of the counit $\varepsilon$ at the element $a$. The proof that the unit component $\eta_f$ defines an initial element of $\text{Hom}_B(b, u)$ is dual. □

The universal property of unit and counit components captured in Proposition 4.1.5 gives the main idea behind the adjoint functor theorems: a functor $f : B \to A$ admits a right adjoint just when for each element $a : 1 \to A$, the $\infty$-category $\text{Hom}_A(f, a)$ admits a terminal element. The image of this terminal element under the domain-projection functor $p_0 : \text{Hom}_A(f, a) \to B$ then defines the element $ua : 1 \to B$ and the comma cone defines the component of the counit at $a$. The universal property of these unit components is then used to extend the mapping on elements to a functor $u : A \to B$.

The result just stated is true in the $\infty$-cosmos of quasi-categories and in other $\infty$-cosmoi where universal properties are generated by the terminal $\infty$-category $1$; see Corollary 12.2.7. What is true in all $\infty$-cosmoi is the version of the result just stated where the quantifier “for each element $a : 1 \to A$” is replaced with “for each generalized element $a : X \to A$,” in which case the meaning of “terminal element” should be enhanced to “terminal element over $X$”; see the remark after Corollary 3.5.10. Since every generalized element factors through the universal generalized element, namely the identity functor at $A$, it suffices to prove:

4.1.6. PROPOSITION. A functor $f : B \to A$ admits a right adjoint if and only if $\text{Hom}_A(f, A)$ admits a terminal element over $A$. Dually, $f : B \to A$ admits a left adjoint if and only if $\text{Hom}_A(A, f)$ admits an initial element over $A$.

PROOF. By Proposition 4.1.1, $f : B \to A$ admits a right adjoint if and only if the comma $\infty$-category $\text{Hom}_A(f, A)$ is right representable. Theorem 3.5.12 specializes to tell us that this is the case if and only if the codomain-projection functor $p_1 : \text{Hom}_A(f, A) \to A$ admits a right adjoint right inverse, which by Corollary 3.6.9 is equivalent to postulating a terminal element over $A$. □

The same suite of results from §3.5 specialize to theorems that encode the universal properties of limits and colimits. Before proving these, we first construct the $\infty$-category of cones over a fixed diagram and also construct alternate models for the $\infty$-categories of cones over varying $J$-indexed diagrams, in the case where $J$ is a simplicial set.

Exercises.

4.1.i. EXERCISE (4.3.13). Specialize Proposition 4.1.1 to the case of adjunctions

$$
\begin{array}{ccc}
1 & \xrightarrow{f} & A \\
\downarrow & & \downarrow \\
1 & \xleftarrow{f} & A 
\end{array}
$$

to discover an alternate characterization of initial and terminal elements.

---

Footnote: Recall from Example 2.3.9 that a terminal element is a colimit of the identity functor. The technical conditions in Freyd’s General Adjoint Functor Theorem and Special Adjoint Functor Theorem are deployed to reduce this large colimit to a small colimit and guarantee its existence; see [99, §4.6] for a 1-categorical exposition of these results. Analogous theorems have recently been proven in the ($\infty, 1$)-categorical context by Nguyen, Raptis, and Schrade [54].
4.1.ii. Exercise. Fix a parallel pair of fully specified adjunctions

\[ B \xleftarrow{f} A \xrightarrow{u} B' \xrightarrow{f'} A' \]

with unit \( \eta \colon \text{id}_B \Rightarrow uf \) and counit \( \varepsilon \colon fu \Rightarrow \text{id}_A \), and

\[ B \xleftarrow{f'} A \xrightarrow{u'} B' \xrightarrow{f} A' \]

with unit \( \eta' \colon \text{id}_B \Rightarrow u'f' \) and counit \( \varepsilon' \colon f'u' \Rightarrow \text{id}_A \).

Then there is a bijection between natural transformations \( \alpha \colon f' \Rightarrow f \) and \( \beta \colon u \Rightarrow u' \) as a special case of the mates correspondence of Definition B.3.3. Prove that the transposing equivalence of Proposition 4.1.1 is natural with respect to pre-composing with a 2-cell \( \alpha \colon f' \Rightarrow f \) or post-composing with its mate \( \beta \colon u \Rightarrow u' \) by using Corollary 3.5.11 to conclude that there is a fibered natural isomorphism between the functors

\[
\begin{align*}
\text{Hom}_A(f, A) & \xrightarrow{\alpha \cdot \text{id}} \text{Hom}_A(f', A) \\
\text{Hom}_B(B, u) & \xrightarrow{\beta \cdot \text{id}} \text{Hom}_B(B, u')
\end{align*}
\]

over \( A \times B \).

4.2. \( \infty \)-Categories of Cones

The comma \( \infty \)-category construction can be used to define the \( \infty \)-category of cones over or under a given diagram. Since these \( \infty \)-categories feature in a key way in the description of the universal properties of limits and colimits, we take time in this section to explore a few equivalent models for this construction.

A cone over a diagram \( d \colon 1 \to A \) with summit \( a \colon 1 \to A \) is a natural transformation \( \Delta a \Rightarrow d \), where \( \Delta \colon A \to A \) is the constant diagram functor of Definition 2.3.1. This motivates the following definition.

4.2.1. Definition (the \( \infty \)-category of cones). Let \( d \colon 1 \to A \) be a \( J \)-shaped diagram in an \( \infty \)-category \( A \). The \( \infty \)-category of cones over \( d \) is the comma \( \infty \)-category \( \text{Hom}_A(\Delta, d) \) from the constant diagram functor \( \Delta \) to \( d \). Dually, the \( \infty \)-category of cones under \( d \) is the comma \( \infty \)-category \( \text{Hom}_A(d, \Delta) \).

By replacing the diagram leg of the cospans, Definition 4.2.1 can be modified to allow \( d \colon D \to A \) to be a family of diagrams. In the universal case, when \( d \) is the identity functor \( \text{id}_A \colon A \to A \), this defines the \( \infty \)-category \( \text{Hom}_A(\Delta, A) \) of cones over or under any diagram of shape \( J \).

In the case where the indexing shape \( J \) is a simplicial set (as opposed to an \( \infty \)-category in a cartesian closed \( \infty \)-cosmos), there is another model of the \( \infty \)-categories of cones over or under a diagram that
may be constructed using the simplicial join construction first developed by Ehlers and Porter [39]. The equivalence of models is a consequence of the equivalence between the join operation and the so-called “fat join” introduced by Joyal [61, §9]. As Lemma 4.2.3 reveals, a particular instance of the fat join construction gives the shape of the cones appearing in Definition 4.2.1. We now introduce these notions.

4.2.2. DEFINITION (fat join). The fat join of simplicial sets $I$ and $J$ is the simplicial set constructed by the following pushout:

$$
\begin{array}{c}
(I \times J) \amalg (I \times J) \\
\downarrow \quad \downarrow \\
I \times 2 \times J \\
\end{array} \rightarrow 
\begin{array}{c}
I \amalg J \\
\downarrow \\
\mathbb{I} + \mathbb{I} \\
\end{array}
$$

from which it follows that

$$(I \amalg J)_n := I_n \amalg (\coprod_{[n] \to [1]} I_n \times J_n) \amalg J_n.$$  

Note there is a natural map $I \amalg J \rightarrow \mathbb{2}$ induced by the projection $\pi: I \times 2 \times J \rightarrow \mathbb{2}$ so that $I$ is the fiber over 0 and $J$ is the fiber over 1:

$$
\begin{array}{c}
I \amalg J \\
\downarrow \\
\mathbb{1} + \mathbb{1} \\
\end{array} \rightarrow 
\begin{array}{c}
I \amalg J \\
\downarrow \\
\mathbb{2} \\
\end{array}
$$

The $\infty$-categories of cones over or under any $J$-shaped diagram can be re-described as follows:

4.2.3. LEMMA. For any simplicial set $J$ and $\infty$-category $A$ we have natural isomorphisms

$$\text{Hom}_A(\Delta, A^J) \cong A^3 \quad \text{and} \quad \text{Hom}_A(A^J, \Delta) \cong A^3.$$  

PROOF. The simplicial cotensor $A((-)): s\text{Set}^{op} \rightarrow \mathcal{K}$ carries the pushout of Definition 4.2.2 to the pullback squares that define the left and right representations of $\Delta: A \rightarrow A^J$ as a comma $\infty$-category:

$$
\begin{array}{c}
A^3 \\
\downarrow \\
A^J \times A \\
\downarrow \times \Delta \\
A \times A
\end{array} \quad \text{and} \quad 
\begin{array}{c}
A^3 \\
\downarrow \\
A \times A \\
\downarrow \Delta \times \text{id} \\
A \times A
\end{array}
$$

4.2.4. DEFINITION (join). The join of simplicial sets $I$ and $J$ is the simplicial set $I \star J$

$$
\begin{array}{c}
I \amalg J \\
\downarrow \\
\mathbb{1} + \mathbb{1} \\
\end{array} \rightarrow 
\begin{array}{c}
I \amalg J \\
\downarrow \\
\mathbb{2} \\
\end{array}
$$

with

$$(I \star J)_n := I_n \amalg (\coprod_{0 \leq k < n} I_{n-k-1} \times J_k) \amalg J_n$$

and with the vertices of these $n$-simplices oriented so that there is a canonical map $I \star J \rightarrow \mathbb{2}$ so that $I$ is the fiber over 0 and $J$ is the fiber over 1. See Definitions D.2.2 or the original sources [39] and [59, §3] for more details.
The join functor $- \star J: sSet \to sSet$ preserves connected colimits but not the initial object or other coproducts, but this can be rectified by replacing the codomain by the slice category under $J$: the functor $- \star J: sSet \to \mathcal{I}/sSet$ preserves all colimits, as proven in Lemma D.2.7. Contextualized in this way, the join admits a right adjoint, defined by Joyal’s slice construction, which carries a simplicial map $f: J \to X$ to a simplicial set traditionally denoted by $X_{/f}$.

4.2.5. PROPOSITION (join $\dashv$ slice adjunction). The join functors admit right adjoints $sSet \xleftarrow{\perp} \mathcal{I}/sSet$ and $sSet \xleftarrow{\perp} \mathcal{I}/sSet$ defined by the natural bijections

\[
\left\{ \Delta[n] \to hX \right\} := \left\{ I \star \Delta[n] \xrightarrow{h} X \right\} \quad \text{and} \quad \left\{ \Delta[n] \to X_{/k} \right\} := \left\{ \Delta[n] \star J \xrightarrow{J} X \right\}.
\]

Proof. As in the statement, the simplicial set $X_{/k}$ is defined to have $n$-simplices corresponding to maps $\Delta[n] \star J \to X$ under $J$, with the right action by the simplicial operators $[m] \to [n]$ given by pre-composition with $\Delta[m] \to \Delta[n]$. Since the join functor $- \star J: sSet \to \mathcal{I}/sSet$ preserves colimits, this extends to a bijection between maps $I \to X_{/k}$ and maps $I \star J \to X$ under $J$ that is natural in $I$ and in $k: J \to X$. □

4.2.6. NOTATION. For any simplicial set $J$, we write

\[ J^\triangleleft := \mathbb{1} \star J \quad \text{and} \quad J^\triangleright := J \star \mathbb{1} \]

and write $\perp$ for the cone vertex of $J^\triangleleft$ and $\top$ for the cone vertex of $J^\triangleright$ contributed by the terminal simplicial set $\mathbb{1}$. These simplicial sets are equipped with canonical inclusions

\[ J^\triangleleft \hookrightarrow J \hookrightarrow J^\triangleright \]

4.2.7. PROPOSITION (join vs fat join). For any simplicial sets $I$ and $J$ and any $\infty$-category $A$, there is a natural equivalence

\[
A^{I \star J} \xrightarrow{\sim} A^{I \triangleright J}.
\]

Proof. There is a canonical map of simplicial sets

\[
(I \times J) \amalg (I \times J) \xrightarrow{\pi_I \amalg \pi_J} I \amalg J
\]

\[
I \times 2 \times J \xrightarrow{r} I \circ J \xrightarrow{\star} I \star J
\]
that commutes with the inclusions of the fibers \( I \amalg J \) over the endpoints of \( 2 \). An \( n \)-simplex in \( I \circ J \) that does not lie in either fiber is given by the data of a triple \( (\alpha: [n] \to [1], \sigma \in I_n, \tau \in J_n) \). The dashed map carries this simplex to the pair \( (\sigma|_{\{0, \ldots, k\}} \in I_k, \tau|_{\{k+1, \ldots, n\}} \in J_{n-k-1}) \) representing an \( n \)-simplex of \( I \star J \), where \( k \in [n] \) is the maximal vertex in \( \alpha^{-1}(0) \). Proposition D.6.4, or Lurie’s [74, 4.2.1.2], prove that this map induces a natural equivalence \( Q^I \star J \simeq Q^I \times Q^J \) of quasi-categories over \( Q^J \times Q^I \). Taking \( Q \) to be the functor space \( \text{Fun}(X, A) \) proves the claimed equivalence for general \( \infty \)-categories.

These results combine to provide an alternate model for the \( \infty \)-categories of cones over or under a diagram.

4.2.8. COROLLARY. There are comma squares

\[
\begin{array}{ccc}
A^\land & \xrightarrow{\phi} & A \\
\downarrow \text{res} & & \downarrow \Delta \\
A & \xrightarrow{\Delta} & A \\
\end{array}
\quad
\begin{array}{ccc}
A^\lor & \xleftarrow{\phi} & A \\
\uparrow \text{ev}_\perp & & \uparrow \text{ev}_\perp \\
A & \xleftarrow{\Delta} & A \\
\end{array}
\quad
\begin{array}{ccc}
J \amalg J & \xrightarrow{J \amalg J} & I \amalg J \\
\downarrow \circ & & \downarrow \circ \\
J \times 2 & \xrightarrow{J \times 2} & I \circ J \\
\downarrow 2 & & \downarrow 2 \\
J \amalg J & \xrightarrow{J \amalg J} & I \circ J \\
\end{array}
\quad
\begin{array}{ccc}
J \amalg J & \xleftarrow{J \amalg J} & I \amalg J \\
\uparrow \circ & & \uparrow \circ \\
J \times 2 & \xleftarrow{J \times 2} & I \circ J \\
\downarrow 2 & & \downarrow 2 \\
J \amalg J & \xleftarrow{J \amalg J} & I \circ J \\
\end{array}
\quad
\begin{array}{ccc}
A^\land & \xrightarrow{p_0} & (A^I)^2 \\
\downarrow \text{res} & & \downarrow \Delta \text{ev}_\perp \\
A^I & \xrightarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
A^\lor & \xleftarrow{p_0} & (A^I)^2 \\
\uparrow \text{res} & & \uparrow \Delta \text{ev}_\perp \\
A^I & \xleftarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
\Delta \text{ev}_\perp & & \Delta \text{ev}_\perp \\
\downarrow & & \downarrow \\
A^\land & \xrightarrow{p_0} & (A^I)^2 \\
\downarrow \text{res} & & \downarrow \Delta \text{ev}_\perp \\
A^I & \xrightarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
\Delta \text{ev}_\perp & & \Delta \text{ev}_\perp \\
\uparrow & & \uparrow \\
A^\lor & \xleftarrow{p_0} & (A^I)^2 \\
\uparrow \text{res} & & \uparrow \Delta \text{ev}_\perp \\
A^I & \xleftarrow{p_1} & A^I \\
\end{array}
\]

which pullback over a diagram \( d: D \to A^I \) to define alternate models for the \( \infty \)-categories of cones over or under \( d \).

PROOF. Proposition 4.2.7 constructs fibered equivalences \( A^\land \simeq A^\land \times A^I \) and \( A^\lor \simeq A \times A^I \). By Lemma 4.2.3, \( A^\land \) and \( A^\lor \) are comma \( \infty \)-categories. Thus, Proposition 3.4.11 implies that the fibered equivalences equip \( A^\land \) and \( A^\lor \) with comma cone squares. The 2-cells in (4.2.9) are represented by the horizontal composite maps

\[
\begin{array}{ccc}
J \amalg J & \xrightarrow{J \amalg J} & I \amalg J \\
\downarrow \circ & & \downarrow \circ \\
J \times 2 & \xrightarrow{J \times 2} & I \circ J \\
\downarrow 2 & & \downarrow 2 \\
J \amalg J & \xrightarrow{J \amalg J} & I \circ J \\
\end{array}
\quad
\begin{array}{ccc}
J \amalg J & \xleftarrow{J \amalg J} & I \amalg J \\
\uparrow \circ & & \uparrow \circ \\
J \times 2 & \xleftarrow{J \times 2} & I \circ J \\
\downarrow 2 & & \downarrow 2 \\
J \amalg J & \xleftarrow{J \amalg J} & I \circ J \\
\end{array}
\quad
\begin{array}{ccc}
A^\land & \xrightarrow{p_0} & (A^I)^2 \\
\downarrow \text{res} & & \downarrow \Delta \text{ev}_\perp \\
A^I & \xrightarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
A^\lor & \xleftarrow{p_0} & (A^I)^2 \\
\uparrow \text{res} & & \uparrow \Delta \text{ev}_\perp \\
A^I & \xleftarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
\Delta \text{ev}_\perp & & \Delta \text{ev}_\perp \\
\downarrow & & \downarrow \\
A^\land & \xrightarrow{p_0} & (A^I)^2 \\
\downarrow \text{res} & & \downarrow \Delta \text{ev}_\perp \\
A^I & \xrightarrow{p_1} & A^I \\
\end{array}
\quad
\begin{array}{ccc}
\Delta \text{ev}_\perp & & \Delta \text{ev}_\perp \\
\uparrow & & \uparrow \\
A^\lor & \xleftarrow{p_0} & (A^I)^2 \\
\uparrow \text{res} & & \uparrow \Delta \text{ev}_\perp \\
A^I & \xleftarrow{p_1} & A^I \\
\end{array}
\]

which yield 2-cells

\[
\Delta \text{ev}_\perp
\]

upon cotensoring into \( A \).

4.2.10. WARNING (slices are not strict fibers). By Lemma 4.2.3, the fibers of \( A^\land \to A^I \) and \( A^\lor \to A^I \) over a diagram \( d: 1 \to A^I \) are isomorphic to the \( \infty \)-categories of cones \( \text{Hom}_{A^I}(\Delta, d) \) and \( \text{Hom}_{A^I}(d, \Delta) \).
In the \(\infty\)-cosmos of quasi-categories, it is tempting to believe that the fibers of the equivalent isofibrations \(A^r \to A^l\) and \(A^l \to A^l\) over \(d\) recover Joyal’s slice quasi-categories \(A_{/d}\) and \(d/A\), but from a direct comparison of the defining universal properties left as Exercise 4.2.ii, this can easily be seen not to be the case. However, Proposition D.6.5 proves that in the \(\infty\)-cosmos of quasi-categories that \(A_{/d} \simeq A \text{Hom}_{A^l}(\Delta, d)\) and \(d/A \simeq A \text{Hom}_{A^l}(d, \Delta)\) and thus the fiber of \(A^r \to A^l\) over \(d\) is equivalent to \(A_{/d}\) and the fiber of \(A^l \to A^l\) is equivalent to \(d/A\).

**Exercises.**

4.2.i. **Exercise.** Compute \(\Delta[n] \star \Delta[m]\) and \(\Delta[n] \odot \Delta[m]\) and define a section
\[
\Delta[n] \star \Delta[m] \to \Delta[n] \odot \Delta[m]
\]
to the map constructed in the proof of Proposition 4.2.7.

4.2.ii. **Exercise.** Compute the fiber of \(A^l \to A^l\) over \(d: 1 \to A^l\) in the \(\infty\)-cosmos of quasi-categories and prove that this quasi-category is not isomorphic to \(A_{/d}\).

4.2.iii. **Exercise** (\(61, 3.5\)). Simplicial sets, as a category of presheaves, is **locally cartesian closed**, meaning that the pullback functor
\[
s\text{Set}_{/V} \xrightarrow{f^*} n\text{Set}_{/U}
\]
associated to any map \(f: U \to V\) has a right adjoint \(\Pi_f\) called the **dependent product**. Show that the join \(I \star J\) can be defined as an object of \(n\text{Set}_{/2}\) as the dependent product of \(!+! : I + J \to 1 + 1\) along \(1 + 1 \hookrightarrow 2\).

4.3. **The Universal Property of Limits and Colimits**

To describe the universal properties of limits and colimits we return to the general context of Definition 2.3.1, simultaneously considering diagrams valued in an \(\infty\)-category that are indexed either by a simplicial set or by another \(\infty\)-category, in the case where the ambient \(\infty\)-cosmos is cartesian closed. As was the case for Proposition 4.1.1, Theorem 3.5.8 specializes immediately to the setting of Definition 2.3.7 to prove:

4.3.1. **Proposition** (co/limits represent cones). A family of diagrams \(d: D \to A^l\) admits a limit if and only if the \(\infty\)-category of cones \(\text{Hom}_{A^l}(\Delta, d)\) over \(d\) is right representable
\[
\text{Hom}_{A^l}(\Delta, d) \simeq_{D \times A} \text{Hom}_A(A, \ell),
\]
in which case the representing functor \(\ell: D \to A\) defines the limit functor. Dually, a family of diagrams \(d: D \to A^l\) admits a colimit if and only if the \(\infty\)-category of cones \(\text{Hom}_{A^l}(d, \Delta)\) under \(d\) is left representable
\[
\text{Hom}_{A^l}(d, \Delta) \simeq_{A \times D} \text{Hom}_A(c, A),
\]
in which case the representing functor \(c: D \to A\) defines the colimit functor. \(\square\)

Theorem 3.5.12 now specializes to tell us that such representations can be encoded by terminal or initial elements, a result which is easiest to interpret in the case of a single diagram rather than a family of diagrams.
4.3.2. **Proposition** (limits as terminal elements). A diagram \( d : 1 \to A^I \) of shape \( I \) in an \( \infty \)-category \( A \)

(i) admits a limit if and only if the \( \infty \)-category \( \text{Hom}_{A^I}(\Delta, d) \) of cones over \( d \) admits a terminal element, in which case the terminal element defines a limit cone, and

(ii) admits a colimit if and only if the \( \infty \)-category \( \text{Hom}_{A^I}(d, \Delta) \) of cones under \( d \) admits an initial element, in which case the initial element defines the colimit cone.

**Proof.** In the terminology of Definition 2.3.7, the limit cone refers to the 2-cell component of an absolute right lifting diagram:

\[
\begin{array}{ccc}
A & \xrightarrow{\ell} & A^I \\
\downarrow_{\epsilon} & & \downarrow_{\Delta} \\
1 & \xrightarrow{d} & A^I
\end{array}
\]

By Theorem 3.5.3, such an absolute right lifting diagram induces an equivalence \( \text{Hom}_A(A, \ell) \cong \text{Hom}_{A^I}(\Delta, d) \) over \( A \). By Corollary 3.5.10, the identity at \( \ell \) induces a terminal element of \( \text{Hom}_A(A, \ell) \) which the equivalence carries to a terminal element of the \( \infty \)-category of cones, this being the element \( \epsilon^\circ : 1 \to \text{Hom}_{A^I}(\Delta, d) \) that represents the limit cone \( \epsilon : \Delta \ell \Rightarrow d \).

Conversely, if \( \text{Hom}_{A^I}(\Delta, d) \) admits a terminal element, it defines a right adjoint right inverse to the codomain-projection functor \( p_1 : \text{Hom}_{A^I}(\Delta, d) \to 1 \). Theorem 3.5.12 then tells us that the natural transformation represented by this element defines an absolute right lifting of \( d \) through \( \Delta \). \( \Box \)

The uniqueness of limit and colimit cones up to isomorphism now follows by combining this result with Lemma 2.2.3. This can also be proven from the absolute lifting diagram characterization; see Exercise 2.3.vi.

4.3.3. **Remark.** The proof of Proposition 4.3.2 extends without change to the case of a family of diagrams \( d : D \to A^I \) indexed by a simplicial set \( J \) since Theorem 3.5.12 applies at this level of generality. For a family of diagrams \( d \) parametrized by \( D \) in an \( \infty \)-cosmos \( \mathcal{K} \), the \( \infty \)-category of cones defines an object \( p_1 : \text{Hom}_{A^I}(\Delta, A^I) \to D \) of the sliced \( \infty \)-cosmos \( \mathcal{K}_D \) and the initial and terminal elements referred to in the statement of Proposition 4.3.2 should be interpreted in \( \mathcal{K}_D \), as done in the statement of Corollary 3.6.9.

For aesthetic reasons, we state the following two results for diagrams indexed by simplicial sets so that we may deploy more elegant notation that may be easier to interpret. As Exercise 4.3.ii reveals, there is no mathematical reason to restrict to this special case. Indeed, the proof in fact uses the codomain-projection functor \( p_1 : \text{Hom}_{A^I}(\Delta, A^I) \to A^I \) in place of the equivalent isofibration \( \text{res} : A^I \to A^I \), and thus the plainer argument applies equally in the case of diagrams indexed by \( \infty \)-categories \( J \) in cartesian closed \( \infty \)-cosmoi that may or may not have a join operation available for indexing shapes.

4.3.4. **Proposition.** An \( \infty \)-category \( A \) admits a limit of a family of diagrams \( d : D \to A^I \) indexed by a simplicial set \( J \) if and only if there exists an absolute right lifting of \( d \) through the restriction functor

\[
\begin{array}{ccc}
A^{I\times} & \xrightarrow{\text{ran}} & A^I \\
\downarrow_{\text{res}} & & \downarrow_{\text{res}} \\
D & \xrightarrow{d} & A^I
\end{array}
\]

When these equivalent conditions hold, \( \epsilon \) is necessarily an isomorphism and may be chosen to be the identity.
Proof. By Definition 2.3.7, a family of diagrams \( d \) admits a limit if and only if it admits an absolute right lifting through \( \Delta: A \to A' \). By Proposition 3.6.12, such an absolute lifting diagram exists if and only if \( d \) admits an absolute right lifting through codomain-projection functor \( p_1: \text{Hom}_A(\Delta, A') \to A' \), in which case the 2-cell of this latter absolute right lifting diagram is invertible. By Corollary 4.2.8, the restriction functor \( \text{res}: A'^e \to A' \) is equivalent to this codomain-projection functor, so Exercise 3.5.ii implies that absolute right liftings of \( d \) through \( p_1 \) are equivalent to absolute right liftings of \( d \) through \( \text{res} \). If this absolute lifting diagram is inhabited by an invertible 2-cell, the isomorphism lifting property of the isofibration proven in Proposition 1.4.10 can be used to replace the functor \( \text{ran}: D \to A'^e \) with an isomorphic functor making the triangle commute strictly. □

Recall from Lemma 2.3.6 that absolute lifting diagrams can be used to encode the existence of adjoint functors. Combining this with Definition 2.3.2, Proposition 4.3.4 specializes to prove:

4.3.5. Corollary. An ∞-category \( A \) admits all limits indexed by a simplicial set \( J \) if and only if the restriction functor

\[
\begin{array}{ccc}
A'^e & \xleftarrow{\text{res}} & A' \\
\downarrow & & \downarrow \\
A & \xrightarrow{\text{ran}} & A
\end{array}
\]

admits a right adjoint, and admits all colimits indexed by a simplicial set \( J \) if and only if the restriction functor

\[
\begin{array}{ccc}
A'^e & \xleftarrow{\text{res}} & A' \\
\downarrow & & \downarrow \\
A & \xrightarrow{\text{lan}} & A
\end{array}
\]

admits a left adjoint. □

4.3.6. Remark. Since the restriction functor is an isofibration, Lemma 3.6.8 applies and the adjunctions of Corollary 4.3.5 can be defined so as to be fibered over the ∞-category of diagrams \( A' \).

We now apply the general theory we have developed to particular indexing shapes.

4.3.7. Definition (tensors and cotensors). Let \( K \) be a simplicial set and let \( a: 1 \to A \) be an element of an ∞-category \( A \). The \textit{tensor} \( K \otimes a \) of \( a \) by \( K \) is the colimit of the constant \( K \)-indexed diagram valued at \( a \), while the \textit{cotensor} \( a^K \) of \( a \) by \( K \) is the limit of the same diagram. Thus, the tensor and cotensor functors can be defined by the absolute lifting diagrams:

\[
\begin{array}{ccc}
A & \xrightarrow{K \otimes a} & A^K \\
\downarrow & & \downarrow \\
A & \xrightarrow{\Delta} & A^K
\end{array}
\]

\[
\begin{array}{ccc}
A & \xleftarrow{(-)^K} & A \\
\downarrow & & \downarrow \\
A & \xleftarrow{\Delta} & A^K
\end{array}
\]

By Theorem 3.5.3, these absolute lifting diagrams define fibered equivalences

\[
\text{Hom}_A(K \otimes -, A) \approx_{A \times A} \text{Hom}_A(\Delta, \Delta) \approx_{A \times A} \text{Hom}_A(A, (-)^K)
\]

which compose to define the fibered equivalence associated to an adjunction

\[
\begin{array}{ccc}
A & \xleftarrow{K \otimes -} & A \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
A & \xleftarrow{(-)^K} & A
\end{array}
\]

121
between the tensor and cotensor functors. By Corollary 4.1.3, the fibered equivalences that encode the universal properties of tensors and cotensors pullback over elements $a, x : 1 \to A$ to define equivalences of internal mapping spaces:

$$\text{Hom}_A(K \otimes a, x) \cong \text{Hom}_{Ak}(\Delta a, \Delta x) \cong \text{Hom}_A(a, x)^K \quad \text{and} \quad \text{Hom}_A(x, a^K) \cong \text{Hom}_{Ak}(\Delta x, \Delta a) \cong \text{Hom}_A(x, a)^K.$$  

4.3.8. Definition (span and cospan). A span in an $\infty$-category $A$ is a diagram indexed by the simplicial set

$$r := \Lambda^0[2]$$

formed by gluing two 1-simplices along their domain vertices. Dually, a cospan in $A$ is a diagram indexed by the simplicial set

$$\omega := \Lambda^2[2]$$

formed by gluing two 1-simplices along their codomain vertices. Cospans and spans in an $\infty$-category $A$ may be defined by gluing together a pair of arrows along their common codomains or domains respectively:

4.3.9. Definition (pushout and pullback). A pushout in an $\infty$-category $A$ is a colimit indexed by the simplicial set $r$, while a pullback in an $\infty$-category $A$ is a limit indexed by the simplicial set $\omega$. Cones over diagrams of shape $\omega$ or cones under diagrams of shape $r$ define commutative squares, diagrams of shape

$$\Box := r \triangleright \omega \cong 2 \times 2 \cong \omega \triangleleft r.$$  

A pullback square in an $\infty$-category $A$ is an element of $A^\Box$ that defines an absolute right lifting of its underlying cospan:

When $A$ admits all pullbacks, the pullback squares can be characterized as those elements of $A^\Box$ at which the component of the unit of the adjunction $\text{res} \dashv \text{ran}$ of Corollary 4.3.5 is an isomorphism; see Exercise 4.3.x. Dually, a pushout square in $A$ is an element of $A^\Box$ that defines an absolute left lifting of its underlying span

i.e., an element at which the component of the counit of the adjunction $\text{lan} \dashv \text{res}$ is an isomorphism. The notion of a family $X \to A^\Box$ of pushout or pullback squares is defined analogously.
The following characterization of pullback squares will prove useful for establishing their basic calculus:

4.3.10. **Lemma** (pullbacks as absolute lifting diagrams). A commutative square in an $\infty$-category $A$ as below-left is a pullback square if and only if the induced 2-cell $(\text{id}_a, v)$ below-right is an absolute right lifting diagram.

The statement requires some explanation. A commutative square $1 \to A$ defines an element of $\text{Fun}(1, A)$, the data of which is given by:

- the four vertices and five 1-simplices in the underlying quasi-category $A_0 := \text{Fun}(1, A)$ of $A$, displayed above-left,
- together with a pair of unnamed 2-simplices that witness commutativity $fu = w = gv$ in $hA := h\text{Fun}(1, A)$.

The 1-simplex $g$ represents a 2-cell $1 \xrightarrow{c} A$, inducing the map $^r g : 1 \to \text{Hom}_A(A, a)$. The map $^r u : 1 \to \text{Hom}_A(A, b)$ is defined similarly. The map $^r f_* : \text{Hom}_A(A, b) \to \text{Hom}_A(A, a)$ is characterized by the pasting diagram

as in Corollary 3.5.11. By Proposition 3.4.7, the composite $^r f_*^r u^*$ is isomorphic to $^r fu^*$. By 2-cell induction, the 2-cell $(\text{id}_a, v) : ^r fu^* \Rightarrow ^r g^*$ displayed above-right may be constructed by specifying its domain and codomain components, the former of which we take to be $1 \xrightarrow{d} A$ and the latter of which we take to be $\text{id}_a$.

**Proof.** By Corollary 4.2.8, the fiber of the restriction functor

$A_{g \triangleright f}^{\sqcup} \longrightarrow A^{\sqcup}$

is equivalent to the $\infty$-category of cones over the cospan diagram $g \triangleright f$. By Proposition 4.3.2, to show that the commutative square defines a pullback diagram is to show that $(u, v, f, g) : 1 \to A_{g \triangleright f}^{\sqcup}$ defines a terminal element. Similarly, by Theorem 3.5.12, the pair $(^r u, (\text{id}_a, v))$ defines an
absolute right lifting diagram if and only if it represents a terminal element in the comma ∞-category $\text{Hom}_{\text{Hom}(A, A)}(f, g)$. We will show that $A_{\text{Hom}(A, A)}^{f, g}$ and $\text{Hom}_{\text{Hom}(A, A)}(f, g)$ are equivalent, which proves the claimed biconditional.

To see this, note that the simplicial square $\Box$ can be formed by gluing two 2-simplices $\Box$ along their diagonal edge, giving rise to the pullback below-left:

\[
\begin{array}{ccc}
A & \to & A^3 \\
\downarrow & & \downarrow p_0 \circ 2 \\
A^3 & \to & A^2
\end{array}
\]

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}(A, A)}(f, g, \text{Hom}(A, a)) & \to & \text{Hom}(A, a)^2 \\
\downarrow & & \downarrow p_0 \\
\text{Hom}(A, b) & \to & \text{Hom}(A, a)
\end{array}
\]

We'll argue that maps in the cospan whose pullback defines the comma ∞-category displayed above-right are each equivalent to pullbacks of the functor $p_0 \circ 2 : A^3 \to A^2$ to suitable fibers.

To see this for $f$, consider the solid-arrow diagram below, which induces the dashed map between the two fibers

\[
\begin{array}{ccc}
A_f & \to & A^3 \\
\downarrow & & \downarrow p_0 \circ 2 \\
A^3 & \to & A^2
\end{array}
\]

\[
\begin{array}{ccc}
\text{Hom}(A, b) & \to & A^2 \\
\downarrow & & \downarrow p_0 \\
\text{Hom}(A, a) & \to & A
\end{array}
\]

Since $A^3 \cong A^{A^2[2]}$, the right-hand back square is equivalent to a pullback. Composing the pullback squares in the back face of the diagram, we obtain an equivalence $A_f \Rightarrow \text{Hom}(A, b)$ and see by inspection that the map $p_f : A_f \Rightarrow \text{Hom}(A, a)$ is equivalent to the map $f^* : \text{Hom}(A, b) \to \text{Hom}(A, a)$. In the map $p_0 \circ 2 : A^3 \to A^2$ pulls back to a map equivalent to $f$, on the fibers over $f$ and $a$ respectively.

By applying $(-)^2$ to the pullback diagram that defines $\text{Hom}(A, a)$ we obtain a pullback square that factors as a composite of two pullbacks:

\[
\begin{array}{ccc}
\bullet & \to & A^3 \cong A^{2 \times 1} \\
\downarrow & & \downarrow p_2 \\
\text{Hom}(A, a)^2 & \to & A^{2 \times 1} \to A^{2 \times 2} \\
\downarrow & & \downarrow p_0 \\
1 & \to & A \\
\downarrow a & & \downarrow \Delta \\
1 & \to & A
\end{array}
\]

By the equivalence $A^{2 \times 1} \cong A^{2 \times 1}$ of Proposition 4.2.7, the left-hand pullback square shows that $\text{Hom}(A, a)^2$ is equivalent to the fiber of $p_2 : A^3 \to A$ along $a : 1 \to A$. Modulo this equivalence, the
domain-projection map $p_0 : \text{Hom}_A(A,a)^2 \to \text{Hom}_A(A,a)$ is equivalent to the map induced from
\[
\begin{array}{ccc}
A^3 & \xrightarrow{p_{02}} & A^2 \\
\downarrow & & \downarrow \\
A & \xrightarrow{p_1} & \text{Hom}_A(A,a) \\
\end{array}
\]
on fibers over $a : 1 \to A$. The codomain-projection $p_1 : \text{Hom}_A(A,a)^2 \to \text{Hom}_A(A,a)$ is similarly equivalent to the pullback of the fibered map $p_{12} : A^3 \to A^2$ over $a : 1 \to A$.

Putting this together, it follows that the comma $\infty$-category $\text{Hom}_{\text{Hom}_A(A,a)}(\text{Hom}_A(A,a), \text{Hom}_A(A,a))$ is equivalently computed by forming the limit of the diagram:
\[
\begin{array}{ccc}
\bullet & \xrightarrow{} & A^0 & \xrightarrow{} & A^3 & \xrightarrow{p_{12}} & A^2 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
1 & \xrightarrow{f} & A^2 \\
\end{array}
\]
The codomain-projection $p_1 : \text{Hom}_{\text{Hom}_A(A,a)}(\text{Hom}_A(A,a), \text{Hom}_A(A,a)) \to \text{Hom}_A(A,a)$ is the pullback of the top-horizontal composite in the above diagram along the inclusion $\text{Hom}_A(A,a) \to A^2$. So we see that the comma $\infty$-category $\text{Hom}_{\text{Hom}_A(A,a)}(\text{Hom}_A(A,a), \text{Hom}_A(A,a))$ is equivalently computed by the limit below-left, which rearranges into the pullback below-right that defines the fiber $A^0 \times_{g \vee f} A^0$, proving the claimed equivalence:
\[
\begin{array}{ccc}
\bullet & \xrightarrow{} & A^0 \\
\downarrow & & \downarrow \\
1 & \xrightarrow{f} & A^2 \\
\end{array}
\]
\[
\begin{array}{ccc}
\bullet & \xrightarrow{} & A^0 & \xrightarrow{} & A^3 & \xrightarrow{p_{12}} & A^2 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
A^0 \times_{g \vee f} A^0 & \xrightarrow{\text{res}} & A^0 \\
\downarrow & & \downarrow \\
1 & \xrightarrow{g \vee f} & A^0 \\
\end{array}
\]

There is a non-identity automorphism of the simplicial set $\mathbb{2} \times \mathbb{2}$, which induces a “transposition” automorphism of $A^0$. By symmetry, a commutative square in $A$ is a pullback if and only if its transposed square is a pullback. This gives a dual form of Lemma 4.3.10 with the roles of $f$ and $g$ and of $u$ and $v$ interchanged. As a corollary, we can easily prove that pullback squares compose both “vertically” and “horizontally” and can be cancelled from the “right” and “bottom”:
4.3.11. **Proposition** (composition and cancelation of pullback squares). Given a composable pair of commutative squares in $A$ and their composite rectangle defined via the equivalence $A^{3 \times 2} \simeq A \boxtimes A^{\square}$

![Diagram]

if the right-hand square is a pullback, then the left-hand square is a pullback if and only if the composite rectangle is a pullback.

**Proof.** By Lemma 4.3.10, we are given an absolute right lifting diagram

$$
\begin{array}{ccc}
\text{Hom}_A(A, c) & \xrightarrow{\gamma} & \text{Hom}_A(A, a) \\
\downarrow^{(\text{id}_a, \gamma)} & & \downarrow^{\delta_a} \\
1 & \xrightarrow{f} & \text{Hom}_A(A, a)
\end{array}
$$

By Lemma 2.4.1, the composite diagram

$$
\begin{array}{ccc}
\text{Hom}_A(A, e) & \xrightarrow{\gamma \gamma} & \text{Hom}_A(A, c) \\
\downarrow^{(\text{id}_c, \gamma)} & & \downarrow^{\delta_c} \\
\text{Hom}_A(A, c) & \xrightarrow{\gamma \gamma} & \text{Hom}_A(A, a)
\end{array}
$$

is an absolute right lifting diagram if and only if the top triangle is an absolute right lifting diagram. By Lemma 4.3.10, this is exactly what we wanted to show. □

4.3.12. **Remark.** The result of Proposition 4.3.11 also holds for $X$- indexed families of commutative squares, by which we mean diagrams $X \to A^{\square}$, or equivalently, elements of $\text{Fun}(X, A)^{\square}$. The proof is the same, making use of a generalization of Lemma 4.3.10 which states that an $X$-indexed commutative square valued in an $\infty$-category $A$ in an $\infty$-cosmos $\mathcal{K}$ as below-left is a pullback square if and only if the induced 2-cell $(\text{id}_a, v)$ below-right is an absolute right lifting diagram in $\mathcal{K}/X$:

![Diagram]

This characterization of $X$-indexed pullback squares can be proven by re-implementing the construction given in the proof of Lemma 4.3.10, using comma $\infty$-categories and simplicial limits in the sliced $\infty$-cosmos $\mathcal{K}/X$, as described in Proposition 1.2.22, in place of the analogous constructions in $\mathcal{K}$.
it not for the more complicated notation involved, we would have presented this general proof instead of its special case above.

Alternatively, this extension can be deduced from the result we’ve already proven. A diagram \( s: X \to A^X \) in \( \mathcal{K} \) also defines a \( X \)-indexed commutative square in the \( \infty \)-cosmos \( \mathcal{K}_{/X} \) valued in \( \pi: A \times X \to X \). This takes the form of a functor \( (s, \text{id}_X): X \to A^X \). It’s easy to verify that a diagram valued in \( \pi: A \times X \to X \) whose component at \( X \) is the identity has a limit in \( \mathcal{K}_{/X} \) if and only if the \( A \)-component of the diagram has a limit in \( \mathcal{K} \). Since \( \text{id}_X \) is the terminal object of \( \mathcal{K}_{/X} \), this object is the \( \infty \)-category \( 1 \in \mathcal{K}_{/X} \), so Lemma 4.3.10 applies in the \( \infty \)-cosmos \( \mathcal{K}_{/X} \) to prove the general case of \( X \)-indexed families of commutative squares in \( \mathcal{K} \).

As discussed in Example 2.3.9, terminal and initial elements are special cases of limits and colimits, respectively, where the diagram shape is empty. For any \( \infty \)-category \( A \), the \( \infty \)-category \( A^\emptyset \cong 1 \) of empty diagrams in \( A \) is terminal. Thus, there is a unique \( \emptyset \)-indexed diagram in \( A \). It follows immediately from the construction of the comma \( \infty \)-categories in Definition 4.2.1, that both of the \( \infty \)-categories of cones over or under the unique empty diagram are isomorphic to \( A \). In the case of cones over an empty diagram, the domain-evaluation functor, carrying a cone to its summit, is the identity on \( A \), while in the case of cones under the empty diagram, the codomain-evaluation functor, carrying a cone to its nadir, is the identity on \( A \). The following characterization of terminal elements can be deduced as a special case of Proposition 4.3.1, though we find it easier to argue from Proposition 4.1.1.

4.3.13. PROPOSITION. An element \( a: 1 \to A \) of an \( \infty \)-category \( A \)

(i) defines a terminal element of \( A \) if and only if the domain-projection functor \( p_0: \text{Hom}_{A}(A, a) \to A \) is a trivial fibration, and

(ii) defines an initial element of \( A \) if and only if the codomain-projection functor \( p_1: \text{Hom}_{A}(a, A) \to A \) is a trivial fibration.

PROOF. Recall from Definition 2.2.1, that an element is terminal if and only if it is right adjoint to the unique functor

\[
1 \xleftarrow{!} A
\]

By Proposition 4.1.1, \( ! \dashv a \) if and only if there is an equivalence \( \text{Hom}_{1}(!, 1) \cong A \text{Hom}_{A}(A, t) \). By the defining pullback (3.4.2) for the comma \( \infty \)-category, the left representation of \( !: A \to 1 \) is \( A \) itself, with domain-projection functor the identity. So the component of the equivalence \( \text{Hom}_{A}(A, a) \cong A \) over \( A \) must be the domain-projection functor \( p_0: \text{Hom}_{A}(A, a) \to A \), and we conclude that \( a \) is a terminal element if and only if this isofibration is a trivial fibration.

4.3.14. DIGRESSION (terminal elements of a quasi-category). In the \( \infty \)-cosmos of quasi-categories, the domain of the isofibration \( p_0: \text{Hom}_{A}(A, a) \to A \) is equivalent over \( A \) to the slice quasi-category \( A_{/a} \), defined in Proposition 4.2.5. Via this equivalence, Proposition 4.3.13 proves that \( a \) is terminal if and only if the projection \( A_{/a} \to A \) is a trivial fibration in the sense of Definition 1.1.24, which transposes to Joyal’s original definition of a terminal element of a quasi-category. See Proposition F.1.1 for an expanded discussion.

Exercises.
4.3.i. **Exercise** (pointwise limits in functor ∞-categories). Suppose $A$ admits the limit $\ell: D \rightarrow A$ of a family of diagrams $d: D \rightarrow A^I$ of shape $I$. Prove that the diagram ∞-category $A^K$ admits limits of the corresponding family of $I$-shaped diagrams $d^K: D^K \rightarrow (A^K)^I \cong (A^K)^I$ defined “pointwise in $K$” by the functor $\ell^K: D^K \rightarrow A^K$. This gives a considerably simplified proof of a slightly weaker version of Proposition 2.4.11.

4.3.ii. **Exercise.** State and prove versions of Proposition 4.3.4 and Corollary 4.3.5 that apply to a family of diagrams $d: D \rightarrow A^I$ indexed by an ∞-category $I$ in a cartesian closed ∞-cosmos.

4.3.iii. **Exercise.** Let $a$ be an element of an ∞-category $A$ and let $K$ and $L$ be simplicial sets. Prove that if $A$ has tensors and cotensors then these operations are associativity in the sense that the elements

$$K \otimes (L \otimes a) \cong (K \times L) \otimes a \cong L \otimes (K \otimes a) \quad \text{and} \quad (a^L)^K \cong a^{K \times L} \cong (a^K)^L$$

are isomorphic.

4.3.iv. **Exercise.** Prove that if $A$ has a terminal element $t$ then for any element $a$ the mapping space $\text{Hom}_A(a, t)$ is contractible, i.e., is equivalent to the terminal ∞-category $1$.

4.3.v. **Exercise.** Suppose $A$ admits pullbacks and consider a family of commutative squares $d: D \rightarrow A^\square$. Show that the following are equivalent:

(i) The commutative triangle

$$\begin{array}{ccc}
\square & \xrightarrow{\text{res}} & \square \\
\downarrow d & & \downarrow \text{res} \\
\square & \xrightarrow{\text{res} d} & A^\square
\end{array}$$

is an absolute right lifting diagram.

(ii) The component of the unit of the adjunction $\text{res} \dashv \text{ran}$

$$\begin{array}{ccc}
\square & \xrightarrow{d} & A^\square \\
\downarrow \text{res} & & \downarrow \eta \text{ran} \\
\square & \xrightarrow{\text{ran}} & A^\square
\end{array}$$

is invertible.

4.3.vi. **Exercise.** Prove that a square in $A$ is a pullback if and only if its “transposed” square, defined by composing with the involution $A^\square \cong A^\square$ induced from the automorphism of $2 \times 2$ that swaps the “off-diagonal” elements, is a pullback square.

4.3.vii. **Exercise.** Suppose $A$ has pullbacks and a terminal element. Show that $A$ admits binary products.

---

Footnotes:

³If $K$ is an ∞-category in a cartesian closed ∞-cosmos this can be proven directly by arguing in the homotopy 2-category, but another proof applies simultaneously to this case and to the case where $K$ is a simplicial set: use the fact that the cosmological functor $(-)^K: K \rightarrow K$ preserves the equivalence of Proposition 4.3.1.

⁴The converse implication holds in ∞-cosmoi of (∞, 1)-categories, as argued in the proof of Proposition F.1.1.
4.4. Pointed and Stable ∞-Categories

In this section we study ∞-categories with special exactness properties, admitting certain finite limit and colimit constructions, which coincide.

4.4.1. Definition (pointed ∞-category). An ∞-category $A$ is **pointed** if it admits a zero element: an element $*: 1 \to A$ that is both initial and terminal.

Recall Lemma 2.2.2, which enumerates the data required to present an initial or terminal element. To show that an element $*: 1 \to A$ defines a zero element it suffices to define a pair of natural transformations $\rho: *! \Rightarrow \text{id}_A$ and $\xi: \text{id}_A \Rightarrow *!$ so that the components $\rho_*: * \Rightarrow *$ and $\xi_*: * \Rightarrow *$ are isomorphisms in $hA$. Here $\rho$ is the counit of the adjunction $* \dashv !$ that witnesses the initiality of the zero element and $\xi$ is the unit of the adjunction $! \dashv *$ that witnesses the terminality of the zero element.

The counit $\rho$ is represented by a functor $\downarrow\rho: A \to A^2$, whose domain-component is constant at $*$ and whose codomain-component is $\text{id}_A$, that we refer to as the family of points of $A$. Dually, the unit $\xi$ is represented by a functor $\downarrow\xi: A \to A^2$, whose domain-component is $\text{id}_A$ and whose codomain-component is constant at $*$, that we refer to as the family of copoints.

4.4.2. Lemma (pointed ∞-categories of based elements). If $A$ is an ∞-category with a terminal element $t: 1 \to A$ then the ∞-category $\text{Hom}_A(t, A)$ is pointed, with $\downarrow\text{id}_t$ serving as its zero element. Moreover all pointed ∞-categories arise in this manner.

Proof. If $A$ is a pointed ∞-category with zero element $*: 1 \to A$ then by Proposition 4.3.13, $p_1: \text{Hom}_A(*, A) \Rightarrow A$ defines an equivalence between $A$ and an ∞-category of the form described in the statement. Since the codomain-projection functor $p_1$ carries the element $\downarrow\text{id}_*$ of $\text{Hom}_A(*, A)$ to the zero element of $A$, Lemma 2.2.7 tells us that $\downarrow\text{id}_*$ must define a zero element of $\text{Hom}_A(*, A)$.

Now suppose only that $A$ has a terminal element $t: 1 \to A$. By Corollary 3.5.10, we know that $\downarrow\text{id}_t$ defines an initial element of $\text{Hom}_A(t, A)$, so it remains only to show that this element is also terminal. By Lemma 2.2.2, our task is to define a natural transformation $\eta: \downarrow\text{id}_t \Rightarrow \text{id}_{\text{Hom}_A(t, A)}$ witnessing the terminality of $\downarrow\text{id}_t$. By Proposition 3.4.6, we may use 2-cell induction to induce $\eta$ from a pair of natural transformations $(p_1\tau, p_0\tau)$ satisfying a compatibility condition. Here necessarily $p_0\tau = \text{id}_t$, since its codomain ∞-category is terminal, and we define $p_1\tau$ to be $\xi p_1$, where $\xi$ is the unit of the adjunction $! \dashv t$. The compatibility condition of Proposition 3.4.6(ii) follows from the triangle equality relation $\xi t = \text{id}_t$.

Now the component $\eta_{\text{id}_t}$ is induced from the pair of identity 2-cells $(\xi_t, \text{id}_t)$, so by 2-cell conservativity we conclude that $\eta_{\text{id}_t}$ is invertible. By Exercise 2.2.i, this is enough to witness the terminality of $\downarrow\text{id}_t$. 

Pointed ∞-categories permit a number of constructions that are familiar from homotopy theory. By Definition 4.3.8, gluing two copies of the family of points $\downarrow\rho: A \to A^2$ along their codomain defines a diagram $\hat{\rho} := \downarrow\rho \vee \downarrow\rho: A \to A^2$. Dually, there is a diagram $\hat{\xi} := \downarrow\xi \wedge \downarrow\xi: A \to A^2$ defined by gluing the family of copoints $\downarrow\xi: A \to A^2$ to itself along their domains.
4.4.3. Definition (loops and suspension). A pointed $\infty$-category $A$ admits loops if it admits a limit of the family of diagrams

$$
\begin{array}{ccc}
A & \xrightarrow{\Omega} & A \\
\downarrow & & \downarrow_{\Delta} \\
A & \xrightarrow{\rho} & A^\omega
\end{array}
$$

in which case the limit functor $\Omega: A \to A$ is called the loops functor. Dually, a pointed $\infty$-category $A$ admits suspensions if it admits a colimit of the family of diagrams

$$
\begin{array}{ccc}
A & \xleftarrow{\Sigma} & A \\
\uparrow & & \uparrow_{\Lambda} \\
A & \xleftarrow{\xi} & A^\pi
\end{array}
$$

in which case the colimit functor $\Sigma: A \to A$ is called the suspension functor.

Importantly, if $A$ admits loops and suspensions, then the loops and suspension functors are adjoint:

4.4.4. Proposition (the loops-suspension adjunction). If $A$ is a pointed $\infty$-category that admits loops and suspensions, then the loops functor is right adjoint to the suspension functor

$$
A \xleftarrow{\Sigma} \xrightarrow{\Omega} A
$$

The main idea of the proof is easy to describe. If $A$ admits all pullbacks and all pushouts, then Corollary 4.3.5 supplies adjunctions

$$
\begin{array}{ccc}
A^\omega & \xleftarrow{\text{res}} & A \\
\text{ran} & & \text{ran} \\
A & \xrightarrow{\text{lau}} & A^\pi
\end{array}
$$

that are fibered over $A \times A$ upon evaluating at the intermediate vertices of the commutative square. By pulling back along $(\ast, \ast): 1 \to A \times A$, we can pin these vertices at the zero element. Since the zero element is initial and terminal, the $\infty$-categories of pullback and pushout diagrams of this form are both equivalent to $A$ and the pulled-back adjoints now coincide with the loops and suspension functors.

The only subtlety in the proof that follows is that we have assumed weaker hypotheses: that $A$ admits only loops and suspensions, but perhaps not all pullbacks and pushouts.
PROOF. The diagram \( \tilde{\rho} \) lands in a subobject \( A^{\circ}_{\ast} \) of \( A^{\circ} \) defined below-left that is comprised of those cospans whose source elements are pinned at the zero element \( \ast \) of \( A \).

\[
\begin{array}{c}
\xymatrix{
A \ar[rr]^\rho \ar[dr]_{\tilde{\rho}} & & A^\circ \\
1 \ar[r]_{(\ast, \ast)} & A \times A}
\end{array}
\quad \quad \quad \quad \quad \quad
\begin{array}{c}
\xymatrix{
A \ar[rr]^\rho \ar[dr]_{\tilde{\rho}^*} & & \text{Hom}_A(\ast, A) \\
\ast \ar[r]_{p_1} & A}
\end{array}
\]

From a second construction of \( A^{\circ}_{\ast} \) displayed above-right and the characterization of initiality given in Proposition 4.3.13, we may apply the 2-of-3 property of equivalences to conclude first that the family of points \( \hat{\rho}^* : A \to A^2 \) restricts to define an equivalence \( \hat{\rho}^* : A \Rightarrow \text{Hom}_A(\ast, A) \) and then that the induced diagram \( \hat{\rho}_{\ast} : A \Rightarrow A^{\circ}_{\ast} \) is an equivalence. Dually, the diagram \( \hat{\xi} : A \to A^\circ \) defines an equivalence \( \hat{\xi}^* : A \Rightarrow A^\circ_{\ast} \) when its codomain is restricted to the subobject of spans whose target elements are pinned at the zero element \( \ast \).

By Proposition 4.3.4, a pointed \( \infty \)-category \( A \) admits loops or admits suspensions if and only if there exist absolute lifting diagrams as below-left and below-right respectively

\[
\begin{array}{c}
\xymatrix{
A \ar[rr]^\rho \ar[dr]_{\tilde{\rho}} & & A^\circ \\
\ast \ar[r]_{\text{res}} & \text{Hom}_A(\ast, A) \ar[r]_{\text{ran}} & A}
\end{array}
\quad \quad \quad \quad \quad \quad
\begin{array}{c}
\xymatrix{
A \ar[rr]^\rho \ar[dr]_{\tilde{\rho}} & & A^\circ \\
\ast \ar[r]_{\text{res}} & \text{Hom}_A(\ast, A) \ar[r]_{\text{ran}} & A}
\end{array}
\]

and moreover we may take these natural isomorphisms to be identities. Doing so allows us to define restricted lifts

\[
\begin{array}{c}
\xymatrix{
A^{\circ}_{\ast} \ar[rr]^\rho_{\ast} \ar[dr]_{\text{res}_{\ast}} & & A^{\circ} \\
A \ar[r]_{\text{res}} & \text{Hom}_A(\ast, A) \ar[r]_{\text{ran}_{\ast}} & A^{\circ}_{\ast}}
\end{array}
\quad \quad \quad \quad \quad \quad
\begin{array}{c}
\xymatrix{
A^{\circ}_{\ast} \ar[rr]^\rho_{\ast} \ar[dr]_{\text{res}_{\ast}} & & A^{\circ} \\
A \ar[r]_{\text{res}} & \text{Hom}_A(\ast, A) \ar[r]_{\text{ran}_{\ast}} & A^{\circ}_{\ast}}
\end{array}
\]

which we will argue again define absolute right and left lifting diagrams respectively. The right- and left-handed arguments are dual, so we focus our attention on the former. By Theorem 3.5.3 the absolute right lifting diagram defines a fibered equivalence \( \text{Hom}_{A^{\circ}_{\ast}}(A^{\circ}_{\ast}, \text{ran}_{\ast}) \simeq_{A \times A^{\circ}_{\ast}} \text{Hom}_{A^{\circ}_{\ast}}(\text{res}_{\ast}, \tilde{\rho}) \), which may be pulled back along the inclusion of the subobject \( A^{\circ}_{\ast} \hookrightarrow A^{\circ} \) of commutative squares in \( A \) whose intermediate vertices are pinned at the zero element to yield a fibered equivalence over \( A \times A^{\circ}_{\ast} \). We shall argue that the comma \( \infty \)-categories pull back to \( \infty \)-categories that are equivalent to \( \text{Hom}_{A^{\circ}_{\ast}}(A^{\circ}_{\ast}, \text{ran}_{\ast}) \) and \( \text{Hom}_{A^{\circ}_{\ast}}(\text{res}_{\ast}, \tilde{\rho}_{\ast}) \), respectively.
To see this, first observe that the universal property of the zero element implies that $\text{Hom}_A(*)$ is contractible and therefore the outer rectangle is equivalent to the pullback

\[
\begin{array}{ccc}
\text{id}_A & \to & \text{Hom}_A(\ast, \ast) \\
\downarrow & & \downarrow p_1 \\
\ast & \to & A \times 1 \\
\downarrow & & \downarrow \text{id}_A \times \ast \\
1 & \to & A \times A
\end{array}
\]

It follows that since the top and bottom faces of the commutative prism are strict pullbacks

\[
\begin{array}{ccc}
(A \supseteq) & \to & (A \supseteq)^2 \\
\downarrow \text{res} & & \downarrow \text{res} \\
A \supseteq \times A \supseteq & \to & A\supseteq \times A\supseteq \\
\downarrow \text{res} \times \text{res} & & \downarrow \text{res} \times \text{res} \\
A_{\ast} \times A_{\ast} & \to & A_{\ast} \times A_{\ast}
\end{array}
\]

then the left and middle vertical faces are also pullbacks up to equivalence. We use the latter of these and the commutative cube

\[
\begin{array}{ccc}
\text{Hom}_{A_{\ast}}(\text{res}, \bar{\rho}) & \to & (A_{\ast})^2 \\
\downarrow \text{res}_{\ast} & & \downarrow \text{res}_{\ast} \\
A \times A_{\ast} & \to & A\ast \times A\ast \\
\downarrow \bar{\rho} \times \text{res}_{\ast} & & \downarrow \bar{\rho} \times \text{res}_{\ast} \\
A_{\ast} \times A_{\ast} & \to & A_{\ast} \times A_{\ast}
\end{array}
\]

to conclude that the comma $\infty$-category $\text{Hom}_{A_{\ast}}(\text{res}, \bar{\rho})$ pulls back along the inclusion $A_{\ast} \hookrightarrow A$ to an $\infty$-category that is equivalent to $\text{Hom}_{A_{\ast}}(\text{res}, \bar{\rho}_{\ast})$, as claimed. Similarly, from the former pullback up to equivalence, we conclude that $\text{Hom}_{A_{\ast}}(A \supseteq, \text{ran})$ pulls back to an $\infty$-category that is equivalent to $\text{Hom}_{A_{\ast}}(A \supseteq, \text{ran}_{\ast})$.

In this way we obtain fibered equivalences

\[
\text{Hom}_{A_{\ast}}(A \supseteq, \text{ran}) \cong A_{\ast} \times A_{\ast} \text{ and } \text{Hom}_{A_{\ast}}(\text{lan}_{\ast}, A \supseteq) \cong A_{\ast} \times A_{\ast}
\]

By Theorem 3.5.8 these encode absolute liftings of $\bar{\rho}_{\ast}$ and $\hat{\xi}_{\ast}$ through the restriction functors:

\[
\begin{array}{ccc}
A_{\ast} & \to & A_{\ast} \\
\text{ran}_{\ast} & \text{res}_{\ast} & \text{ran}_{\ast} \\
A_{\ast} & \to & A_{\ast}
\end{array}
\]

Restricting along the inverse equivalences $A_{\ast} \to A$ and $A_{\ast} \to A$ to $\bar{\rho}_{\ast}$ and $\hat{\xi}_{\ast}$ and pasting with the invertible 2-cell we obtain absolute lifting diagrams whose bottom edge is the identity.
By Lemma 2.3.6, these lifting diagrams define adjunctions:

\[
\begin{array}{ccc}
A \cong A^\square & \perp & A^\square \\
\downarrow^{\text{ran}_s} & & \downarrow^{\text{ran}_s} \\
\cong A^\square & \perp & A^\square \\
\end{array}
\]

which compose to the desired adjunction \( \Sigma \dashv \Omega \). \( \square \)

4.4.5. Definition (fiber and cofiber). An arrow \( f : 1 \to A^2 \) from \( x \) to \( y \) in a pointed \( \infty \)-category \( A \) admits a fiber if \( A \) admits a pullback of the cospan formed by \( f \) and the component \( \rho_y \) of the family of points. The pullback square defined by the absolute right lifting diagram

\[
\begin{array}{ccc}
& & A^\square \\
\downarrow^{\text{fib}} & & \downarrow^{\text{res}} \\
1 & \xrightarrow{\rho_y \vee f} & A^\square \\
\end{array}
\]

is referred to as the fiber sequence for \( f \). Dually, \( f \) admits a cofiber if \( A \) admits a pushout of the span formed by \( f \) and the component \( \xi_x \) of the family of copoints, in which case the pushout square

\[
\begin{array}{ccc}
& & A^\square \\
\downarrow^{\text{cofib}} & & \downarrow^{\text{res}} \\
1 & \xrightarrow{\xi_x \wedge f} & A^\square \\
\end{array}
\]

defines the cofiber sequence for \( f \).

Fiber and cofiber sequences define commutative squares in \( A \)

\[
\begin{array}{ccc}
\text{fib}(f) & \to & x \\
\downarrow & & \downarrow \quad f \\
* & \to & y \\
\end{array}
\]

whose lower-left vertex is the zero element \( * \). The data of such squares is given by a commutative triangle in \( A \)—an element of \( A^3 \)—together with a nullhomotopy of the diagonal edge—a witness that this edge factors through the zero element in \( \mathbf{h}A \). A commutative square in \( A \) whose lower-left vertex is the zero element is referred to as a triangle in \( A \).

We can now state the first of several equivalent characterizations of stable \( \infty \)-categories. This notion and the results that follow are due to Jacob Lurie first appearing in a preprint [76] later incorporated into the first chapter of Higher Algebra [77].

4.4.6. Definition (stable \( \infty \)-category). A stable \( \infty \)-category is a pointed \( \infty \)-category \( A \) in which

(i) every morphism admits a fiber and a cofiber: that is, there exist absolute lifting diagrams

\[
\begin{array}{ccc}
A^2 & \xrightarrow{\rho_{\text{cod}} \vee \text{id}} & A^\square \\
\downarrow^{\text{fib}} & & \downarrow^{\text{res}} \\
A^\square & \xrightarrow{\xi_{\text{dom}} \wedge \text{id}} & A^\square \\
\end{array}
\]
(ii) and a triangle in \( A \) defines a fiber sequence if and only if it also defines a cofiber sequence. Such triangles are called **exact triangles**.

As a means of familiarizing ourselves with this definition, we prove:

4.4.7. **Lemma.** Let \( A \) be a stable \( \infty \)-category and let \( J \) either be a simplicial set or another \( \infty \)-category in the case where the ambient \( \infty \)-cosmos \( \mathcal{K} \) is cartesian closed. Then \( A^J \) is again a stable \( \infty \)-category.

**Proof.** By Proposition 2.1.7, the cosmological functor \( (-)^J: \mathcal{K} \to \mathcal{K} \) preserves the adjunctions

\[
\begin{array}{ccc}
A & \xrightarrow{!} & 1 \\
\downarrow & & \downarrow \\
\ast & \Rightarrow & \ast
\end{array}
\quad \Rightarrow 
\begin{array}{ccc}
A^J & \xrightarrow{!^J} & 1^J \cong 1 \\
\downarrow & & \downarrow \\
\ast^J & \Rightarrow & \ast^J
\end{array}
\]

that exhibit the universal properties of the zero element \( \ast: 1 \to A \). Thus, we see that \( A^J \) is a pointed \( \infty \)-category, whose basepoint is the constant \( J \)-shaped functor valued at \( \ast \).

Similarly, by Corollary 3.5.7, the cosmological functor \( (-)^J: \mathcal{K} \to \mathcal{K} \) preserves the absolute lifting diagrams of 4.4.6(i) that define fiber and cofiber sequences. Since \( res^J: (A^\Box)^J \to (A^\Box)^J \) is isomorphic to \( res: (A^\Box) \to (A^\Box)^\Box \) and similarly for the functor restricting from a square to its underlying span, these absolute lifting diagrams define fiber and cofiber sequences in \( A^J \).

Finally, condition 4.4.6(ii) can be re-expressed as the assertion that the commutative triangle below-left is absolute left lifting and the triangle below-right is absolute right lifting:

\[
\begin{array}{ccc}
A & \xrightarrow{!} & 1 \\
\downarrow & & \downarrow \\
\ast & \Rightarrow & \ast
\end{array}
\quad \Rightarrow 
\begin{array}{ccc}
A^J & \xrightarrow{!^J} & 1^J \cong 1 \\
\downarrow & & \downarrow \\
\ast^J & \Rightarrow & \ast^J
\end{array}
\]

which is to say that fiber sequences in \( A \) are also cofiber sequences and cofiber sequences in \( A \) are also fiber sequences. By applying Corollary 3.5.7 once more, we see that the same exactness property holds in \( A^J \). Thus \( A^J \) is stable. \( \square \)

In fact, as the next result reveals, stable \( \infty \)-categories admit all pushouts and all pullbacks, and such squares coincide. Squares that are both pushouts and pullbacks are called **exact squares**.

4.4.8. **Proposition** (pullbacks and pushouts in stable \( \infty \)-categories). A stable \( \infty \)-category admits all pushouts and all pullbacks, and moreover, a square is pushout if and only if it is a pullback.

**Proof.** Given a generic cospan \( g \vee f: X \to A^\Box \) in \( A \), form the cofiber of \( f \) followed by the fiber of the composite map \( c \to a \to \text{cofib} f \):

\[
\begin{array}{ccc}
A^\Box & \xrightarrow{\text{res}} & A^\Box \\
\downarrow & & \downarrow \\
\text{cofib} & \Rightarrow & \ast
\end{array}
\quad \Rightarrow 
\begin{array}{ccc}
A^\Box & \xrightarrow{\text{res}} & A^\Box \\
\downarrow & & \downarrow \\
\text{cofib} & \Rightarrow & \ast
\end{array}
\]

By Definition 4.4.6(ii), the cofiber sequence \( b \to a \to \text{cofib}(f) \) is also a fiber sequence. By the pullback cancelation result of Proposition 4.3.11, we conclude that \( \text{fib}(gq) \) computes the pullback of the cospan \( g \vee f \).

\[ (4.4.9) \]
To see that this pullback square is also a pushout, form the fiber of the map $v$:

$$\begin{array}{ccc}
\text{fib}(v) & \longrightarrow & \text{fib}(qg) \\
\downarrow & & \downarrow \\
\ast & \longrightarrow & c \\
\end{array} \xrightarrow{u} \begin{array}{ccc}
b & \longrightarrow & b \\
\downarrow f & & \downarrow f \\
a & \longrightarrow & a \\
\end{array}$$

By the pullback composition result of Proposition 4.3.11, $\text{fib}(v)$ is also the fiber of the map $f$. By Definition 4.4.6(ii), the fiber sequences $\text{fib}(v) \rightarrow \text{fib}(qg) \rightarrow c$ and $\text{fib}(v) \rightarrow b \rightarrow a$ are also cofiber sequences. Now by the pushout cancellation result of Proposition 4.3.11, we see that the right-hand pullback square is also a pushout square. A dual argument proves that pushouts exist and coincide with pullbacks. □

4.4.10. Digression (on the use of generalized elements to define functors). The first paragraph of the proof just given takes a generic cospan and constructs a rectangular diagram, to which Proposition 4.3.11 can be applied. By the Yoneda lemma, a construction given as a mapping on generalized elements defines an arrow internally to the $\infty$-cosmos, in this case taking the form of a functor $A^a \rightarrow A^3 \times 2$, as we now illustrate by unpacking each of the steps. First, we build, from the generic cospan, the dashed arrow below-left, which forms a diagram that glues this cospan to the cofiber sequence associated to one of its legs:

The simplicial set $\Box \cong \ast \cup \Box$ doesn’t include the composite 1-simplex from the lower-left vertex to the lower-right vertex but this can be attached by filling an inner horn, resulting in an equivalent $\infty$-category we also denote by $A^\Box$. Now we can attach the fiber sequence associated to that composite arrow, gluing the exterior rectangle onto the diagram of shape $\Box$, defining the dashed arrow above-right.

The simplicial set $\Box$ is a subset of the rectangle diagram shape $3 \times 2$. In the notation of (4.4.9) what is missing is the map $u$ and the left-hand square, which we induce by the universal property of the fiber sequence $b \rightarrow a \rightarrow \text{cofib}(f)$, which is expressed by saying that the identity defines an absolute right lifting diagram as below-left. There is a functor $(g, \text{id}, \text{id}) : \ast \times 2 \rightarrow \Box$ inducing the 2-cell below-center, which then factors as below-right:

$$A^\Box \\
\downarrow \Rightarrow \downarrow \downarrow = \downarrow$$

This natural transformation can be encoded by a functor $A^a \rightarrow A^\Box \times 2$ that restricts along $3 \times 2 \hookrightarrow \Box \times 2$ to define a functor $A^a \rightarrow A^3 \times 2$ that builds the diagram on display in (4.4.9).
A stable $\infty$-category admits loops and admits suspensions, formed by taking fibers of the arrows in the family of points and cofibers of arrows in the family of copoints respectively.

4.4.11. **Proposition** (loops and suspension in stable $\infty$-categories). If $A$ is a stable $\infty$-category, the loops and suspension functors define inverse adjoint equivalences

\[
\Sigma \\ A \\ \sim \\ \perp \\ \Omega
\]

Squares that are both pullbacks and pushouts are called **exact squares**.

**Proof.** In the proof of Proposition 4.4.4, the adjunction $\Sigma \dashv \Omega$ is constructed as a composite of adjunctions

\[
\begin{aligned}
A & \cong A^\square \\
& \leftarrow \downarrow \perp \\
& \downarrow \leftarrow \downarrow \Omega
\end{aligned}
\]

that construct fiber and cofiber sequences. By Proposition 2.1.9, the unit and counit of this composite adjunction are given by

\[
\begin{aligned}
A & \cong A^\square \\
& \leftarrow \downarrow \perp \\
& \downarrow \leftarrow \downarrow \Omega
\end{aligned}
\]

By Definition 4.3.9, the unit of $\text{res} \dashv \text{ran}$ restricts to an isomorphism on the subobject of pushout squares. In a stable $\infty$-category, the cofiber sequences in the image of $\text{lan}: A \to A^\square_*$ are pullback squares, so this tells us that $\eta_{\text{lan}}$ is an isomorphism. Dually, the fiber sequences in the image of $\text{ran}: A \to A^\square_*$ are pushout squares, which tells us that $\epsilon_{\text{ran}}$ is an isomorphism. Hence, the unit and counit of $\Sigma \dashv \Omega$ are invertible, so these functors define an adjoint equivalence. \qed

The results just proven suggest several equivalent characterizations of stable $\infty$-categories. The equivalence of condition (iii) is due to Groth [47, §3], who works in the closely related setting of stable derivators and also discusses further equivalent conditions not mentioned here. The remaining equivalences are established by Lurie in [76]. The proof that (iv)$\Rightarrow$(i) is an adaptation of a clever argument of Harpaz appearing as [49, 2.4].

4.4.12. **Theorem** (equivalent characterizations of stable $\infty$-categories). In a pointed $\infty$-category $A$ the following are equivalent, and characterize the class of stable $\infty$-categories:

(i) $A$ admits fibers and cofibers, and fiber and cofiber sequences coincide.

(ii) $A$ admits pullbacks and pushouts, and pullback and pushout squares coincide.

(iii) $A$ admits pullbacks and pushouts, and the pullback functor $\lim: A^\square \to A$ preserves pushouts while the pushout functor $\colim: A^\square \to A$ preserves pullbacks.

(iv) $A$ admits cofibers and the suspension functor is an equivalence.

(v) $A$ admits fibers and the loops functor is an equivalence.
Proof. Proposition 4.4.8 proves (i)⇔(ii), while Proposition 4.4.11 proves that (i)⇒(iv) and (i)⇒(v). So it remains to prove (ii)⇔(iii) as well as the converses of these latter implications, which are dual.

Assuming (ii), we may apply Lemma 4.4.7 to see that the diagram ∞-categories \(A^a\) and \(A^r\) are stable. In particular, \(\lim\colon A^a \to A\) and \(\colim\colon A^r \to A\) are functors between stable ∞-categories that preserve all limits and all colimits, respectively, by virtue of Theorem 2.4.2. Since pushout and pullback squares coincide, we see that pushouts are preserved by the pullback functor and pullbacks are preserved by the pushout functor, proving (iii).

Now assume (iii). By Exercise 3.6.iv to say that the pushout functor preserves pullbacks is equally to say that the functor \(\text{lan}_\odot\colon (A^r)\odot \to (A^\square)\odot\) preserves pullbacks, meaning that the left-hand composite is isomorphic to the right-hand absolute right lifting diagram:

\[
\begin{array}{c}
(A^r)^a \\
\downarrow_{\text{ran}} \\
\downarrow_{\text{res}} \\
\end{array}
\xrightarrow{\text{lan}^a} 
\begin{array}{c}
(A^\square)^a \\
\downarrow_{\text{res}} \\
\end{array}
\cong
\begin{array}{c}
(A^r)^a \\
\downarrow_{\text{ran}} \\
\downarrow_{\text{res}} \\
\end{array}
\xrightarrow{\text{lan}^a} 
\begin{array}{c}
(A^\square)^a \\
\end{array}
\]

To see that any pullback square in \(A\) is also a pushout square, consider the diagram \(\psi\colon (A^a)^a \to (A^x)^a\) depicted below-left, that expands a cospan \(a \to c \leftarrow b\) to a cospan of spans by restricting along an appropriate functor \(r \times \omega \to \omega\) that sends five elements to the terminal vertex of \(r\) and two elements apiece to the remaining two vertices.

By Exercise 2.3.iv, when we compose with \(\text{lan}^a\colon (A^r)^a \to (A^\square)^a\) we obtain the diagram above-right in which each of the dashed squares are pushouts. By Exercise 4.3.i, the functor \(\text{ran}^a\colon (A^\square)^a \to (A^\square)^a\) is naturally isomorphic to the functor \(\text{ran}^\omega\colon (A^a)^\omega \to (A^a)^\omega\). Thus, composing with this functor forms
the pullback of the dotted cospans, which by Exercise 2.3.iv yields the diagram

where \( p \) is the pullback of the original span \( a \to c \leftarrow b \). On account of the natural isomorphism \( \text{lan}^{\mathbf{m}} \circ \text{ran} \cong \text{ran} \circ \text{lan}^{\mathbf{m}} \) this diagram is also produced by first forming the pullbacks of the dotted spans and then taking the pushouts of each cospan. In this way we see that the solid-arrow pullback square above-left is also a pushout. The dual construction completes the proof that (iii) \( \Rightarrow \) (ii).

It remains to prove (iv) \( \Rightarrow \) (i). Assuming (iv), the first task is to show that any cofiber sequence \( d: D \to A^{\mathbf{m}} \) is also a fiber sequence, which is to say the diagram

is absolute right lifting, where the 2-cell arises from the functor \( \mathcal{J} \times \mathbb{Z} \to \mathbf{m} \) that defines the canonical cone induced by a commutative square over its underlying cospan. By Theorem 3.5.3, to show that this diagram is absolute right lifting, it suffices to show that the induced map defines a fibered equivalence \( \text{Hom}_{A}(A,d_{\perp}) \cong_{D \times A} \text{Hom}_{A^{\mathbf{m}}}(\Delta, d_{\perp}) \). Since \( \Sigma: A \to A \) is an equivalence, by Proposition 3.4.5 the maps of cospans

induce equivalences of comma \( \infty \)-categories over \( D \times A \) displayed vertically below:

\[
\begin{align*}
\text{Hom}_{A}(A,d_{\perp}) & \longrightarrow \text{Hom}_{A^{\mathbf{m}}}(\Delta, d_{\perp}) \\
\Sigma \downarrow & \cong \downarrow \Sigma^{d} \\
\text{Hom}_{A}(\Sigma, \Sigma d_{\perp}) & \longrightarrow \text{Hom}_{A^{\mathbf{m}}}(\Delta \Sigma, \Sigma d_{\perp})
\end{align*}
\]

Our task will be to define the dashed diagonal morphism in such a way that we may apply Proposition 3.4.11 to argue that the diagram commutes up to fibered isomorphism. By the 2-of-6 property of the equivalences in an \( \infty \)-cosmos—see Remark 1.2.21 and Exercise 1.4.iv—it follows that the top horizontal map defines a fibered equivalence witnessing the fact that the cofiber sequence is also a fiber sequence.
To explain the construction of this map, it will be helpful to give names to the generalized elements in the cofiber sequence $d: D \to A^\square$ as depicted in the square below-left:

$$
\begin{array}{ccc}
  a & \longrightarrow & b \\
  \downarrow & & \downarrow r \\
  * & \longrightarrow & c \\
\end{array}
$$

Here "a" represents the generalized element $d_\bot$. Since the cofiber sequence $a \to b \to c$ defines a pushout square, when we restrict to its right-hand edge $b \to c$ and form the cofiber, the resulting element is isomorphic to the suspension $\Sigma a$ by Proposition 4.3.11. In particular, we have an absolute left lifting diagram of the following form:

$$
\begin{array}{ccc}
  D & \longrightarrow & A^\square \\
  \downarrow & & \downarrow \text{res} \\
  A^\omega & \longrightarrow & A^2 \\
\end{array}
$$

the 2-cell component of which is represented by a functor

$$
\begin{array}{ccc}
  D & \longrightarrow & A^\omega \times 2 \\
  \downarrow \phi^z & & \downarrow (\text{res}, \text{ev} \bot) \\
  D \times A & \longrightarrow & A^\omega \times A \\
\end{array}
$$

By Proposition 4.2.7, the comma $\infty$-category $\text{Hom}_{A^\omega}(\Delta, d_\bot)$ is equivalent to the pullback

$$
\text{Hom}_{A^\omega}(\Delta, d_\bot) \xrightarrow{\phi^z} A^\square
$$

Here the map $\phi^z$ encodes a square of the form below-left, where "z" represents the generalized element $p_0$ of $A$

$$
\begin{array}{ccc}
  z & \longrightarrow & b \\
  \downarrow & & \downarrow \\
  * & \longrightarrow & c \\
\end{array}
$$

which we may extend to a diagram as above-right by gluing on the square defined by the functor of co-points:
The diagrams $\mu$ and $\lambda$ glue together to form a diagram $\text{Hom}_{A^\infty}(\Delta, d_\sigma) \to A^\infty \times \mathcal{I}$ as below

\[ \begin{array}{ccc}
* & \leftarrow & z \quad \xrightarrow{\sim} \quad * \\
\downarrow & & \downarrow \\
 c & \leftarrow & b \quad \xrightarrow{\sim} \quad * \\
\downarrow & & \downarrow \\
 \Sigma a & = & \Sigma a \quad \xrightarrow{\sim} \quad \Sigma a \\
\end{array} \]

from which we extract a composite map of cospans defining the 2-cell below-left:

\[
\begin{array}{cccccc}
\text{Hom}_{A^\infty}(\Delta, d_\sigma) & \xrightarrow{p_1} & D & \xrightarrow{d_\perp} & A & \xrightarrow{\Sigma} & A \\
p_0 & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
A & \xrightarrow{\xi} & A^\infty \\
\end{array} =
\begin{array}{cccccc}
\text{Hom}_{A^\infty}(\Delta, d_\sigma) & \xrightarrow{p_1} & D & \xrightarrow{d_\perp} & A & \xrightarrow{\Sigma} & A \\
p_0 & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
A & \xrightarrow{\xi} & A^\infty \\
\end{array}
\]

This factors through the absolute left lifting diagram of Definition 4.4.3 defining a natural transformation $\zeta$. By 1-cell induction, this then defines the sought-for map $\zeta^* : \text{Hom}_{A^\infty}(\Delta, d_\sigma) \to \text{Hom}_{A^\infty}(\Sigma, \Sigma d_\perp)$ over $D \times A$, which by applying the 2-of-6 property completes the proof that the cofiber sequence $a \to b \to c$ is also a fiber sequence.

Now to show that every arrow $f : a \to b$ admits a fiber, start by forming its cofiber. Since $\Sigma$ is an equivalence, there exists some element $k$ of $A$ so that $\text{cofib}(f) \cong \Sigma k$. By what we have just proven, both of the cofiber sequences $a \to b \to \Sigma k$ and $k \to * \to \Sigma k$ are fiber sequences, and in particular the right-hand square below is both a pushout and a pullback.

Thus, the outer rectangle factors through the right-hand square and this composite rectangle, which is given as a pushout, is also a pullback. Now by pullback cancelation, the left-hand square is a pullback defining the fiber $k \cong \text{fib}(f)$ of $f : a \to b$.

To see that the fiber sequence $k \to a \to b$ is also a cofiber sequence form the cofiber sequence $k \to a \to c$. Our task is to show the dashed map from the front face of the cube below-left to the back.
Since $\Sigma$ is an equivalence, there exists an arrow $e : z \to w$ in $A$ whose image under $\Sigma$ is isomorphic to the induced map $c \to b$. The cofiber sequences $z \to * \to c$ and $w \to * \to b$ are also fiber sequences, so by pullback cancelation we see that the induced top squares in the prism above-left are pullbacks. From this we see that $e : z \to w$ is a map between two fibers of $k \to a$. Thus $e$ is an isomorphism and the isomorphism $c \cong \Sigma z \cong \Sigma w \cong b$ reveals that the original fiber sequence $k \to a \to b$ is also a cofiber sequence.

4.4.13. REMARK. In fact, stable $\infty$-categories have all finite limits and finite colimits, meaning limits and colimits indexed by simplicial sets with finitely many non-degenerate simplices. More generally, any $\infty$-category with pullbacks and a terminal element admits all finite limits, which can be defined by induction over the dimension of the simplicial set $[74, 4.4.2.4], [108, 6.3.9]$. It follows from this construction and condition (iii) of Theorem 4.4.12 that in a stable $\infty$-category the limit and colimit functors for any finite diagram shape preserve all finite colimits and all finite limits.

A pointed $\infty$-category $A$ admits binary direct sums when there exists a bifunctor

$$A \times A \xrightarrow{\oplus} A$$

that defines both the binary product and coproduct so that the legs of the colimit and limit cones

$$
\begin{array}{ccc}
A & \xrightarrow{\Delta} & A \times A \\
\oplus \downarrow{(t_1, t_2)} & & \downarrow{\delta} \\
A \times A & \xrightarrow{\Delta} & A \\
\end{array}
$$

satisfy the relations

$$
\begin{align*}
\rho_1 \circ t_1 &= \text{id} \\
\rho_1 \circ t_2 &= 0 \\
\rho_2 \circ t_1 &= 0 \\
\rho_2 \circ t_2 &= \text{id}
\end{align*}
$$

where the zero map is defined by Exercise 4.4.ii.

4.4.14. LEMMA. Stable $\infty$-categories admit finite direct sums.

PROOF. We argue that a stable $\infty$-category $A$ has binary direct sums and leave it to Exercise 4.4.iii to extend Exercise 2.3.i to show that $A$ has finite direct sums.

The direct sum bifunctor can be defined by

$$A \times A \xrightarrow{\text{lim}} A \xrightarrow{\rho_1, \rho_2} A \xrightarrow{\text{lim}} A$$
By Exercise 4.3.vii, this construction guarantees that direct sums are products.

To see that the direct sum is also a coproduct, consider the diagram \( A \times A \to A^\oplus \) whose image at an element \((a, b) : 1 \to A \times A\) is depicted below:

\[
\begin{array}{ccc}
* & \overset{\rho_a}{\rightarrow} & a \\
\downarrow \rho_b & & \downarrow \iota_b \rho_a & \downarrow \\
b & \overset{\iota_b}{\rightarrow} & a \oplus b & \overset{\pi_b}{\rightarrow} & b \\
\downarrow \rho_a & & \downarrow \pi_a & \downarrow \\
* & \overset{\iota_a \rho_b}{\rightarrow} & a & \overset{\pi_a \iota_b}{\rightarrow} & * \\
\end{array}
\]

Here the vertical and horizontal composite morphisms are identities, and the right-hand rectangle and lower-rectangle are defined by restricting along a projection functor \( 2 \times 2 \to 2 \) and then using the universal property of the lower-right-hand pullback to factor through that square. By Exercise 2.3.iv, each of these rectangles are themselves pullbacks so by Proposition 4.3.11, we see that the upper-right-hand and lower-left-hand squares so-constructed are pullbacks as well, and thus so too is the upper-left-hand square, by the same reasoning. Since \( A \) is stable, this pullback is a pushout witnessing the fact that the direct sum is also a coproduct.

Note by construction that the composites of the coproduct-inclusions and product-projections are either identities or nullhomotopic. Thus, these biproducts are direct sums.

4.4.15. Digression (the homotopy category of a stable \( \infty \)-category). When an ordinary 1-category has binary direct sums, its hom-sets can be equipped with a canonically-defined commutative monoid structure in such a way that composition defines a bilinear map. For a parallel pair of morphisms \( f, g : x \to y \), their sum is defined to be the composite

\[
f + g := x \xrightarrow{\Delta} x \oplus x \xrightarrow{f \oplus g} y \oplus y \xrightarrow{\nabla} y
\]

By Warning 2.3.3, the zero element and finite direct sums in a stable \( \infty \)-category descend to define a zero element and finite direct sums on its homotopy category. In fact, the homotopy category \( hA \) of a stable \( \infty \)-category \( A \) is additive, meaning that the commutative monoids \( hA(x, y) \) defined by (4.4.16) are in fact abelian groups (that is, each morphism admits an additive inverse) [77, 1.1.2.9].

In fact, Lurie proves in [77, 1.1.2.14] that if \( A \) is a stable \( \infty \)-category, then its homotopy category \( hA \) is triangulated in the sense of Verdier [123]. A triangulated category is an additive category \( hA \) that admits a self-equivalence \( \Sigma : hA \to hA \) together with a class of distinguished triangles

\[
x \xrightarrow{f} y \xrightarrow{g} z \xrightarrow{\Sigma} x
\]

satisfying six axioms. From the vantage point of the 1-category, the class of distinguished triangles is additional structure. In particular, there is no canonical way to define the distinguished triangles for a category of diagrams valued in a triangulated category. Lurie’s insight is that this structure borne by the homotopy category may be captured by a property of the \( \infty \)-category, namely stability. He declares a triple \((f, g, h)\) of morphisms in \( hA \) to be a distinguished triangle if there exist representing arrows

\[
x \xrightarrow{f} y \xrightarrow{g} z \xrightarrow{h} \Sigma x
\]
Let \((f, g, h)\) in \(A\) that assemble into a pushout rectangle of the following form:

\[
\begin{array}{ccc}
x & \xrightarrow{f} & y \\
\downarrow & & \downarrow \\
* & \xrightarrow{r} & Z \\
\downarrow & & \downarrow \\
* & \xrightarrow{h} & \Sigma x
\end{array}
\]

Note at the level of the \(\infty\)-category \(A\) that there is an essentially unique way to extend an arrow \(f: x \to y\) to a distinguished triangle. In particular, the famous “octahedral axiom” is a consequence of the composition and cancelation property for pushout rectangles of Proposition 4.3.11: given a composable pair of morphisms \(f: x \to y\) and \(g: y \to z\) in a stable \(\infty\)-category \(A\), we may form a diagram of pushout squares

\[
\begin{array}{ccc}
x & \xrightarrow{f} & y \\
\downarrow & & \downarrow \\
* & \xrightarrow{r} & \text{cofib}(f) \\
\downarrow & & \downarrow \\
* & \xrightarrow{r} & \text{cofib}(g) \\
\downarrow & & \downarrow \\
* & \xrightarrow{r} & \Sigma x \\
\downarrow & & \downarrow \\
* & \xrightarrow{r} & \Sigma y \\
\downarrow & & \downarrow \\
\Sigma \text{cofib}(f) & \xrightarrow{r} & \Sigma \text{cofib}(f)
\end{array}
\]

which defines a distinguished triangle

\[
\begin{array}{ccc}
\text{cofib}(f) & \xrightarrow{r} & \text{cofib}(g) \\
\downarrow & & \downarrow \\
\Sigma \text{cofib}(f) & \xrightarrow{r} & \Sigma \text{cofib}(f)
\end{array}
\]

compatibly with given distinguished triangles extending \(f, g,\) and \(gf\).

**Exercises.**

4.4.i. **Exercise.** Arguing in the homotopy category, show that if an \(\infty\)-category \(A\)

- admits an initial element \(i\),
- admits a terminal element \(t\), and
- there exists an arrow \(t \to i\)

then \(A\) is a pointed \(\infty\)-category.

4.4.ii. **Exercise.** If \(A\) is a pointed \(\infty\)-category and \(f, g: X \to A\) are functors define a canonical zero map

\[
\begin{array}{ccc}
X & \xrightarrow{f} & A \\
\downarrow \circ & \circ & \downarrow \circ \\
& g & \\
\end{array}
\]

that factors through the constant functor at the zero element.

4.4.iii. **Exercise.** Show that any pointed \(\infty\)-category that admits binary direct sums admits finite direct sums.

4.4.iv. **Exercise.** A functor \(f: A \to B\) between stable \(\infty\)-categories is **exact** if it preserves zero elements as well as fiber and cofiber sequences. Show that exact functors also preserve exact squares.
CHAPTER 5

Fibrations and Yoneda’s Lemma

The aim in this chapter is to describe an infinite-categorical formulation of the functor represented by an element $b: 1 \to B$ of an infinite category $B$, that is described informally by the mapping that sends an element $x$ of $B$ to the internal mapping space $\text{Hom}_B(x, b)$ of Definition 3.4.9. By Proposition 3.4.10, we see that representable functors take values in discrete infinite-categories, which correspond to “spaces” or “infinite-groupoids” in infinite-cosmoi of $(\infty, 1)$-categories.

In contrast with the situation in ordinary 1-category theory, in infinite-category theory it is challenging to explicitly describe the representable functors. The complexity arises in establishing the infinite-functoriality of this mapping, which must encode homotopy coherently functorial actions of arrows in $B$ in each dimension, and this data is too elaborate to easily enumerate even in this fundamental special case.

What turns out to be easier to describe is the infinite-categorical analogue of the “category of elements” associated to the mapping $x \mapsto \text{Hom}_B(x, b)$ together with its associated projection to $B$. In fact, we are quite familiar with this infinite-category already: it is the “right-represented” comma infinite-category $\text{Hom}_B(B, b)$ equipped with its domain-projection functor. Observe that the fiber of $p_0: \text{Hom}_B(B, b) \to B$ over $x: 1 \to B$ recovers the internal mapping space $\text{Hom}_B(x, b)$.

It remains to explain the sense in which $p_0: \text{Hom}_B(B, b) \to B$ expresses the contravariantly functorial of arrows in $B$ on its fibers. This functor enjoys a special property that allows one to lift natural transformations valued in $B$ in an essentially unique way to natural transformations valued in $\text{Hom}_B(B, b)$ with specified codomains. A special case of this lifting defines the precomposition functor $f^*$ associated to an arrow $f: x \to y$ in the homotopy category $hB$:

$$
\begin{array}{ccc}
\text{Hom}_B(y, b) & \xrightarrow{f^*} & \text{Hom}_B(x, b) \\
/ & / & / \\
\downarrow & & \downarrow \\
1 & \xrightarrow{x} & \text{Hom}_B(B, b) \\
\end{array}
$$

Roughly speaking, an isofibration $p: E \to B$ defines a cartesian fibration just when the arrows of $B$ act contravariantly functorially on the fibers and a cocartesian fibration when the arrows of $B$ act covariantly functorially on the fibers. The functor $p_0: \text{Hom}_B(B, b) \to B$ is an example of a discrete cartesian fibration, whose fibers are discrete infinite-categories. When $b: X \to B$ is a generalized element, the domain-projection functor $p_0: \text{Hom}_B(B, b) \to B$ remains a cartesian fibration, but loses this discreteness property.
One of the properties that characterizes cartesian fibrations is an axiom that says that for any 2-cell with codomain $B$ and specified lift of its target 1-cell, there is a lifted 2-cell with codomain $E$ with that 1-cell as its target. In particular, this lifting property can be applied in the case where the 2-cell in question is a whiskered composite of an arrow in the homotopy category of $B$ as below-left and the lift of the source 1-cell is the canonical inclusion of the fiber over its domain:

\[
\begin{array}{c}
E_b \\
\downarrow b \\
1
\end{array}
\quad \Rightarrow 
\begin{array}{c}
E \\
p \\
1
\end{array}
\quad = 
\begin{array}{c}
E_b \\
\downarrow b \\
1
\end{array}
\quad \Rightarrow 
\begin{array}{c}
E_a \\
\downarrow a \\
B
\end{array}
\quad \Rightarrow 
\begin{array}{c}
E \\
p \\
1
\end{array}
\]

In this case the codomain $\beta_*(\ell_a)$ of the lifted cell $\chi_\beta$ displayed above right lies strictly above the codomain of the original 2-cell, and thus factors through the pullback defining its fiber. This defines a functor $\beta^*: E^b \to E^a$, the “action” of the arrow $\beta$ on the fibers of $p$. This action is not strict but rather pseudofunctorial in a sense explored in Exercise 5.2.iii. The pseudofunctoriality of these action maps arises from a universal property required of the specified lifted 2-cells, namely that they are cartesian in a sense we define in §5.1.

Cartesian fibrations are introduced in §5.2, where the first examples are also established. The main theorem in this section characterizes cartesian fibrations in terms of the presence of adjoints to certain canonically-defined functors. The natural maps between cartesian fibrations are commutative squares called cartesian functors, preserving the cartesian natural transformations. In §5.3, we see that these can similarly be characterized relative to the adjunctions constructed in §5.2.

In §5.4 we study the dual cocartesian fibrations, for which there exist lifts of natural transformations with a specified domain functor. By a dual of the construction displayed in (5.0.1), when $p: E \to B$ is a cocartesian fibration an arrow $\beta: a \to b$ in $hB$ defines a functor $\beta_*: E_a \to E_b$. An isofibration $p$ that is simultaneously a cartesian fibration and a cocartesian fibration is called a bifibration.¹ In this case Proposition 5.4.7 proves that the induced functors $\beta_* \dashv \beta^*$ are adjoints.

In §5.5, we show that when $p: E \to B$ is a cartesian fibration in an $\infty$-cosmos the induced functor $p_*: \text{Fun}(X, E) \to \text{Fun}(X, B)$ defines a cartesian fibration of quasi-categories. The converse also holds, under the additional condition that restriction along any $f: Y \to X$ defines a cartesian functor.

The special classes of discrete cartesian fibrations and discrete cocartesian fibrations are studied in §5.6. This chapter concludes in §5.7 with a version of the Yoneda lemma for the discrete cartesian fibration $p_0: \text{Hom}_B(B, b) \to B$ that is represented by the element $b: 1 \to B$. Its formulation was inspired by a paper of Street “Fibrations and Yoneda’s lemma in a 2-category” [113],² the debt to which we recognize in the title of this section.

### 5.1. Cartesian Arrows

To remind the reader of the interpretation of the data in the homotopy 2-category of an $\infty$-cosmos, we refer to 1- and 2-cells as “functors” and “natural transformations.” Before defining the notion of

---

¹In [74, §2.4.7], Lurie uses the term “bifibration” to refer to a different class of functors: the modules of Chapter 7.

²The closest analogue to Street’s Yoneda Lemma [113, 16] appears as Theorem 7.4.9.
cartesian fibration we describe the weak universal property enjoyed by a certain class of “upstairs” natural transformations.

5.1.1. Definition (\(p\)-cartesian transformation). Let \(p: E \to B\) be an isofibration. A natural transformation \(X \xrightarrow{\psi} E\) with codomain \(E\) is \(p\)-cartesian if the “composition with \(\psi\)” and “composition with \(p\psi\)” functors defined by Corollary 3.5.11 and the “application of \(p\)” functors defined by Proposition 3.4.5 define a weak pullback square\(^3\)

\[
\begin{array}{ccc}
\text{Hom}_E(E, e') & \xrightarrow{\psi_*} & \text{Hom}_E(E, e) \\
\downarrow & & \downarrow \\
\text{Hom}_B(B, pe') & \xrightarrow{p\psi_*} & \text{Hom}_B(B, pe)
\end{array}
\] (5.1.2)

meaning that the induced map

\[
\text{Hom}_E(E, e') \Rightarrow \text{Hom}_B(B, pe') \times_{\text{Hom}_B(B, pe)} \text{Hom}_E(E, e)
\]

is an equivalence.

Pullback squares are sometimes called “cartesian squares” explaining the terminology. The defining universal property of \(p\)-cartesian transformations can be re-characterized as follows:

5.1.3. Lemma (\(p\)-cartesian transformations). Let \(p: E \to B\) be an isofibration. A natural transformation \(X \xrightarrow{\psi} E\) with codomain \(E\) is \(p\)-cartesian if and only if the induced map

\[
\begin{array}{ccc}
\text{Hom}_E(E, e') & \xrightarrow{\psi_*} & \text{Hom}_E(E, e) \\
\downarrow & & \downarrow \\
\text{Hom}_B(p, pe') & \xrightarrow{p\psi_*} & \text{Hom}_B(p, pe)
\end{array}
\] \((5.1.4)\)

defines an equivalence over \(X \times E\).

\(^3\)Recall from Proposition 3.4.7 that the functors \("\psi_*"\) and \("p\psi_*"\) are well-defined up to fibered isomorphism. Given arbitrary choices of functors representing these fibered isomorphism classes, the weak pullback square will commute up to isomorphism. The fibered isomorphism between two representatives of the functor \("p\psi_*"\) can be pulled back along \(X \times p: X \times E \to X \times B\) to define a fibered isomorphism over \(X \times E\) (see the diagram in the proof of Lemma 5.1.3) and now the weak pullback square commutes up to fibered isomorphism over \(X \times E\). This isomorphism can be lifted along the isofibration \(\text{Hom}_p(id, id): \text{Hom}_p(E, e) \to \text{Hom}_p(p, pe)\), at the cost of replacing \("\psi_*"\) by another functor in the same fibered isomorphism class over \(X \times E\). Thus, for convenience, we are free to make choices of representing functors so that this square commutes strictly. Exercise 5.1.i verifies that the notion of \(p\)-cartesian transformation is well-defined.
Proof. The lower-horizontal map in the square (5.1.2) can be pulled back along the isofibration $X \times p : X \times E \to X \times B$ to define the square over $X \times E$ displayed at the top of the rectangle:

Here the functor $\sim p\psi_\star : \text{Hom}_B(p, pe') \to \text{Hom}_B(p, pe)$ is a strict pullback of the corresponding functor $\sim p\psi_\star : \text{Hom}_B(B, pe') \to \text{Hom}_B(B, pe)$ so the square (5.1.2) is a weak pullback if and only if the square displayed on the top of this diagram is a weak pullback. □

5.1.5. COROLLARY (p-cartesian transformations as terminal elements). A $p$-cartesian transformation $X \xrightarrow{\psi} E$ defines a terminal element over $X$

$$X \xrightarrow{\sim p\psi_\star} \text{Hom}_B(p, pe') \times_{\text{Hom}_B(p, pe)} \text{Hom}_E(E, e)$$

Proof. By Lemma 3.5.9 and Example 3.6.10, $\sim \text{id}_{e'} : X \to \text{Hom}_E(E, e')$ defines a terminal element over $X$ whose image under the equivalence (5.1.4) is the terminal element of the statement. □

Corollary 5.1.5 provides a way to understand the universal property of $p$-cartesian transformations. For economy of language, suppose $X = 1$ so that $\psi : e' \Rightarrow e$ is an arrow in the homotopy category of $E$. Then $\psi$ defines a $p$-cartesian transformation just when the pair $\langle \sim \text{id}_{pe'}, \sim \psi \rangle : 1 \to \text{Hom}_B(p, pe') \times_{\text{Hom}_B(p, pe)} \text{Hom}_E(E, e)$ defines a terminal element. Informally, $\langle \sim \text{id}_{pe'}, \sim \psi \rangle$ is terminal among pairs of arrows $\gamma : pe'' \Rightarrow pe'$ and $\tau : e'' \Rightarrow e$ so that $p\tau = p\psi \cdot \gamma$.

The next several lemmas describe various stability properties for the class of $p$-cartesian transformations defined relative to a fixed isofibration $p : E \to B$.

5.1.6. LEMMA (stability under restriction). If $X \xrightarrow{\psi} E$ is a $p$-cartesian transformation then so is its restriction $Y \xrightarrow{f} X \xrightarrow{\psi} E$ along any functor $f$. 

148
Proof. By Lemma 5.1.3, if \( \psi \) is \( p \)-cartesian we have an equivalence

\[
\begin{array}{ccc}
\text{Hom}_E(E, e') & \xrightarrow{\psi^*} & \text{Hom}_E(E, e) \\
\downarrow \quad \downarrow & & \quad \downarrow \quad \downarrow \\
\text{Hom}_B(p, pe') & \xrightarrow{\mu^*} & \text{Hom}_B(p, pe)
\end{array}
\]

over \( X \times E \). By Proposition 3.3.3, this pulls back along any functor \( f \times E : Y \times E \to X \times E \) to define an equivalence witnessing the fact that \( \psi f \) is also a \( p \)-cartesian transformation. \( \square \)

The class of \( p \)-cartesian transformations is closed under composition and left cancelation:

5.1.7. Lemma. Let \( p : E \to B \) be an isofibration and consider a composable pair of natural transformations

\[
X \xrightarrow{\psi} E \quad \text{and} \quad X \xrightarrow{\psi'} E
\]

with codomain \( E \).

(i) If \( \psi \) and \( \psi' \) are \( p \)-cartesian, then so is \( \psi \cdot \psi' \).

(ii) If \( \psi \) and \( \psi \cdot \psi' \) are \( p \)-cartesian, then so is \( \psi' \).

Proof. For both statements, we are lead to consider the diagram

\[
\begin{array}{ccc}
\text{Hom}_E(E, e'') & \xrightarrow{\psi''^*} & \text{Hom}_E(E, e') \\
\downarrow \quad \downarrow & & \quad \downarrow \quad \downarrow \\
\text{Hom}_B(B, pe'') & \xrightarrow{\mu''^*} & \text{Hom}_B(B, pe')
\end{array}
\]

where the right-hand square is assumed to be a weak pullback square. By Proposition 3.3.3, the weak equivalence \( \text{Hom}_E(E, e') \cong \text{Hom}_B(B, pe') \times_{\text{Hom}_B(B, pe)} \text{Hom}_E(E, e) \) pulls back to define the displayed dotted weak equivalence from the codomain of the map that detects whether \( \psi' \) is \( p \)-cartesian to the codomain of the map that detects whether \( \psi \cdot \psi' \) is \( p \)-cartesian:

\[
\begin{array}{ccc}
\text{Hom}_E(E, e'') & \xrightarrow{\psi''^*} & \text{Hom}_E(E, e') \\
\downarrow \quad \downarrow & & \quad \downarrow \quad \downarrow \\
\text{Hom}_B(B, pe'') & \xrightarrow{\mu''^*} & \text{Hom}_B(B, pe')
\end{array}
\]

By the 2-of-3 property for equivalences of Lemma 1.2.20, either of these conditions implies the other, proving (i) and (ii). \( \square \)

The universal property of \( p \)-cartesian transformations implies that any two \( p \)-cartesian lifts of a common 2-cell whose codomain 1-cells agree are fibered isomorphic:
5.1.8. Lemma (uniqueness of cartesian lifts). If \( X \xrightarrow{\psi} E \) and \( X \xrightarrow{\psi'} E \) are \( p \)-cartesian lifts of a common 2-cell \( \beta : b \Rightarrow pe \), then there exists an invertible 2-cell \( X \xrightarrow{\zeta} E \) so that \( \psi' = \psi \cdot \zeta \) and \( p\zeta = \text{id}_b \).

Proof. By Definition 5.1.1 and Lemma 5.1.3, by hypothesis \( \text{Hom}_E(E, e') \) and \( \text{Hom}_E(E, e'') \) both define weak pullbacks of \( \beta^* : \text{Hom}_B(p, b) \to \text{Hom}_B(p, pe) \) along \( \text{Hom}_p(\text{id}, \text{id}) : \text{Hom}_E(E, e) \to \text{Hom}_B(p, pe) \). Since the weak pullback squares both lie over \( X \times E \), the postulated equivalences

\[
\begin{array}{ccc}
\text{Hom}_E(E, e') & \sim & \text{Hom}_B(p, b) \\
\times & \text{Hom}_B(id, id) & \text{Hom}_E(E, e) \\
\downarrow & \downarrow & \downarrow \\
X \times E & \sim & \text{Hom}_E(E, e'')
\end{array}
\]

both lie over \( X \times E \). By Proposition 3.6.4, these equivalences can then be inverted over \( X \times E \), defining a composite fibered equivalence \( \text{Hom}_E(E, e'') \approx_{X \times E} \text{Hom}_E(E, e') \) as displayed

By Corollary 3.5.11, this equivalence represents a natural transformation \( X \xrightarrow{\psi} E \). By Exercise 3.6.ii, \( \zeta \) is necessarily an isomorphism. Since there is a fibered isomorphism \( \psi^* \approx \psi^* \cdot \zeta^* \), by Corollary 3.5.11, we must have \( \psi' = \psi \cdot \zeta \). Similarly, from the fibered isomorphism \( \text{Hom}_p(\text{id}, \text{id}) \approx \text{Hom}_p(\text{id}, \text{id}) \cdot \zeta^* \) it follows that \( p\zeta = \text{id} \).

The isomorphism stability of the \( p \)-cartesian transformations expressed by the following suite of observations follows easily from Proposition 3.3.2 and the results just proven:

5.1.9. Lemma. Let \( p : E \Rightarrow B \) be an isofibration.

(i) Isomorphisms with codomain \( E \) define \( p \)-cartesian transformations.
(ii) Any \( p \)-cartesian lift of a natural isomorphism is a natural isomorphism.
(iii) The class of \( p \)-cartesian transformations is closed under pre- and post-composition with natural isomorphisms.

Proof. Exercise 5.1.ii.

Combining these results, we obtain a useful conservativity property:
5.1.10. **Lemma** (cartesian conservativity). If \( X \xrightarrow{\psi} E \), \( X \xrightarrow{\psi'} E \), and \( X \xrightarrow{\psi''} E \) are natural transformations so that \( \psi \) and \( \psi' \) are p-cartesian, \( \psi' = \psi \cdot \zeta \), and \( p\zeta \) is invertible, then \( \zeta \) is invertible.

**Proof.** By Lemma 5.1.7 and Lemma 5.1.9, \( \zeta \) is a p-cartesian lift of a natural isomorphism and hence it must be invertible.

The universal property that characterizes the p-cartesian transformations in Definition 5.1.1 gives rise to induction and conservativity operations at the level of the homotopy 2-category, analogously to those operations considered in Chapter 3.

5.1.11. **Proposition** (the weak universal property of p-cartesian transformations). Let \( p : E \twoheadrightarrow B \) be an isofibration. A p-cartesian natural transformation \( X \xrightarrow{\psi} E \) has a weak universal property in the homotopy 2-category given by two operations:

(i) **induction:** Given any natural transformations \( X \xrightarrow{\psi} E \) and \( X \xrightarrow{\psi'} B \) so that \( p\tau = p\psi \cdot \gamma \),

there exists a lift \( X \xrightarrow{\psi''} E \) of \( \gamma \) so that \( \tau = \psi \cdot \bar{\gamma} \).

(ii) **conservativity:** Any fibered endomorphism of \( \psi \) is invertible: if \( X \xrightarrow{\psi} E \) is any natural transformation so that \( \psi \cdot \zeta = \psi \) and \( p\zeta = \text{id}_{pe'} \) then \( \zeta \) is invertible.

**Proof.** The conservativity property is a special case of the conservativity result observed in Lemma 5.1.10 so it remains to prove (i).
Given natural transformations \( \tau : e'' \Rightarrow e \) and \( \gamma : pe'' \Rightarrow pe' \) as in (i), by Corollary 3.5.11 we may form the solid-arrow diagram

\[
\begin{array}{ccc}
\text{Hom}_E(E, e'') & \xrightarrow{\tau_*} & \text{Hom}_E(E, e) \\
\downarrow \text{Hom}_B(p, id) & & \downarrow \text{Hom}_B(p, id) \\
\text{Hom}_B(B, pe'') & \xrightarrow{\gamma_*} & \text{Hom}_B(B, pe) \\
\end{array}
\]

Since \( p\tau = \psi \cdot \gamma \), this solid-arrow diagram commutes up to isomorphism over \( X \times B \), but since \( \text{Hom}_B(p, \text{id}) \) is an isofibration this isomorphism can be absorbed into the functor \( \tau_* \) without changing its fibered isomorphism class over \( X \times E \). The outer commutative pentagon then induces a map, not displayed, to the pullback of \( \psi_* \) along \( \text{Hom}_B(p, \text{id}) \). Since \( \psi \) is \( p \)-cartesian, \( \text{Hom}_E(E, e') \) is equivalent over \( X \times E \) to this pullback and by inverting the equivalence, we obtain the displayed dashed map commuting up to fibered isomorphism with the legs of the cone that induces it. As in the proof of Lemma 5.1.8, the top fibered isomorphism tells us that \( \tau = \psi \cdot \gamma \), while the left-hand fibered isomorphism tells us that \( \gamma = p\bar{\gamma} \).

The universal properties enumerated by Proposition 5.1.11 are considerably weaker than that expressed by Definition 5.1.1. Nevertheless, rather surprisingly, conditions (i) and (ii), together with the restriction stability properties explored in Exercise 5.1.iii, suffice to characterize the class of \( p \)-cartesian transformations—under the condition that \( p \) is a cartesian fibration, a concept that will be introduced in the next section; see Proposition 5.2.18. This enables one to develop the theory of cartesian fibrations entirely from the perspective of the homotopy 2-category. Since, however, \( p \)-cartesian transformations are of interest in their own right even in cases where \( p \) is not itself a cartesian fibration, we decline to explore this avenue here and instead refer the reader to [106].

**Exercises.**

5.1.i. Exercise. The horizontal functors appearing in (5.1.2) are well-defined up to fibered natural isomorphism. Argue that the notion of \( p \)-cartesian transformation introduced in Definition 5.1.1 is well-defined by verifying that if map induced to the pullback is an equivalence for one choice of representing functors than it is an equivalence for any choice of representing functors.

5.1.ii. Exercise. Prove Lemma 5.1.9.

5.1.iii. Exercise. Generalize the induction operation of Proposition 5.1.11(i) to induce lifts of factorizations through a restriction of a \( p \)-cartesian natural transformation along an arbitrary functor. The conservativity property can be generalized similarly.

**5.2. Cartesian Fibrations**

We now introduce the class of cartesian fibrations, which generalize the Grothendieck fibrations between ordinary 1-categories. This notion was first extended to quasi-categories by Joyal [60] and Lurie [74] and to complete Segal spaces by Boavida de Brito [34] and Rasekh [92]. The class of functors between \((\infty, 1)\)-categories has also been studied “model-independently” by Mazel-Gee [84] and Ayala-Francis [3].
5.2.1. **Definition** (cartesian fibration). An isofibration \( p : E \to B \) is a **cartesian fibration** if any natural transformation \( \beta : b \Rightarrow pe \) as below-left admits a \( p \)-cartesian lift \( \chi_\beta : \beta^* e \Rightarrow e \) as below-right:

\[
\begin{array}{ccc}
X & \xrightarrow{e} & E \\
\downarrow \beta & & \downarrow p \\
B & \xrightarrow{\beta e} & B
\end{array} =
\begin{array}{ccc}
X & \xrightarrow{\beta^* e} & E \\
\downarrow \beta & & \downarrow p \\
B & \xrightarrow{\beta e} & B
\end{array}
\]

5.2.2. **Remark.** A guiding moral principle of \( \infty \)-category theory is that all \( \infty \)-categorical notions should be equivalence-invariant. Note, however, that if \( E \) and \( B \) are replaced by equivalent \( \infty \)-categories \( E' \) and \( B' \) the equivalent functor \( p' : E \to B \) is not necessarily an isofibration. By Lemma 1.2.16, however, it is equivalent to an isofibration \( p'' \) over \( B' \), however, so if we were forced to, we could declare \( p' \) to be a cartesian fibration just when \( p'' \) is an isofibration in the sense of Definition 5.2.1. By Corollary 5.3.1, this definition is now equivalence-invariant. For technical reasons, such as Proposition 6.4.13, we prefer to leave Definition 5.2.1 as it is.

Certain stability properties of the class of cartesian fibrations can be proven directly from this definition.

5.2.3. **Lemma** (composites of cartesian fibrations). If \( p : E \to B \) and \( q : B \to A \) are cartesian fibrations, then so is \( qp : E \to A \). Moreover, a natural transformation \( \chi : e' \Rightarrow e \) is \( qp \)-cartesian if and only if \( \chi \) is \( p \)-cartesian and \( p\chi \) is \( q \)-cartesian.

**Proof.** The first claim follows immediately from the second, for the required lifts can be constructed by first taking a \( q \)-cartesian lift \( \chi_\beta \) and then taking a \( p \)-cartesian lift \( \chi_{\beta e} \) of this lifted cell.

To prove the second claim, first consider a natural transformation \( \psi : e' \Rightarrow e \) that is \( p \)-cartesian and so that \( p\psi \) is \( q \)-cartesian. By Definition 5.1.1, these properties are expressed by the dashed weak

\[\text{lift of } \beta : b \Rightarrow pe \text{ asserts that } p\chi_\beta = \beta \text{ and hence } p\beta e = b.\]
equivalences, the latter of which pulls back to define the dotted weak equivalence:

\[
\begin{align*}
\text{Hom}_E(E, e') &\xrightarrow{\psi_*} \text{Hom}_E(E, e) \\
\text{Hom}_B(B, pe') &\xrightarrow{p\psi_*} \text{Hom}_B(B, pe) \\
\text{Hom}_A(A, qpe') &\xrightarrow{qp\psi_*} \text{Hom}_A(A, qpe)
\end{align*}
\]

Since equivalences compose, this tells us that the map \(\text{Hom}_E(E, e'') \to \text{Hom}_A(A, qpe') \times_{\text{Hom}_A(A, qpe)} \text{Hom}_E(E, e)\) is an equivalence, and thus \(\psi\) is \(qp\)-cartesian.

Conversely, if \(\psi\) is \(qp\)-cartesian, then Lemma 5.1.8 implies it is isomorphic to all other \(qp\)-cartesian lifts of \(qp\psi\). The construction given above produces a \(qp\)-cartesian lift of any 2-cell that is \(p\)-cartesian and whose image under \(p\) is \(q\)-cartesian. By the isomorphism stability of \(p\)- and \(q\)-cartesian transformations of Lemma 5.1.9, \(\psi\) must also have these properties.

\[\square\]

5.2.4. PROPOSITION (pullback stability). In any pullback square

\[
\begin{array}{c}
F \\
\downarrow^h \\
E \\
\downarrow^p \\
A \\
\downarrow^k \\
B
\end{array}
\]

if \(p\) is a cartesian fibration then \(q\) is a cartesian fibration. Moreover, a natural transformation \(\psi\) with codomain \(F\) is \(q\)-cartesian if and only if \(h\psi\) is \(p\)-cartesian.

PROOF. Consider a natural transformation \(\alpha: a \Rightarrow qf\) as below-left. Since \(p\) is a cartesian fibration the natural transformation \(k\alpha: ka \Rightarrow kqf = phf\) has a \(p\)-cartesian lift displayed below-center:

The commutative square \(pe = ka\) induces a functor \(d: X \to F\) that gives a factorization of the domain of \(\tau\) through \(h\), as displayed above-right. By construction \(p\tau = k\alpha\), so by Proposition 3.3.1 the pair induces a 2-cell \(\sigma: d \Rightarrow f\) so that \(q\sigma = \alpha\) and \(h\sigma = \tau\). In particular, \(\sigma\) defines a lift of \(\alpha\) with codomain \(f\), and \(h\sigma\) is a \(p\)-cartesian transformation. So if we prove the second part of the statement—that a
natural transformation \( \psi : f' \Rightarrow f \) with codomain \( F \) is \( q \)-cartesian if and only if \( h\psi \) is \( p \)-cartesian—then we will have shown that \( q \) is itself a cartesian fibration with cartesian cells created by the pullback.

To that end consider the cube

\[
\begin{array}{cccc}
\text{Hom}_F(F, f') & \xrightarrow{\psi_*} & \text{Hom}_F(F, f) \\
\downarrow & & \downarrow \\
\text{Hom}_E(E, hf') & \xrightarrow{h\psi_*} & \text{Hom}_E(E, hf) \\
\downarrow & & \downarrow \\
\text{Hom}_A(A, qf') & \xrightarrow{q\psi_*} & \text{Hom}_A(A, qf) \\
\downarrow & & \downarrow \\
\text{Hom}_B(B, phf') & \xrightarrow{ph\psi_*} & \text{Hom}_B(B, phf)
\end{array}
\]

By the hypercube pullback lemma, the left and right faces are strict pullback squares. Hence the map from \( \text{Hom}_E(E, hf') \) to the pullback in the front face pulls back to the map from \( \text{Hom}_F(F, f') \) to the pullback in the back face. Thus, by Proposition 3.3.3 if \( h\psi \) is \( p \)-cartesian then \( \psi \) is \( q \)-cartesian. This completes the proof that \( q \) is a cartesian fibration.

Now if \( \psi \) is \( q \)-cartesian then by Lemma 5.1.8, \( \psi \) is isomorphic to the lift \( q \)-cartesian lift \( \sigma \) of \( q\psi \) constructed in first part of this proof. Thus \( h\psi \) is isomorphic to \( h\sigma = \tau \), which is \( p \)-cartesian, so by Lemma 5.1.9, \( h\psi \) must be \( p \)-cartesian as well. \( \square \)

In fact, it suffices in Definition 5.2.1 to assume only that the generic transformation whose codomain factors through \( p \) admits a \( p \)-cartesian lift:

5.2.5. **Lemma.** An isofibration \( p : E \to B \) is a cartesian fibration if and only if the right comma cone over \( p \) displayed below-left admits a \( p \)-cartesian lift \( \chi \) as displayed below-right:

\[
\begin{array}{cccc}
\text{Hom}_B(B, p) & \xrightarrow{p_1} & E \\
\downarrow p_0 & & \downarrow p \\
B & & B
\end{array}
\]

\[
\begin{array}{cccc}
\text{Hom}_B(B, p) & \xrightarrow{p_1} & E \\
\downarrow r & & \downarrow p \\
B & & B
\end{array}
\]

\( (5.2.6) \)

**Proof.** If \( p : E \to B \) is cartesian, then the right comma cone \( \phi \) admits a \( p \)-cartesian lift \( \chi : r \Rightarrow p_1 \). For the converse, suppose we are given the generic \( p \)-cartesian transformation \( \chi : r \Rightarrow p_1 \) of the statement and consider a 2-cell \( \beta : b \Rightarrow pe \) as below-left.

\[
\begin{array}{cccc}
X & \xrightarrow{e} & E \\
\downarrow b & & \downarrow p \\
B & & B
\end{array}
\]

\[
\begin{array}{cccc}
X & \xleftarrow{\beta} & \text{Hom}_B(B, p) \\
\downarrow b & & \downarrow p_0 \\
B & & B
\end{array}
\]

\[
\begin{array}{cccc}
X & \xleftarrow{\beta} & \text{Hom}_B(B, p) \\
\downarrow b & & \downarrow p_0 \\
B & & B
\end{array}
\]

\[
\begin{array}{cccc}
X & \xrightarrow{e} & E \\
\downarrow b & & \downarrow p \\
B & & B
\end{array}
\]

\[\text{The hypercube pullback lemma says that the limit of a diagram of shape } a \times a \text{ can be computed by first forming the pullbacks in the left factor and then forming the pullback of the resulting cospan, or by first forming the pullbacks in the right factor and then forming the pullback of the resulting cospan.} \]
By 1-cell induction $\beta = \phi \beta^n$ for some functor $\beta^n: X \to \text{Hom}_B(B, p)$ as above-center. By substituting the equation (5.2.6) as above-right, we see that $\chi^{\beta^n}$ is a lift of $\beta$ whose codomain is $p_1 \beta^n = e$, as required. By Lemma 5.1.6, $\chi^{\beta^n}$ defines the required $p$-cartesian lift $\chi_\beta$ of $\beta: b \Rightarrow pe$.

5.2.7. REMARK (the universal property of the generic $p$-cartesian transformation). When $p$ is a cartesian fibration, we refer to the cartesian transformation $\chi: r \Rightarrow p_1$ of (5.2.6) as the generic $p$-cartesian transformation. Its universal property is expressed by the weak pullback square

$$
\begin{array}{c}
\text{Hom}_E(E, r) \\
\downarrow \text{Hom}_E(E, p_1) \\
\downarrow \\
\text{Hom}_B(B, p_0) \\
\downarrow \text{Hom}_B(B, pp_1)
\end{array}
$$

whose underlying cospan is built from data canonically associated to the isofibration $p: E \to B$, which we now describe.

The weak pullback of the underlying cospan can be computed by the pullback-hypercube:

![Hypercube Diagram](image)

where all of the maps are isofibrations, defined either by $p: E \to B$ or by restricting along one of the six functors:

$$
\begin{array}{c}
1 \\
\downarrow \ell \\
\downarrow \\
\downarrow \\
\delta
\end{array}
$$

Here $\delta: \Delta \hookrightarrow \Delta^3$ has image given by the cospan $0 \to 2 \leftarrow 1$ in $\Delta^3$ and $\ell$ is the unique functor making the right-hand triangle commute. The solid-arrow squares are each pullbacks, defining the comma $\infty$-categories of the original cospan, in the case of the lower-left-hand square up to equivalence and in the other two cases strictly. The dotted squares are trivially pullbacks as well. Consequently, by the hypercube pullback lemma, the dashed square is a weak pullback, which tells us that the weak pullback that expresses the universal property of the generic $p$-cartesian transformation is equivalent to $E^2 \times_{B^2} B^3$.  

156
5.2.9. Remark (action of arrows on the fibers of a cartesian fibration). The action \((5.0.1)\) of an arrow in the base of a cartesian fibration \(p: E \to B\) on the fibers can be described as follows. Consider a natural transformation \(\beta\) with codomain \(B\) and form the fibers of \(p\) over its domain and codomain functors

\[
\begin{array}{c}
X @>{\beta}>> B \\
\downarrow_{b} & \searrow_{p} \\
X @>{\beta}>> B
\end{array}
\]

The action \((5.0.1)\) of an arrow \(a\) in the base of a cartesian fibration \(p: E \to B\) on the fibers can be described as follows. Consider a natural transformation \(\beta\) with codomain \(B\) and form the fibers of \(p\) over its domain and codomain functors

\[
\begin{array}{c}
E_a @>>> E @<<< E_b \\
p_a \downarrow & \searrow p & \downarrow p_b \\
X @>{a}>> B @<<< X
\end{array}
\]

The pullback square defining the fiber \(E_b\) factors as below-left

\[
\begin{array}{c}
E_b @>>> \text{Hom}_B(B, p) @>>> E @<<< E_b \\
p_b \downarrow & \searrow q & \downarrow p & \downarrow p_b \\
X @>>{\beta}>> B^2 @<<< X
\end{array}
\]

and thus the rectangle displayed above-right defines a cone over the pullback defining \(E_a\), inducing a map \(\beta^*: E_b \to E_a\). The top-horizontal functor in this rectangle recovers the domain-component \(\beta^*(\ell_b)\) of the \(p\)-cartesian lift of \(\beta\) with codomain \(\ell_b\). This recovers the definition of \(\beta^*: E_b \to E_a\) given at the start of this chapter.

Lemma 5.2.5 extends to give an internal characterization of cartesian fibrations inspired by a similar result Street [113, 116, 117], which in turn was inspired by previous work of Gray [46] on what he calls a “Chevalley criterion”; see also [127]. As we shall see, the universal property of a cartesian fibration \(p: E \to B\) can be encoded by the data of a suitable right adjoint to the functor \(\eta_{\text{id}_p}\): \(E \to \text{Hom}_B(B, p)\) induced from the identity 2-cell or to the functor \(\eta_{p\kappa}\): \(E^2 \to \text{Hom}_B(B, p)\) induced from \(p\) applied to the generic arrow \(\kappa\) for \(E\).

5.2.10. Theorem (an internal characterization of cartesian fibrations). For an isofibration \(p: E \to B\) the following are equivalent:

(i) \(p: E \to B\) defines a cartesian fibration.

(ii) The functor \(\eta_{\text{id}_p}: E \to \text{Hom}_B(B, p)\) admits a right adjoint over \(B\):

\[
\begin{array}{ccc}
E & \overset{\text{id}_p}{\longrightarrow} & \text{Hom}_B(B, p) \\
p \downarrow & & \downarrow p_0 \\
B & & \\
\end{array}
\]

(iii) The functor \(\eta_{p\kappa}: E^2 \to \text{Hom}_B(B, p)\) admits a right adjoint right inverse:

\[
\begin{array}{ccc}
E^2 & \overset{\text{id}_p}{\longrightarrow} & \text{Hom}_B(B, p) \\
p \downarrow & & \downarrow p_0 \\
B & & \\
\end{array}
\]

\[\text{---} \text{Gray attributes [46, 3.11]---the special case of the equivalence of (i)$\Leftrightarrow$(ii) of Theorem 5.2.10 in the \(\infty\)-cosmos \(\text{Cat}\)---to unpublished notes from a seminar given by Chevalley at Berkeley in 1962.} \]
When these conditions hold, then for a natural transformation \( X \xrightarrow{\psi} E \) the following are equivalent:

(iv) \( \psi \) is \( p \)-cartesian.

(v) \( \psi \) factors through a restriction of the generic \( p \)-cartesian transformation \( p_1 \epsilon \), where \( \epsilon \) is the counit of the adjunction \( \epsilon \Gamma_p \dashv r \), via a natural isomorphism \( \gamma \) so that \( p \gamma = \text{id} \):

\[
X \xrightarrow{\psi} E = X \xrightarrow{p \psi} \text{Hom}_B(B, p) \xrightarrow{\epsilon} \text{Hom}_B(B, p) \xrightarrow{p_1} E
\]

(vi) The component

\[
X \xrightarrow{\psi} E^2 \xrightarrow{r \epsilon \gamma} E^2
\]

of the unit for \( r \chi \circ \psi \) is invertible, i.e., \( \psi \gamma \) is in the essential image of the functor \( \chi \).

As the proof reveals, the right adjoint of (ii) is the domain-component of the generic \( p \)-cartesian lift \( \chi \) of (5.2.6); that \( p \)-cartesian transformation is then recovered as \( p_1 \epsilon \), where \( \epsilon \) is the counit of the fibered adjunction \( r \dashv \Gamma_p \). Via Lemmas 5.1.9 and 5.1.10, this explains the statement of (v). By 1-cell induction, the generic cartesian lift \( \chi \) can be represented by a functor \( \chi^* \): \( \text{Hom}_B(B, p) \to E^2 \) and this defines the right adjoint of (iii) and explains the statement of (vi).

Before proving Theorem 5.2.10 we make two further remarks on these postulated left adjoints.

5.2.11. Remark. By Lemma 3.5.9, the functor \( \Gamma_p \): \( E \to \text{Hom}_B(B, p) \) is itself a right adjoint over \( B \) to the codomain-projection functor.

Since the counit of the adjunction \( p_1 \dashv \Gamma_p \) is an isomorphism, it follows formally that the unit of the adjunction \( \Gamma_p \dashv r \) must also be an isomorphism, whenever the adjunction postulated in (ii) exists; see Lemma B.3.9. Thus \( r \) defines a right adjoint left inverse to \( \Gamma_p \) over \( B \).
5.2.12. Remark. In the case where the \( \infty \)-categories \( E^2 \) and \( \text{Hom}_B(B,p) \) are defined by the strict simplicial limits of Definitions 3.2.1 and 3.4.1, the 1-cell \( r p \kappa \) induced by the pasting diagram

\[
\begin{array}{ccc}
E^2 & \xrightarrow{p_1} & E \\
\downarrow{p} & & \downarrow{p} \\
B & & B
\end{array}
\]

\[
\begin{array}{ccc}
E & \xrightarrow{\text{Hom}_B(B,p)} & E^2 \\
\downarrow{p_1} & & \downarrow{p_0} \\
B & \xleftarrow{\phi} & B
\end{array}
\]

can be modeled by an isofibration:

\[
\begin{array}{ccc}
E^2 & \xrightarrow{\kappa \phi} & E^2 \\
\downarrow{p_1} & & \downarrow{p_0} \\
\text{Hom}_B(B,p) & \xleftarrow{\psi} & B^2 \\
\downarrow{p_1} & & \downarrow{p_1} \\
E & \xrightarrow{p} & B
\end{array}
\]

namely the Leibniz cotensor of the codomain inclusion \( 1 : 1 \to 2 \) and the isofibration \( p : E \to B \). Now Lemma 3.6.8 can be used to rectify the right adjoint right inverse adjunction \( r p \kappa \dashv \chi \) of (iii) to an adjunction that is fibered over \( \text{Hom}_B(B,p) \). So when Theorem 5.2.10(iii) holds, we may model the postulated adjunction by a fibered right adjoint to the isofibration \( r p \kappa \).

PROOF. We will prove \((i) \Rightarrow (iii) \Rightarrow (ii) \Rightarrow (i)\) and demonstrate the equivalences \((iv) \Leftrightarrow (vi)\) and \((iv) \Leftrightarrow (v)\) in parallel.

\((i) \Rightarrow (iii)\): If \( p : E \to B \) is cartesian, then the right comma cone over \( p \) admits a cartesian lift along \( p \),

\[
\begin{array}{ccc}
\text{Hom}_B(B,p) & \xrightarrow{p_1} & E \\
\downarrow{p_0} & & \downarrow{p} \\
B & \xleftarrow{\phi} & B
\end{array}
\]

\[
\begin{array}{ccc}
\text{Hom}_B(B,p) & \xleftarrow{\chi} & E \\
\downarrow{r} & & \downarrow{p} \\
B & \xleftarrow{\phi} & B
\end{array}
\]

defining a functor \( r : \text{Hom}_B(B,p) \to E \) over \( B \) together with a \( p \)-cartesian transformation \( \chi : r \Rightarrow p_1 \). By 1-cell induction, this generic \( p \)-cartesian transformation is represented by a functor

\[
\begin{array}{ccc}
\text{Hom}_B(B,p) & \xrightarrow{\chi} & E \\
\downarrow{p_1} & & \downarrow{p_0} \\
E & \xrightarrow{p} & E
\end{array}
\]

\[
\begin{array}{ccc}
\text{Hom}_B(B,p) & \xleftarrow{\chi} & E \\
\downarrow{p_1} & & \downarrow{p_0} \\
E & \xleftarrow{p} & E
\end{array}
\]

which we take as our definition of the putative right adjoint \( \chi^* \). By the definition of these adjoints, \( \phi \kappa^* \chi^* = p \kappa^* \chi^* = p \chi = \phi \), so Proposition 3.4.7 supplies a fibered isomorphism \( \bar{\varepsilon} : r p \kappa \chi^* \cong \text{id} \) with \( p_0 \bar{\varepsilon} = id_{p_0} \) and \( p_1 \bar{\varepsilon} = id_{p_1} \).

To prove that \( r p \kappa \dashv \chi \), it remains to define the unit 2-cell \( \bar{\eta} : \text{id} \Rightarrow \chi^* r p \kappa \), which we do by 2-cell induction from a pair given by an identity 2-cell \( p_1 \bar{\eta} = id_{p_1} \) and a 2-cell \( p_0 \bar{\eta} \) that remains to be
specified. Since \( p_1 \eta = \text{id} \), the required compatibility condition of Proposition 3.4.6(ii) asserts that this \( p_0 \eta \) must define a factorization of the generic arrow

\[
\begin{array}{c}
p_0 \\
\downarrow p_0 \eta
\end{array}
\begin{array}{c}
\kappa
\end{array}
\begin{array}{c}
p_1
\end{array}
\]

through \( \kappa^* \chi^* p \kappa^* = \chi^* p \kappa^* \). Note \( p \kappa = \phi^* p \kappa^* \) has \( \chi^* p \kappa^* \) as its \( p \)-cartesian lift, so we define \( p_0 \eta \) by the induction property of Proposition 5.1.11 for the cartesian transformation \( \chi^* p \kappa^* \) applied to the pair \((\kappa, \text{id})\) so that by construction (5.2.13) commutes and \( p p_0 = \text{id} \).

By Lemma 2.1.11, to prove that \( \eta^* \chi^* \) is invertible, it suffices to verify that \( \eta^* p \kappa^* \eta \) and \( \eta^* \chi^* \) are invertible. Then this data this together with \( \tilde{e} : \eta^* p \kappa^* \eta \cong \text{id} \) defines an adjunction with invertible counit. We deduce that \( \eta^* p \kappa^* \eta \) is invertible by 2-cell conservativity, since \( p_1 \eta^* p \kappa^* \eta = p_1 \eta = \text{id} \) and \( p_0 \eta^* p \kappa^* \eta = p p_0 \eta = \text{id} \).

Similarly, by 2-cell conservativity, to conclude that \( \eta^* \chi^* \) is invertible, it suffices to prove that \( p_0 \eta^* \chi^* \) is invertible. Restricting (5.2.13) along the functor \( \eta^* \chi^* \), we see that \( p_0 \eta^* \chi^* \) defines a fibered isomorphism of \( p \)-cartesian transformations

\[
\begin{array}{c}
r
\end{array}
\begin{array}{c}
\eta^* \chi^* p \kappa^* = r^* p \kappa^* \chi^*
\end{array}
\begin{array}{c}
\chi
\end{array}
\begin{array}{c}
p_0 \eta^* \chi^* p \kappa^* = r^* p \kappa^* \chi^*
\end{array}
\begin{array}{c}
p_1
\end{array}
\]

so is invertible by Lemma 5.1.10.

Finally note that a transformation \( \psi : e' \Rightarrow e \) is \( p \)-cartesian if and only if its factorization through the generic \( p \)-cartesian lift of \( p \psi \) is invertible. Since \( \kappa^* \psi^* = \psi \), this factorization may be constructed by restricting the 2-cells of (5.2.13) along the functor \( \psi^* : X \Rightarrow E^2 \), so we see that \( \psi \) is \( p \)-cartesian if and only if \( p_0 \eta^* \psi^* \) is invertible. By 2-cell conservativity, since \( p_1 \eta = \text{id} \), \( \eta^* \psi^* \) is invertible if and only if its domain component \( p_0 \eta^* \psi^* \) is invertible. This proves that \((\text{iv}) \Leftrightarrow (\text{vi})\).

\((\text{iii}) \Rightarrow (\text{ii})\): By Remark 5.2.12, we can model the left adjoint of \((\text{iii})\) by an isofibration \( \eta^* p \kappa^* : E^2 \Rightarrow \text{Hom}_B(B, p) \) and use Lemma 3.6.8 to rectify the right adjoint right inverse adjunction \( \eta^* p \kappa^* \Rightarrow \eta^* \chi^* \) into a fibered adjunction over \( \text{Hom}_B(B, p) \). Composing with the projection \( p_0 : \text{Hom}_B(B, p) \Rightarrow B \), Lemma 3.6.6(ii) then gives us a fibered adjunction over \( B \)

\[
\begin{array}{c}
E^2 \\
\downarrow p p_0
\end{array}
\begin{array}{c}
\perp
\end{array}
\begin{array}{c}
\text{Hom}_B(B, p)
\end{array}
\]

The 1-cell \( \eta^* \text{id} : E \Rightarrow E^2 \) induced by the identity may be defined by restricting along the functor \( ! : 2 \Rightarrow 1 \), and in this way is seen to be right adjoint right inverse to the codomain-projection functor

\[\text{By Lemma B.4.2, an application of this result, we may take } \tilde{e} \text{ to be the counit of the adjunction at the cost of modifying the } \eta \text{ by an isomorphism to define the unit.}\]
$p_1$ as well as a left adjoint right inverse to the domain-projection functor $p_0$:

$$\begin{array}{c}
1 \\
\downarrow 1 \quad \downarrow 0 \\
\uparrow 1 \quad \uparrow 0
\end{array} ~ \iff ~ \begin{array}{c}
E \\
\downarrow 1 \quad \downarrow 0 \\
\uparrow 1 \quad \uparrow 0
\end{array} \rightarrow E^2 \quad (5.2.14)
$$

This supplies a fibered adjunction $\overset{\text{id}}{\to} p_0$ over $E$ that we compose along $p : E \to B$ to a fibered adjunction over $B$:

$$\begin{array}{c}
E \\
\downarrow p_0 \quad \downarrow p_0 \quad \downarrow p_0
\end{array} \dashv \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array} \quad \begin{array}{c}
B \\
\uparrow p_0 \\
\uparrow p_0 \\
\uparrow p_0
\end{array} \quad \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array} \quad \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array}$$

This pair of fibered adjunctions composes to define a fibered adjunction over $B$ with left adjoint $\overset{\text{id}}{\to} p_0$ and right adjoint $\overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0$. Since both $\overset{\text{id}}{\to} p_0$ and $\overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0$ define functors $E \to \text{Hom}_B(B, p)$ are induced by the identity $\text{id}_p$ over the right comma cone over $p$, Proposition 3.4.7 supplies a fibered isomorphism $\overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0$. Applying Lemma 2.1.10 in the sliced $\infty$-cosmos over $B$, we can compose with this fibered isomorphism to obtain the desired adjunction:

$$\begin{array}{c}
E \\
\downarrow p_0 \quad \downarrow p_0 \quad \downarrow p_0
\end{array} \dashv \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array} \quad \begin{array}{c}
B \\
\uparrow p_0 \\
\uparrow p_0 \\
\uparrow p_0
\end{array} \quad \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array} \quad \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array}$$

proving (ii).

Note that by Proposition 2.1.9 the counit $\varepsilon$ of the composite adjunction is defined to be

$$\begin{array}{c}
E \\
\downarrow p_0 \quad \downarrow p_0 \quad \downarrow p_0
\end{array} \dashv \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array} \quad \begin{array}{c}
B \\
\uparrow p_0 \\
\uparrow p_0 \\
\uparrow p_0
\end{array} \quad \begin{array}{c}
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0 \\
\overset{\text{id}}{\to} p_0
\end{array}$$

where $\nu$ is the counit of the adjunction $\overset{\text{id}}{\to} p_0 \overset{\text{id}}{\to} p_0$, and by Remark 5.2.12 we may take $\overline{\varepsilon}$ to be the identity. Thus $p_1 \varepsilon = p_1 \overset{\text{id}}{\to} p_0 \nu \overset{\text{id}}{\to} \chi = p_1 \nu \chi$. By inspection, $p_1 \nu = \kappa$, the generic arrow over $E$, so $p_1 \varepsilon = p_1 \nu \chi = \kappa \chi = \chi$. This explains our strategy for proving the remaining implication.
(ii)⇒(i): Now suppose given a fibered adjunction

\[ E \xleftarrow{r_{id_p}} \perp \text{Hom}_B(B,p) \]

We will show that the codomain component of the counit

\[ \text{Hom}_B(B,p) \xrightarrow{\phi} \text{Hom}_B(B,p) \xrightarrow{p_1} E \]

satisfies the conditions of the generic \( p \)-cartesian transformation described in Lemma 5.2.5. By Lemmas 5.1.9 and 5.1.10, this will then also demonstrate the equivalence (iv)⇔(v).

The first thing to check is that \( p_1 \epsilon \) defines a lift of the right comma cone \( \phi \) over \( p \). To see this, consider the horizontal composite:

\[ \text{Hom}_B(B,p) \xrightarrow{\phi} \text{Hom}_B(B,p) \]

Naturality of whiskering provides a commutative square

\[ \begin{array}{ccc}
  p_0 & \xrightarrow{id_p} & p_0 \\
  \phi \xrightarrow{id_p} & & \phi \\
  pp_1 & \xrightarrow{id_p} & pp_1 
\end{array} \]

in which \( p_0 \epsilon = id \), as a fibered counit, and \( \phi \xrightarrow{id_p} = id \), since \( \phi \xrightarrow{id_p} = id_p \). So \( pp_1 \epsilon = \phi \), and thus \( p_1 \epsilon \) is a lift of \( \phi \) along \( p \).

It remains only to verify that \( p_1 \epsilon : r \Rightarrow p_1 \) defines a \( p \)-cartesian transformation, satisfying the condition of Definition 5.1.1:

\[ \text{Hom}_E(E,r) \xrightarrow{r_{p_1 \epsilon}} \text{Hom}_E(E,p_1) \]

By Lemma 3.6.6, the adjunction of (ii) defines an (unfibered) adjunction

\[ E \xleftarrow{r_{id_p}} \perp \text{Hom}_B(B,p) \]
By Proposition 4.1.1, pasting with the counit defines a fibered equivalence

\[
\begin{array}{ccc}
\text{Hom}_E(E,r) & \overset{\sim}{\longrightarrow} & \text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p)) \\
 E \times \text{Hom}_B(B,p) & & \\
\end{array}
\]

where, by inspection, the codomain comma $\infty$-category is defined by the pullback

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p)) & \rightarrow & \text{Hom}_{B^2}(\Delta p, B^2) \\
 & \downarrow & \downarrow j \\
 E^2 & \rightarrow & \text{Hom}_B(p,B) \\
 & \rightarrow & E \\
\end{array}
\]

where

\[
\begin{array}{ccc}
E^2 & \rightarrow & \text{Hom}_B(p,B) \\
 & \rightarrow & E \\
\end{array}
\]

Hence, it follows from the equivalence $B^{1\times2} \simeq B^{1\times2}$ of Proposition 4.2.7, that the comma $\infty$-categories are equivalent to the pullback

\[
\text{Hom}_E(E,r) \simeq \text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p)) \simeq E^2 \times B^3
\]

of $p^2$ along the restriction along the map $\delta^1: \mathbb{2} \hookrightarrow \mathbb{3}$. By Remark 5.2.7 and the weak pullback hypercube (5.2.8), this tells us that $\text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p))$ is the weak pullback of the cospan that expresses the universal property of the generic $p$-cartesian lift. It remains only to verify that the map

\[
\text{Hom}_E(E,r) \simeq \text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p)) \simeq E^2 \times B^3
\]

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_B(B,p)}(\text{id}_p,\text{Hom}_B(B,p)) & \rightarrow & \text{Hom}_{E^1}(E,r) \\
 & \downarrow & \downarrow j \\
 E^2 & \rightarrow & E \\
 & \rightarrow & B \\
\end{array}
\]

which is sent to the data displayed above-right in $E^2 \times B^3 \simeq \text{Hom}_E(E,p_1)$, as expected. □

One of the myriad applications of Theorem 5.2.10 is:

5.2.15. COROLLARY. Cosmological functors preserve cartesian fibrations and cartesian natural transformations.

163
Proof. By Theorem 5.2.10(iii), an isofibration \( p : E \to B \) in an \( \infty \)-cosmos \( \mathcal{K} \) is cartesian if and only if the isofibration \( \overline{p\kappa} : E^2 \to \text{Hom}_B(B,p) \) defined in Remark 5.2.12 admits a right adjoint right inverse. A cosmological functor \( F : \mathcal{K} \to \mathcal{L} \) preserves the class of isofibrations and the simplicial limits that define this map \( \overline{p\kappa} \). Since the 2-functor \( \mathbb{h}\mathcal{K} \to \mathbb{h}\mathcal{L} \) associated to a cosmological functor preserves adjunctions and the invertibility of 2-cells, \( F \) preserves cartesian fibrations, and the internal characterization of \( p \)-cartesian natural transformations given in Theorem 5.2.10(vi) is preserved similarly. □

Examples of cartesian fibrations are overdue.

5.2.16. Proposition (domain-projection fibration). For any \( \infty \)-category \( A \), the domain-projection functor \( p_0 : A^2 \to A \) defines a cartesian fibration. Moreover, a natural transformation \( \psi \) with codomain \( A^2 \) is \( p_0 \)-cartesian if and only if \( p_1 \psi \) is invertible.

Before giving the proof, we explain the idea. A natural transformation

\[
\begin{array}{ccc}
X & \xrightarrow{\beta} & A^2 \\
\downarrow{\alpha} & & \downarrow{p_0} \\
A & & A
\end{array}
\]

defines a composable pair of 2-cells \( \alpha : a \Rightarrow x \) and \( \beta : x \Rightarrow y \) in \( \text{hFun}(X,A) \). Composing these we induce a 2-cell

\[
\begin{array}{ccc}
X & \xrightarrow{\psi} & A^2 \\
\alpha & & \beta \\
\beta \alpha & & \beta \\
\end{array}
\]

representing the commutative square in \( \text{hFun}(X,A) \)

\[
\begin{array}{ccc}
a & \xrightarrow{\alpha} & x \\
\downarrow{\beta \alpha} & & \downarrow{\beta} \\
y & = & y
\end{array}
\]

so that \( p_0 \psi = \alpha \), as required, and \( p_1 \psi = \text{id} \).

Proof. We use Theorem 5.2.10(iii) and prove that \( p_0 \) is cartesian by constructing an appropriate adjoint to the functor

While the weak universal property of the arrow \( \infty \)-category can be used to induce 2-cells with codomain \( A^2 \), it cannot be used to prove equations between the induced 2-cells, as required to demonstrate that induction condition of Definition 5.1.1. Thus, some sort of \( \infty \)-cosmos-level argument is necessary to establish this result.
defined by cotensoring with the 1-categories displayed above right.°

To construct a right adjoint right inverse to the map $p_0\kappa$, it suffices to construct a left adjoint left inverse to the inclusion of 1-categories $k: \mathfrak{3} \hookrightarrow 2 \times 2$ with image $(0, 0) \to (0, 1) \to (1, 1)$. The left adjoint $\ell: 2 \times 2 \to \mathfrak{3}$ is a left inverse on the image of $\mathfrak{3}$ and sends $(1, 0)$ to the terminal element of $\mathfrak{3}$:

$$
\begin{align*}
2 \times 2 \ni & (0,0) \xrightarrow{} (0,1) \\
& \downarrow \quad \downarrow \\
(1,0) \xrightarrow{} (1,1) \\
\end{align*}
\mapsto
\begin{align*}
0 \xrightarrow{} 1 \\
\downarrow \quad \downarrow \\
2 \xrightarrow{} 2 \\
\end{align*}
\in \mathfrak{3}
$$

Now

$$
(A^2)^2 \xrightarrow{p_0\kappa=A^k} A^3 \cong \text{Hom}_A(A,p_0)
$$
defines the desired right adjoint right inverse.

The characterization of $p_0$-cartesian transformations now follows from Theorem 5.2.10(vi). A cell $\psi$ with codomain $A^2$ is $p_0$-cartesian if and only if its representing element of $(A^2)^2$ is in the essential image of the right adjoint $A^\ell: A^3 \to A^{2\times 2}$. Clearly if $\psi$ is in the essential image then its codomain component must be invertible.

Conversely, suppose the codomain component

$$
X \xrightarrow{\psi^*} A^{2\times 2} \xrightarrow{\epsilon_n(1,-)} A^2
$$
represents a natural isomorphism. Applying Lemma 1.1.12 to $\text{Fun}(X,A)$ one can build a diagram in $\text{Fun}(X,A)^{2\times 2} \cong \text{Fun}(X,A^{2\times 2})$ whose top edge is the given isomorphism, whose vertical edges are isomorphisms, and whose bottom edge is an identity. This glues onto $\psi$ to define a diagram $X \to A^{\Lambda[2] \times 2}$ and now the restriction

$$
X \xrightarrow{} A^{\Lambda[2] \times 2} \xrightarrow{} A^{3 \times 2} \xrightarrow{A^{\ell \times 2}} A^{2 \times 2 \times 2}
$$
along the surjective functor $\epsilon: 2 \times 2 \to \mathfrak{3}$ that sends $(0,0)$ and $(0,1)$ to $0$, which by Corollary 1.1.21 witnesses an isomorphism between $\psi^*$ and a diagram in the image of $A^\ell$, whose codomain component is the identity. □

On account of the pullback square

$$
\text{Hom}_A(f,g) \xrightarrow{j} \text{Hom}_A(A,g) \\
\downarrow p_0 \quad \downarrow p_0 \\
B \xrightarrow{f} A
$$

and Proposition 5.2.4, this result can be generalized to domain projections associated to any comma $\infty$-category, once we extend Proposition 5.2.16 to the domain-projection functor $p_0: \text{Hom}_A(A,g) \to A$.

°The cotensor $A(-)$ carries pushouts of simplicial sets to pullbacks of $\infty$-categories, and the pushout of $2 \cup_1 2$ of simplicial sets is $\Lambda[2]$, not $\mathfrak{3} = \Delta[2]$. However, on account of the equivalence of $\infty$-categories $A^3 \cong \Lambda[2]$, no harm comes from making the indicated substitution.
There is a sense in which this functor can be understood as a pullback of $p_0: A^2 \to A$, which we explain in the proof of Corollary 5.6.16 where this result appears. Alternatively, the reader is invited to prove that it is a cartesian fibration directly in Exercise 5.2.iv.

For $\infty$-categories admitting pullbacks, the codomain-projection functor also defines a cartesian fibration:

5.2.17. PROPOSITION (codomain-projection fibration). Let $A$ be an $\infty$-category that admits pullbacks in the sense of Definition 4.3.9. Then the codomain-projection functor $p_1: A^2 \to A$ is a cartesian fibration and the $p_1$-cartesian arrows are just those 2-cells that represent pullback squares.

PROOF. Via Theorem (iii), we desire a right adjoint right inverse to the functor $\lbrack p_1 \gamma \rbrack$ defined below-left applying $A^\sim$ to the diagram of simplicial sets appearing below-right:

This is provided by Corollary 4.3.5:

$$\text{res} \begin{array}{c} \rightarrow \\ \text{ran} \end{array} A^\sim \cong \text{Hom}(A, p_1)$$

There is a fourth equivalent definition of cartesian fibrations that we might have added to Theorem 5.2.10, except that it is an “external characterization” of cartesian fibrations, phrased entirely in the setting of the homotopy 2-category, rather than an “internal characterization,” that is amenable for proving that cartesian fibrations are preserved by cosmological functors.

5.2.18. PROPOSITION. Let $p: E \to B$ be an isofibration in an $\infty$-cosmos $\mathcal{K}$. Then $p$ is a cartesian fibration if and only if any natural transformation $\beta: b \Rightarrow pe$ admits a lift $\gamma: e' \Rightarrow e$ so that for any functor $f: Y \to X$ the 2-cell $\chi_{\beta}^f$ satisfies the following properties in the homotopy 2-category $\mathcal{K}$:

(i) induction: Given any natural transformations $\tau: e'' \Rightarrow ef$ and $\gamma: pe'' \Rightarrow pe'f$ so that $p\tau = \beta f \cdot \gamma$, there exists a lift $\tilde{\gamma}: e'' \Rightarrow e'f$ of $\gamma$ so that $\tau = \chi_{\beta}^f \cdot \tilde{\gamma}$.

(ii) conservativity: Any fibered endomorphism of $\chi_{\beta}^f$ is invertible: if $\zeta: e'f \Rightarrow e'f$ is any natural transformation so that $\chi_{\beta}^f \cdot \zeta = \chi_{\beta}^f$ and $p\zeta = \text{id}_{pe'f}$ then $\zeta$ is invertible.

Moreover, under these hypothesis, a natural transformation $\psi: e' \Rightarrow e$ with codomain $E$ is $p$-cartesian if and only if $\psi$ satisfies the induction and conservativity conditions.
To help us stay organized during the proof, we refer to a natural transformation \( \psi \colon e' \Rightarrow e \) satisfying conditions (i) and (ii) as a weak \( p \)-cartesian transformation. We will see that when \( p \) is a cartesian fibration, the class of weak \( p \)-cartesian transformations coincides with the class of \( p \)-cartesian transformations.

**Proof.** If \( p \colon E \rightarrow B \) is a cartesian fibration, then any \( \beta \colon b \Rightarrow pe \) admits a \( p \)-cartesian lift \( \chi \beta \) with codomain \( e \). By Lemma 5.1.6, the restriction \( \chi \beta f \) along any functor is again a \( p \)-cartesian transformation. By Proposition 5.1.11, this \( \chi \beta f \) then satisfies the induction and conservativity properties. In fact Proposition 5.1.11 shows more generally that any \( p \)-cartesian transformation is weakly \( p \)-cartesian.

Conversely, assume that \( p \colon E \rightarrow B \) satisfies the hypotheses of the statement. We will use the induction and conservativity properties associated to the lift\( \Hom_B(B, p) \)

\[
\begin{array}{ccc}
E & \xrightarrow{p} & B \\
\downarrow\psi & & \downarrow\phi \\
E & \xrightarrow{p} & B
\end{array}
\]

of the right comma cone \( \phi \) over \( p \) and its restrictions to construct the data of Theorem 5.2.10(ii).

Firstly, we apply the induction property to \( \chi \id_p^{-1} \cdot \eta \) to induce a 2-cell \( \eta \colon \id_E \Rightarrow r \) so that \( p\eta = \id_p \) and \( \chi \id_p^{-1} \cdot \eta = \id \). Since any isomorphism with codomain \( E \) is \( p \)-cartesian, such 2-cells also define weak \( p \)-cartesian transformations. These weak universal properties suffice to show that the fibered set \( \eta \) is an isomorphism, and indeed the inverse isomorphism to \( \chi \id_p^{-1} \).

We induce the counit \( \epsilon : \id_p \Rightarrow \id_E \) by 2-cell induction from the pair of 2-cells \( p\epsilon = \id \) and \( p_1 \epsilon = \chi \). Now \( \epsilon \id_p^{-1} \) is induced from a pair of invertible 2-cells, and thus must be an isomorphism by 2-cell conservativity. The 2-cell \( \epsilon \) can also be seen to be invertible, on account of the naturality of whiskering square associated to the horizontal composite:

\[
\begin{array}{ccc}
E & \xrightarrow{r \id_p^{-1} \epsilon} & E \\
\downarrow\epsilon & & \downarrow\epsilon \\
E & \xrightarrow{p_1 \epsilon = \chi} & E
\end{array}
\]

By the analogue of Lemma 5.1.9 for weak \( p \)-cartesian cells, the top right composite is weakly \( p \)-cartesian. Since \( p\epsilon = p_0 \epsilon = \id \), we can apply the induction and conservativity properties once more to induce a transformation \( \gamma : r \Rightarrow r \id_p^{-1} \cdot \epsilon \) so that \( \gamma \cdot \epsilon \) and \( \epsilon \cdot \gamma \) are both isomorphisms. Hence \( \epsilon \) is invertible.

By Lemma 2.1.11 this data suffices to define an adjunction in the sliced homotopy 2-category \( (\mathcal{K})_B \).

By Lemma 3.6.7, this adjunction may then be lifted along the smothering 2-functor \( b(\mathcal{K})_B \rightarrow (\mathcal{K})_B \) of Proposition 3.6.2 to a genuine fibered adjunction. By Theorem 5.2.10(ii), this proves that \( p \) is a cartesian fibration.

Finally, observe that when \( p \) is a cartesian fibration, any weakly \( p \)-cartesian transformation \( \psi \colon e' \Rightarrow e \) is fibered isomorphic to a \( p \)-cartesian lift of \( p\psi \) with codomain \( e \). By Lemma 5.1.9, it follows that \( \psi \) is then a \( p \)-cartesian transformation, proving that when \( p \) is a cartesian fibration these classes coincide.

\( \square \)

**Exercises.**
5.2.i. **Exercise.** There is a standard notion of cartesian fibration in a 2-category developed by Street [113] that recovers the Grothendieck fibrations when specialized to the 2-category Cat. This is not the correct notion of cartesian fibration between $\infty$-categories as the universal property the usual notion demands of lifted 2-cells is too strict. Compare this definition with 2-categorical definition of Proposition 5.2.18 and consider why the stricter universal property does not hold in the $\infty$-categorical context, for instance by considering the cartesian fibrations of Proposition 5.2.16.

5.2.ii. **Exercise.** Let $\chi: r \Rightarrow p_1$ denote the generic $p$-cartesian transformation associated to an isofibration $p: E \to B$. The pullback that defines $\text{Hom}_E(E, r)$ factors as

$$\begin{array}{c}
\text{Hom}_E(E, r) \xrightarrow{\alpha} E^3 \xrightarrow{p_{01}} E^2 \\
\downarrow \quad \quad \downarrow p_{12} \\
\text{Hom}_B(B, p) \xrightarrow{\chi} E^2 \xrightarrow{p_0} E
\end{array}$$

where the right-hand square is a weak pullback. Use this to describe the map induced by $\chi$ from $\text{Hom}_E(E, r)$ to the initial object in the pullback hypercube (5.2.8).

5.2.iii. **Exercise.** Show that a cartesian fibration $p: E \to B$ defines an “incoherent pseudofunctor” $E: hB^{op} \to hK$ given by the data:

- a mapping on objects $b \in hB \mapsto E_b \in hK$;
- a mapping on 1-cells $\beta: a \to b \in hB \mapsto \beta^*: E_b \to E_a \in hK$ defined by (5.0.1);
- an invertible 2-cell $E_b \xrightarrow{\eta_b \equiv} E_b$ for each $b \in hB$; and
- an invertible 2-cell

$$\gamma^* \xrightarrow{\alpha \beta \gamma \equiv} E_b \xrightarrow{\beta^*} E_a$$

in $hK$ for each composable pair of morphisms in $hB$.

The coherence conditions present in the full definition of a pseudo-functor, which appears as Definition 10.4.1, are not evidently satisfied here, but do follow from the extension of this construction to a homotopy coherent diagram indexed by the underlying quasi-category of $B$ [107, 6.1.16].

5.2.iv. **Exercise (5.6.16).** Use either Theorem 5.2.10(ii) or (iii) to prove that for any functors $C \xrightarrow{g} A \xleftarrow{f} B$ between $\infty$-categories, the domain-projection functor $p_0: \text{Hom}_A(f, g) \to B$ is a cartesian fibration, and moreover, a natural transformation $\psi$ with codomain $\text{Hom}_A(f, g)$ is $p_0$-cartesian if and only if $p_1 \psi$ is invertible.\(^{10}\)

5.2.v. **Exercise.** Given an alternate proof of Proposition 4.3.11 using results from this chapter.

\(^{10}\)The reader opting to reprise the proof of Proposition 5.2.16, might wish to appeal to Proposition 6.4.9 if this construction proves too painful.
5.3. Cartesian Functors

While it can be argued directly from the original definition that cartesianness is an equivalence-invariant property of isofibrations, we find it expedient to appeal to Theorem 5.2.10 so that we can study the relationship between the data that witnesses the cartesianness of an isofibration and that data provided by an equivalence.

5.3.1. Corollary. Consider an essentially commutative square between isofibrations whose horizontal functors are equivalences:

\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
\downarrow q & \equiv & \downarrow p \\
A & \xrightarrow{k} & B
\end{array}
\]

Then \( p \) is a cartesian fibration if and only if \( q \) is a cartesian fibration in which case \( h \) preserves and reflects cartesian transformations: \( \psi \) is \( q \)-cartesian if and only if \( h\psi \) is \( p \)-cartesian.

Proof. By Proposition 3.4.6, an essentially commutative square induces an essentially commutative square

\[
\begin{array}{ccc}
F^2 & \xrightarrow{h^2} & E^2 \\
\downarrow \circlearrowright_{q,c^*} & \equiv & \downarrow \circlearrowright_{p,c^*} \\
\Hom_A(A, q) & \xrightarrow{\sim} & \Hom_B(B, p)
\end{array}
\]

whose horizontal functors are the equivalences defined in Proposition 3.4.5. By the equivalence-invariance of adjunctions—Proposition B.3.8—the left-hand vertical functor admits a right adjoint right inverse if and only if the right-hand vertical functor does. By Theorem 5.2.10(iii), it follows that \( p \) is cartesian if and only if \( q \) is cartesian.

When adjoints exist they are uniquely determined up to isomorphism, so when \( p \) and \( q \) are cartesian fibrations we may assume that their witnessing adjunctions of Theorem 5.2.10(iii) are constructed as described in Proposition B.3.8. In particular, this construction reveals that the whiskered composites \( h^2 \eta \) and \( \eta h^2 \) of the units of the respective adjunctions are isomorphic. Hence the component at an element \( \psi^* : X \to F^2 \) of \( h^2 \eta \) is invertible if and only if the component of \( \eta h^2 \) is invertible; since \( h^2 \) is an equivalence, the former is the case if and only if the component of \( \eta \) is invertible. By Theorem 5.2.10(vi), this proves that \( \psi \) is \( p \)-cartesian if and only if \( h\psi \) is \( q \)-cartesian.

We have now met a few examples of our preferred notion of morphism between cartesian fibrations:

5.3.2. Definition (cartesian functor). Let \( p : E \to B \) and \( q : F \to A \) be cartesian fibrations. A commutative square

\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
\downarrow q & \equiv & \downarrow p \\
A & \xrightarrow{k} & B
\end{array}
\]

defines a cartesian functor if \( h \) preserves cartesian transformations: if \( \psi \) is \( q \)-cartesian then \( h\psi \) is \( p \)-cartesian.
For the purposes of Proposition 6.4.13, we prefer to reserve this terminology for strictly commutative squares, but it can easily be extended to essentially commutative squares; see Exercise 5.3.ii.

5.3.3. Example (pullbacks and equivalences are cartesian). Immediately from Proposition 5.2.4 and Corollary 5.3.1, both pullback squares and commutative squares of equivalences define cartesian functors, which in these cases have the special property that the top horizontal functor reflects, as well as preserves, cartesian transformations. These results extend to weak pullback squares, since any weak pullback square factors as

\[
\begin{array}{ccc}
F & \sim & P \\
\downarrow q & & \downarrow a \\
A & \cong & A
\end{array}
\]

where \(P\) is the strict pullback, and cartesian functors are easily seen to compose.

The internal characterization of cartesian fibrations of Theorem 5.2.10 extends to an internal characterization of cartesian functors.

5.3.4. Theorem (an internal characterization of cartesian functors). For a commutative square

\[
\begin{array}{ccc}
F & \sim & E \\
\downarrow q & & \downarrow p \\
A & \cong & B
\end{array}
\]

between cartesian fibrations the following are equivalent:

(i) The square \((h, k)\) defines a cartesian functor from \(q\) to \(p\).

(ii) The mate of the canonical isomorphism

\[
\begin{array}{ccc}
\Hom_A(A, q) & \cong & \Hom_B(B, p) \\
\downarrow r & & \downarrow r \\
\Hom_A(A, q) & \cong & \Hom_B(B, p)
\end{array}
\]

in the diagram of functors over \(f: A \to B\) is an isomorphism.

(iii) The mate of the canonical isomorphism

\[
\begin{array}{ccc}
\Hom_A(A, q) & \cong & \Hom_B(B, p) \\
\downarrow r & & \downarrow r \\
\Hom_A(A, q) & \cong & \Hom_B(B, p)
\end{array}
\]

in the diagram of functors is an isomorphism.

The mates referenced here generalize the notion of “adjoint” or “transposed” 2-cells; see Definition B.3.3 and §B.3. As in that case, the mate of an isomorphism is not necessarily invertible.

Proof. We will prove (i)\(\iff\)(ii) and (i)\(\iff\)(iii). The idea in each case is similar. Conditions (ii) and (iii) imply that \(h\) preserves the explicitly chosen cartesian lifts up to isomorphism, which by Lemma
5.1.8 implies that \( h \) preserves all cartesian lifts. Conversely, assuming (i), we need to show that a whiskered copy of the counit of \( \text{id}_q^\gamma \adj r \) and of the unit of \( \text{pk}^\gamma \adj \chi^\gamma \) are isomorphisms. The counit of \( \text{id}_q^\gamma \adj r \) and unit of \( \text{pk}^\gamma \adj \chi^\gamma \) each encode the data of the factorizations of a natural transformation through the cartesian lift of its projection. It will follow from (i) that the cells in question are cartesian and the factorizations live over identities, so Lemma 5.1.10 will imply that these natural transformations are invertible.

(i)⇔(iii): For convenience, we use the constructions of Remark 5.2.12 and Proposition 3.4.5 to define the functors involved so that the square on the left-hand side of (iii) commutes strictly. If we take the counits of this adjunctions to be identities, as Remark 5.2.12 permits, then the mate of this identity 2-cell is \( \overline{\eta}h^2\gamma^\chi^\gamma \). By Theorem 5.2.10(iv)⇔(vi), this component of \( \overline{\eta} \) is invertible if and only if \( h\chi \) is \( p \)-cartesian, where \( \chi \) is the generic \( q \)-cartesian lift of Lemma 5.2.5 for the cartesian fibration \( q: F \to A \). By that lemma again, \( h\chi \) is \( p \)-cartesian if and only if \( h \) preserves cartesian transformations, since the other \( q \)-cartesian lifts are isomorphic to restrictions of \( \chi \).

(i)⇔(ii): Let us write \( \hat{h} \) as an abbreviation for the functor \( \text{Hom}_k(k, h) \) to save space. Since the unit of \( \text{id}_p^\gamma \adj r \) is an isomorphism by Remark 5.2.11, the mate of the isomorphism on the left hand side of (ii) is isomorphic to \( p \hat{h}\epsilon = p_\epsilon \), so our task is to show that this natural transformation is invertible if and only if \( h \) defines a cartesian functor. This leads us to consider the naturality of whiskering square

\[
\begin{array}{ccc}
r\hat{h}\epsilon^r \text{id}_q^\gamma r & \xrightarrow{r\epsilon^r} & r\hat{h} \\
p_1r\hat{h}\epsilon^r \text{id}_q^\gamma r & \xrightarrow{p_1\epsilon r} & p_1r\hat{h}
\end{array}
\]

expressing the horizontal composite of the two counits:

\[
\begin{array}{ccccc}
r & F & \xleftarrow{r \text{id}_q^\gamma} & \xrightarrow{\epsilon} & E \\
\text{Hom}_A(A, q) & \xrightarrow{\epsilon^r} & \text{Hom}_B(B, p) & \xleftarrow{\text{id}_p^\gamma} & \text{Hom}_B(B, p)
\end{array}
\]

Since \( \epsilon \) is the counit of an adjunction \( \text{id}_p^\gamma \adj r \) with invertible unit, \( \epsilon^r \text{id}_p^\gamma \) is an isomorphism, so \( e\hat{h} \text{id}_q^\gamma \), which is isomorphic to \( \epsilon^r \text{id}_p^\gamma \epsilon \), is invertible. From the calculation \( pr\epsilon = p_0\epsilon = kp_0\epsilon = \epsilon \), we see that the top-horizontal 2-cell lies in a fiber over an identity.

Recall from Theorem 5.2.10(v) that \( p_1 \epsilon \) defines the generic \( p \)-cartesian lift of Lemma 5.2.5 for the cartesian fibration \( p: E \to B \). Hence the right-hand vertical 2-cell \( p_1\epsilon \hat{h} \) is a \( p \)-cartesian lift of \( \phi \epsilon \hat{h} \), where \( \phi \) is the right comma cone over \( p \). By the definition of \( \hat{h} \), \( \phi \epsilon \hat{h} = k\phi \), the latter \( \phi \) being the right comma cone over \( q \).

Similarly, the bottom horizontal 2-cell \( p_1\epsilon \hat{h} \) is a lift of \( k\phi = \phi \epsilon \hat{h} \). So if \( h \) is a cartesian functor, the right-hand vertical and bottom horizontal 2-cells are both \( p \)-cartesian lifts of a common 2-cell, and the conservativity property of Lemma 5.1.10 implies that \( r\hat{h} \epsilon \) is invertible. Conversely, if \( r\hat{h} \epsilon \) is invertible, the \( p_1\epsilon \hat{h} = hp_1 \epsilon \) is isomorphic to the \( p \)-cartesian transformation \( p_1\epsilon \hat{h} \) and is consequently \( p \)-cartesian.
Since every $q$-cartesian transformation is isomorphic to a restriction of $p_1 \epsilon$, this is the case if and only if $h$ is a cartesian functor.

Another family of examples of cartesian functors are given by the following lemma, which can be proven using Theorem 5.3.4.

5.3.5. Lemma. If

$$
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
\downarrow q & & \downarrow p \\
B & & \downarrow p
\end{array}
$$

is a functor between cartesian fibrations that admits a left adjoint over $B$, then $h$ defines a cartesian functor.

Proof. If $\ell$ is a fibered left adjoint to $h$ in an $\infty$-cosmos $\mathcal{K}$, then the cosmological functor defined by pullback $p_1^\ast : \mathcal{K}_B \to \mathcal{K}_{B^2}$ carries this fibered adjunction to a fibered adjunction

$$
\begin{array}{ccc}
\text{Hom}_{\mathcal{K}_B}(B, q) & \rightarrow & \text{Hom}_{\mathcal{K}_B}(B, p) \\
\downarrow \alpha & & \downarrow \beta \\
\text{Hom}(\mathcal{K}_B, id_B, h)
\end{array}
$$

Similarly, the cosmological functor $(\cdot)^2 : \mathcal{K} \to \mathcal{K}$ carries the adjunction $\ell \dashv h$ to an adjunction $\ell^2 \dashv h^2$.

Now both horizontal functors in the commutative square

$$
\begin{array}{ccc}
F^2 & \xrightarrow{h^2} & E^2 \\
\downarrow \gamma & & \downarrow \delta \\
\text{Hom}_{\mathcal{K}_B}(B, q) & \xrightarrow{\text{Hom}(\mathcal{K}_B, id_B, h)} & \text{Hom}_{\mathcal{K}_B}(B, p)
\end{array}
$$

admit left adjoints. A standard result from the calculus of mates tells us that the mate with respect to the vertical adjunctions is an isomorphism if and only if the mate with respect to the horizontal adjunctions is an isomorphism, the latter natural transformation between left adjoints being the transpose of the former natural transformation between their right adjoints; see Exercise B.3.iii. In the present context, the mate with respect to the horizontal adjunctions can be seen to be an isomorphism by 2-cell conservativity for $\text{Hom}_{\mathcal{K}_B}(B, q)$. □

Exercises.

5.3.i. Exercise. Show that the pullback of a cartesian functor $h$ between cartesian fibrations with a common base defines a cartesian functor

$$
\begin{array}{ccc}
& & F \\
& \searrow & l \\
\bullet & \xrightarrow{k} & E \\
& \downarrow q & & \downarrow p \\
A & \xrightarrow{k} & B
\end{array}
$$
5.3.ii. Exercise. Recall that any essentially commutative square
\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
q \downarrow & \cong & \beta' \\
A & \xrightarrow{k} & B
\end{array}
\]
can be rectified to a strictly commutative square by lifting the natural isomorphism along the isofibration \(p\), at the cost of replacing \(h\) by a naturally isomorphic functor. Declare an essentially commutative square between cartesian fibrations to define a cartesian functor if and only if its replacement by a strictly isomorphic commutative square satisfies the condition of Definition 5.3.2. Show that this relaxation of terminology is well-defined.

5.3.iii. Exercise. Show that cartesian functors compose both vertically and horizontally.

5.3.iv. Exercise. Categorify the intuition that cartesian fibrations \(p : E \rightarrow B\) and \(q : F \rightarrow B\) define “contravariant \(B\)-indexed functors valued in \(\infty\)-categories” by proving that a cartesian functor
\[
\begin{array}{ccc}
E & \xrightarrow{h} & F \\
\beta \downarrow & \cong & \beta' \\
E_a & \xrightarrow{\beta} & F_a
\end{array}
\]
defines a “natural transformation”: show that there exists a natural isomorphism in the square of fibers
\[
\begin{array}{ccc}
E_b & \xrightarrow{h} & F_b \\
\beta^\ast \downarrow & \cong & \beta'^\ast \\
E_a & \xrightarrow{\beta} & F_a
\end{array}
\]
where the action of an arrow \(\beta\) in the homotopy category of \(B\) on the fibers is defined by factoring the domain of a \(p\)- or \(q\)-cartesian lift of \(\beta\) as displayed in (5.0.1).

5.4. Cocartesian Fibrations and Bifibrations

We have seen that in a cartesian fibration that arrows in the homotopy category of the base act contravariantly on the fibers. Dually, in a cocartesian fibration, arrows in the homotopy category of the base act covariantly on the fibers. Recall from Definition 1.2.25 that for any \(\infty\)-cosmos \(\mathcal{K}\), there is a dual \(\infty\)-cosmos \(\mathcal{K}^{\text{co}}\) with the same objects but with functor spaces defined by:

\[
\text{Fun}_{\mathcal{K}^{\text{co}}}(A, B) := \text{Fun}_{\mathcal{K}}(A, B)^{\text{op}}.
\]
The isofibrations, equivalences, and trivial fibrations in \(\mathcal{K}^{\text{co}}\) coincide with those of \(\mathcal{K}\). Conical limits in \(\mathcal{K}^{\text{co}}\) coincide with those in \(\mathcal{K}\), while the cotensor of \(A \in \mathcal{K}\) with \(U \in s\text{Set}\) is defined to be \(A^{U^{\text{op}}}\). In particular, the cotensor of an \(\infty\)-category with \(\mathbb{Z}\) is defined to be \(A^{\mathbb{Z}^{\text{op}}}\), which exchanges the domain and codomain projections from arrow and comma \(\infty\)-categories.

With this structure in hand, we can succinctly define a cocartesian fibration in an \(\infty\)-cosmos \(\mathcal{K}\) to be an isofibration \(p : E \rightarrow B\) that defines a cartesian fibration in the dual \(\infty\)-cosmos \(\mathcal{K}^{\text{co}}\). Now all of the results proven in §5.1-5.3 develop the theory of cocartesian fibrations. In this section, we briefly review a few of the highlights before turning our attention to bifibrations, isofibrations that define both cartesian and cocartesian fibrations.
5.4.1. Definition (\(p\)-cocartesian transformation). Let \(p: E \to B\) be an isofibration. A natural transformation \(X \xrightarrow{\psi \beta} E\) with codomain \(E\) is \(p\)-\textit{cocartesian} if functors define a weak pullback square:

\[
\begin{array}{ccc}
\text{Hom}_E(e', E) & \xrightarrow{\psi^*} & \text{Hom}_E(e, E) \\
\downarrow \text{Hom}_p(id, p) & & \downarrow \text{Hom}_p(id, p) \\
\text{Hom}_B(pe', B) & \xrightarrow{\rho^*} & \text{Hom}_B(pe, B)
\end{array}
\]

meaning that the induced map

\[
\text{Hom}_E(e', E) \cong \text{Hom}_B(pe', B) \times_{\text{Hom}_B(pe, B)} \text{Hom}_E(e, E)
\]

is an equivalence.

5.4.2. Definition (cocartesian fibration). An isofibration \(p: E \to B\) is a \textit{cocartesian fibration} if any natural transformation \(\beta: pe \Rightarrow b\) as below-left admits a \(p\)-cartesian lift \(\chi\beta: e \Rightarrow \beta_*e\) as below-right:

\[
\begin{array}{ccc}
X \xrightarrow{e} E & \xrightarrow{\rho} & E \\
\downarrow \rho \beta & & \downarrow \rho \beta \\
B & \xrightarrow{p} & B
\end{array}
\quad\quad\quad
\begin{array}{ccc}
X \xrightarrow{e} E & \xrightarrow{\rho \chi \beta} & E \\
\downarrow \rho \beta & & \downarrow \rho \beta \\
B & \xrightarrow{p \chi \beta} & B
\end{array}
\]

As above, it suffices in Definition 5.4.2 to assume only that the generic transformation whose domain factors through \(p\) admits a \(p\)-cocartesian lift:

5.4.3. Lemma. An isofibration \(p: E \to B\) is a cocartesian fibration if and only if the left comma cone over \(p\) displayed below-left admits a \(p\)-cocartesian lift \(\chi\) as displayed below-right:

\[
\begin{array}{ccc}
\text{Hom}_B(p, B) & \xrightarrow{p_0} & E \\
\downarrow \psi \phi & & \downarrow p \\
B & \xrightarrow{\rho \chi} & B \\
p_1 & & p
\end{array}
\quad\quad\quad
\begin{array}{ccc}
\text{Hom}_B(p, B) & \xrightarrow{p_0} & E \\
\downarrow \psi \phi & & \downarrow p \\
B & \xrightarrow{\rho \chi} & B
\end{array}
\]

The dual to Theorem 5.2.10 asks for a fibered left adjoint to \(\rho \text{id}_p\): \(E \to \text{Hom}_B(p, B)\) and a left adjoint right inverse to \(\rho \rho^*\): \(E^2 \to \text{Hom}_B(p, B)\) in place of right adjoints. See Exercise 5.4.i.

Propositions 5.2.16 and 5.2.17 dualize to provide the following examples:

5.4.4. Proposition (codomain-projection fibration). For any \(\infty\)-category \(A\):

(i) The codomain-projection functor \(p_1: A^2 \to A\) defines a cocartesian fibration. Moreover, a natural transformation \(\psi\) with codomain \(A^2\) is \(p_1\)-cocartesian if and only if \(p_0 \psi\) is invertible.

(ii) If \(A\) has pushouts, then the domain-projection functor \(p_0: A^2 \to A\) defines a cocartesian fibration, for which the \(p_0\)-cocartesian cells are the pushout squares. \(\square\)

By this result and its dual, when \(A\) has pushouts, the domain-projection functor \(p_0: A^2 \to A\) is both a cartesian fibration and a cocartesian fibration. Such maps have a special property we now explore.
5.4.5. Definition (bifibration). An isofibration \( p: E \rightarrow B \) defines a **bifibration** if \( p \) is both a cartesian fibration and a cocartesian fibration.

Projections give trivial examples of bifibrations.

5.4.6. Example. For any ∞-categories \( A \) and \( B \) the projection functor \( \pi: A \times B \rightarrow B \) is a bifibration, in which a 2-cell with codomain \( A \times B \) is \( \pi \)-cocartesian or \( \pi \)-cartesian if and only if its composite with the projection \( \pi: A \times B \rightarrow A \) is an isomorphism.

5.4.7. Proposition. Let \( p: E \rightarrow B \) be a bifibration. Then any arrow \( X \xleftarrow{a} B \) induces a fibered adjunction

\[
\begin{array}{ccc}
E_a & \xleftarrow{\beta^*} & E_b \\
\downarrow p_a & & \downarrow p_b \\
X & \xrightarrow{\beta} & X
\end{array}
\]

between the fibers of \( p \) over \( a \) and \( b \).

**Proof.** Write \( \gamma^\beta: X \rightarrow B^2 \) for the functor induced by \( \beta \). Note that the pullbacks defining the fibers over its domain edge \( a \) and codomain edge \( b \) factor as:

\[
\begin{array}{ccc}
E_a & \xrightarrow{\beta^*} & E_b \\
\downarrow p_a & & \downarrow p_b \\
X & \xleftarrow{\beta} & X
\end{array}
\]

Now via Remark 5.2.12, Theorem 5.2.10(iii) and its dual provide a right adjoint right inverse to \( \gamma^\beta: E^2 \rightarrow \text{Hom}_B(B, p) \) and a left adjoint right inverse to \( \gamma^\beta: E^2 \rightarrow \text{Hom}_B(B, p) \). Composing the former fibered adjunction with \( q: \text{Hom}_B(B, p) \rightarrow B^2 \) and the latter fibered adjunction with \( q: \text{Hom}_B(B, p) \rightarrow B^2 \) we obtain a composable pair of adjunctions

\[
\begin{array}{ccc}
\text{Hom}_B(B, p) & \xleftarrow{\gamma^\beta} & \text{Hom}_B(B, p) \\
\downarrow q & & \downarrow r \chi \\
B^2 & \xrightarrow{\gamma^\beta} & B^2
\end{array}
\]

fibered over \( B^2 \); note in both cases that \( q^\gamma \chi^\beta = p^2 \). Pulling back the composite adjunction along \( \gamma^\beta: X \rightarrow B^2 \) yields the fibered adjunction of the statement. □

Note that the construction of the adjoint functors \( \beta^*, \beta^* \) given in this proof coincides with the description of the the action of the 2-cell \( \beta \) on the fibers of \( p \) given in Remark 5.2.9.
5.4.i. EXERCISE. Formulate the dual to Theorem 5.2.10, providing an internal characterization of cocartesian fibrations.

5.4.ii. EXERCISE. Suppose $A$ is an $\infty$-category with pullbacks. By Propositions 5.2.17 and 5.4.4, the codomain-projection functor $p_1: A^2 \to A$ is a bifibration. Describe the action of the left and right adjoints in the adjunction induced from an arrow $\alpha: x \to y$ in $\mathbf{h}A$:

\[
\begin{array}{c}
1 \\
\downarrow y \\
A \\
\downarrow x \\
\end{array} \quad \cong \quad \begin{array}{c}
\text{Hom}_A(A, x) \\
\downarrow \alpha_* \\
\text{Hom}_A(A, y) \\
\downarrow \alpha^* \\
\end{array}
\]

5.5. The Representability of Cartesian Fibrations

In this section, we reinterpret the notion of cartesian fibration and cartesian natural transformation from a point of view that emphasizes the $\infty$-cosmos $\mathcal{K}$, rather than its quotient homotopy 2-category $\mathbf{h}\mathcal{K}$. In doing so, we recall that the functors $e: X \to E$ between $\infty$-categories are precisely the vertices, or 0-arrows, in the quasi-categorical functor space $\text{Fun}(X, E)$; see Digression 1.2.4. The 1-simplices, or 1-arrows, $e': e$ of $\text{Fun}(X, E)$ represent natural transformations $X \xrightarrow{\chi} E$. Every natural transformation from $e'$ to $e$ is represented by a 1-arrow $e' \to e$ and a parallel pair of 1-arrows represent the same natural transformation if and only if they are homotopic, bounding a 2-arrow in $\text{Fun}(X, E)$ whose 0th or 2nd edge is degenerate.

Before analyzing the 0- and 1-arrows in the functor spaces in particular, we consider the collection of functor spaces of an $\infty$-cosmos globally and prove another important corollary of the internal characterization of cartesian fibrations. The notion of cartesian fibrations are representably defined in the following sense:

5.5.1. PROPOSITION. Let $p: E \to B$ be an isofibration between $\infty$-categories in an $\infty$-cosmos $\mathcal{K}$. Then $p$ is a cartesian fibration if and only if:

(i) For all $X \in \mathcal{K}$, the isofibration $p_*: \text{Fun}(X, E) \to \text{Fun}(X, B)$ is a cartesian fibration between quasi-categories.

(ii) For all $f: Y \to X \in \mathcal{K}$, the square

\[
\begin{array}{ccc}
\text{Fun}(X, E) & \xrightarrow{f_*} & \text{Fun}(Y, E) \\
\downarrow p_* & & \downarrow p_* \\
\text{Fun}(X, B) & \xrightarrow{f_*} & \text{Fun}(Y, B)
\end{array}
\]

is a cartesian functor.

PROOF. If $p: E \to B$ is a cartesian fibration, then Theorem 5.2.10(iii) constructs a right adjoint right inverse to $p_*: E^2 \to \text{Hom}_B(B, p)$. The simplicial bifunctor $\text{Fun}(-, -): \mathcal{K}^{\text{op}} \times \mathcal{K} \to \text{QCat}$ defines a 2-functor $\text{Fun}(-, -): \mathcal{K}^{\text{op}} \times \mathcal{K} \to \mathbf{h}\text{QCat}$, which transposes to a Yoneda-type embedding $\text{Fun}(-, -): \mathcal{K} \to \mathbf{h}\text{QCat}^{\text{op}}$ from the homotopy 2-category of $\mathcal{K}$ to the 2-category of 2-functors,
2-natural transformations, and modifications; see §B.2. This 2-functor carries the adjunction $^\circ p \kappa^\circ \dashv \chi^\circ$ to an adjunction in the 2-category $\mathcal{K}^{\text{op}}$. This latter adjunction defines, for each $X \in \mathcal{K}$, a right adjoint right inverse adjunction

$$\text{Fun}(X, E)^2 \cong \text{Fun}(X, E^2) \xrightarrow{\kappa^\circ_p \overset{\vdash}{\frown} f^*} \text{Fun}(Y, E)^2 \cong \text{Fun}(Y, E)$$

and for each $f : Y \to X$ in $\mathcal{K}$, a strict adjunction morphism\(^{11}\) commuting strictly with the left adjoints and with the right adjoints:

$$\text{Hom}(\text{Fun}(X, B), p_*) \cong \text{Fun}(X, \text{Hom}_B(B, p)) \xrightarrow{\vdash} \text{Fun}(Y, \text{Hom}_B(B, p)) \cong \text{Hom}(\text{Fun}(Y, B), p_*)$$

By Theorems 5.2.10(iii)$\Rightarrow$(i) and 5.3.4(iii)$\Rightarrow$(i), this demonstrates the two conditions of the statement.

Conversely, supposing $p : E \to B$ satisfies conditions (i) and (ii) by Theorems 5.2.10(iii) and 5.3.4(iii) there is a commutative square $^\circ p \kappa^\circ f^* = f^* p \kappa^\circ$ where both verticals $^\circ p \kappa^\circ$ admit right adjoint right inverses $^\circ \rho^* : \text{Fun}(X, E^2) \to \text{Fun}(X, \text{Hom}_B(B, p))$ to a functor $^\circ \chi^\circ : \text{Fun}(X, \text{Hom}_B(B, p)) \to \text{Fun}(X, E^2)$ arising from post-composition with some $^\circ \chi^\circ : \text{Hom}_B(B, p) \to E^2$. This right adjoint $^\circ \chi^\circ$ is extracted as the image of the identity element

$$\text{Fun}(\text{Hom}_B(B, p), \text{Hom}_B(B, p)) \xrightarrow{\rho} \text{Fun}(\text{Hom}_B(B, p), E^2)$$

and the unit and counit are internalized similarly; the condition on mates is used to verify the triangle equalities that demonstrate that $^\circ p \kappa^\circ \dashv ^\circ \chi^\circ$. Now Theorem 5.2.10(iii) proves that $p : E \to B$ is a cartesian fibration. \hfill \square

An easier argument along the same lines demonstrates:

5.5.3. **COROLLARY.** A commutative square between cartesian fibrations as displayed below-left

$$\begin{array}{ccc}
F \xrightarrow{h} E & \xrightarrow{h_\ast} \text{Fun}(X, F) \xrightarrow{h_\ast} \text{Fun}(X, E) \\
\downarrow q & \cong & \downarrow q_\ast \\
A \xrightarrow{k} B & \xrightarrow{k_\ast} \text{Fun}(X, A) & \xrightarrow{k_\ast} \text{Fun}(X, B)
\end{array}$$

defines a cartesian functor in an $\infty$-cosmos $\mathcal{K}$ if and only if for all $X \in \mathcal{K}$, the square displayed above right defines a cartesian functor between cartesian fibrations of quasi-categories.

\(^{11}\)A strict adjunction morphism is given by a pair of functors, the horizontals of (5.5.2), that define strictly commutative squares with both the left and with the right adjoints and so that the units of each adjunction whisker along these functors to each other and the counits of each adjunction whisker along these functors to each other. See Proposition B.6.2 for more.
Proof. Exercise 5.5.i.

Our aim is now to characterize those 1-arrows in $\text{Fun}(X, E)$ that represent $p$-cartesian natural transformation for some cartesian fibration $p : E \rightarrow B$. Recall that the 1-arrows in $\text{Fun}(X, E)$ are in bijection with the 0-arrows of $\text{Fun}(X, E^2) \cong \text{Fun}(X, E)^2$.

5.5.4. Definition ($p$-cartesian 1-arrow). Let $p : E \rightarrow B$ be a cartesian fibration and consider a 1-arrow $\psi : e' \rightarrow e$ in $\text{Fun}(X, E)$, defining an element $\psi : 1 \rightarrow \text{Fun}(X, E^2) \cong \text{Fun}(X, E)^2$. Say $\psi$ is a $p$-cartesian 1-arrow if it is isomorphic to some element in the image of the right adjoint right inverse functor

$$\text{Fun}(X, \text{Hom}_B(B, p)) \overset{\chi^*}{\longrightarrow} \text{Fun}(X, E^2)$$

of Theorem 5.2.10(iii).

The new notion of $p$-cartesian 1-arrow coincides exactly with the previous notion of $p$-cartesian natural transformation:

5.5.5. Lemma. Consider a cartesian fibration $p : E \rightarrow B$ between $\infty$-categories. For a 1-arrow $\psi : e' \rightarrow e$ in $\text{Fun}(X, E)$, the following are equivalent:

(i) $\psi$ is a $p$-cartesian 1-arrow.

(ii) $\psi$ represents a $p$-cartesian natural transformation $X \xleftarrow{e'} \xrightarrow{\psi} E$.

(iii) $\psi$ represents a natural transformation

$$\begin{array}{ccc}
1 & \xrightarrow{\eta} & \text{Fun}(X, E) \\
\psi & \xleftarrow{\eta} & e
\end{array}$$

that is cartesian for $p : \text{Fun}(X, E) \rightarrow \text{Fun}(X, B)$.

Conversely, a natural transformation $X \xleftarrow{e'} \xrightarrow{\psi} E$ is $p$-cartesian if and only if any representing 1-arrow $r^* \psi : X \rightarrow E^2$ satisfies all of these equivalent conditions.

Proof. We start with the final clause. Note from Exercise 3.2.i that homotopic 1-arrows are isomorphic as objects of $\text{Fun}(X, E^2)$ so if some 1-arrow representing a $p$-cartesian transformation is a $p$-cartesian 1-arrow then all representatives of that natural transformation are.

Now the equivalence (i)$\iff$(ii) follows from Theorem 5.2.10(iv)$\iff$(vi) once we establish that a 1-arrow of $\text{Fun}(X, E)$, when encoded as a functor $r^* \psi : X \rightarrow E^2$ is in the essential image of $r^* \chi^*$ if and only if the component $\eta^* \psi^*$ of the unit of $r^* p^* \xrightarrow{\sim} r^* \chi^*$ is invertible.

If $\psi : e' \rightarrow e$ is a $p$-cartesian 1-arrow, then by definition there exists some $r^* \beta : X \rightarrow \text{Hom}_B(B, p)$ and an invertible 2-cell

$$\begin{array}{ccc}
X & \xrightarrow{r^* \beta} & \text{Hom}_B(B, p) \\
\xleftarrow{r^* \psi} & \equiv & \xrightarrow{r^* \chi} E^2
\end{array}$$
The unit $\eta$ of the adjunction $\eta^e : \Psi^e \to \Psi$ of Theorem 5.2.10(iii) has the property that $\eta^e \chi^e$ is invertible, so the component $\eta^e \chi X^e \beta$ is invertible and so $\eta^e \psi^e$ is also invertible. By Theorem 5.2.10(vi)$\Rightarrow$(iv), this implies that $\psi$ represents a $p$-cartesian natural transformation.

Conversely, if $\psi$ defines a $p$-cartesian natural transformation then Theorem 5.2.10(vi) tells us that for any representing 1-arrow $\eta^e : X \to E$, the component $\eta^e \psi^e$ is an isomorphism, which proves that $\eta^e \psi^e$ is in the essential image of $\chi^e$ and thus defines a $p$-cartesian 1-arrow.

Finally, via the characterization of cartesian transformations given in Theorem 5.2.10(vi) and the fact that the adjunction $\eta^e \chi^e : \Psi^e \to \Psi$ in the homotopy 2-category $\mathcal{K}$ of an $\infty$-cosmos $\mathcal{K}$ induces an adjunction $\eta^e \chi^e : \Psi^e \to \Psi^e$ in $\mathcal{QCat}$, the conditions (ii) and (iii) are tautologically equivalent. The former refers to the adjunction between categories $hFun(X, E)$ and $hFun(X, B)$, while the latter refers to the adjunction between categories $hFun(\mathbf{1}, \text{Fun}(X, E))$ and $hFun(\mathbf{1}, \text{Fun}(X, B))$ and these are isomorphic. □

Combining Lemma 5.5.5 with Proposition 5.5.1 we arrive at a new equivalent definition of cartesian fibrations.

5.5.6. **Corollary.** An isofibration $p : E \to B$ is a cartesian fibration if and only if

(i) Any 1-arrow with codomain $B$ admits a $p$-cartesian lift with specified codomain 0-arrow.

(ii) $p$-cartesian 1-arrows are stable under precomposition with 0-arrows. □

5.5.7. **Lemma.** Let $p : E \to B$ be a cartesian fibration and consider a 2-arrow

\[
\begin{array}{ccc}
\psi' & \rightarrow & \psi \\
\downarrow & & \downarrow \\
\psi'' & \rightarrow & \psi
\end{array}
\]

in $\text{Fun}(X, E)$.

(i) If $\psi$ and $\psi'$ are $p$-cartesian 1-arrows, so is $\psi''$.

(ii) If $\psi$ and $\psi''$ are $p$-cartesian 1-arrows, so is $\psi'$.

(iii) If $\psi$ and $\psi''$ are $p$-cartesian 1-arrows and $p\psi'$ is invertible, then $\psi'$ is invertible.

**Proof.** Via Lemma 5.5.5, (i) and (ii) are Lemmas 5.1.7(i) and (ii), while (iii) is Lemma 5.1.10. □

5.5.8. **Lemma.** A 2-cell as below left

\[
\begin{array}{ccc}
Q & \xrightarrow{e'} & \text{Fun}(X, E) \\
\psi & \xrightarrow{q} & \\
\xrightarrow{e} & & \\
\end{array}
\]

\[
\begin{array}{ccc}
Q & \xleftarrow{e'} & \text{Fun}(X, E) \\
\psi & \xleftarrow{q} & \\
\xleftarrow{e} & & \\
\end{array}
\]

\[
\begin{array}{ccc}
X & \xrightarrow{e'q} & E \\
\psi q & \xrightarrow{e'} & \\
\xrightarrow{e} & & \\
\end{array}
\]

is $p_*$-cartesian if and only if each of its components $\psi q$ is $p$-cartesian.

**Proof.** If $\psi$ is $p_*$-cartesian, then so is the restriction $\psi q$ along any element $q : \mathbf{1} \to Q$. By Lemma 5.5.5 this tells us that $\psi q$ defines a $p$-cartesian transformation.

Conversely, if $\psi q$ is a $p$-cartesian transformation, then Lemma 5.5.5 tells us that $\psi q$ is a $p_*$-cartesian transformation. Now consider the factorization $\psi = \chi \cdot \zeta$ through $p_*$-cartesian lift $\chi$ of $p_* \psi$. Because the components $\psi q$ of $\psi$ are $p_*$-cartesian, the components $\zeta q$ of $\zeta$ are isomorphisms. By Corollary 1.1.21, an arrow in an exponential quasi-category $\text{Fun}(X, E)^Q$ is an isomorphism if and only if it is a pointwise isomorphism, so this implies that $\psi$ is an isomorphism. By isomorphism stability of cartesian transformations, we thus conclude that $\psi$ is $p_*$-cartesian. □
5.5.1. **EXERCISE.** Prove Corollary 5.5.3.

### 5.6. Discrete Cartesian Fibrations

Cartesian and cocartesian fibrations encode families of ∞-categories acted upon contravariantly or covariantly by the base ∞-category. In certain special cases, the ∞-categories arising as fibers of a cartesian or cocartesian fibration are all discrete, in the sense studied in §1.2. As the analogous functors between 1-categories are called discrete fibrations or discrete opfibrations, we refer to these maps of ∞-categories as “discrete cartesian fibrations” or “discrete cocartesian fibrations,” respectively. Our aim in this section is to study this special class of fibrations.

Before giving the definition, we describe the appropriate sort of “discreteness” required of an isofibration $p: E \to B$. Recall from Definition 1.2.26 that an object $E$ in an ∞-cosmos $\mathcal{K}$ is discrete if for all $X \in \mathcal{K}$, the functor space $\text{Fun}(X, E)$ is a Kan complex. Since, by Corollary 1.1.15, a quasi-category is a Kan complex just when its homotopy category is a groupoid, an ∞-category $E$ is discrete if and only if every natural transformation with codomain $E$ is invertible.

Discrete fibrations will be isofibrations $p: E \to B$ in an ∞-cosmos $\mathcal{K}$ that are discrete when considered as an object of the sliced ∞-cosmos $\mathcal{K}/B$; we call such maps discrete isofibrations for short. Using Proposition 3.6.2, there are several equivalent ways to unpack the notion of discrete object in $\mathcal{K}/B$ at the level of the homotopy 2-category $\mathcal{H}\mathcal{K}$:

**5.6.1. Lemma.** An isofibration $p: E \to B$ in an ∞-cosmos $\mathcal{K}$ is discrete as an object of $\mathcal{K}/B$ if and only if either of the equivalent conditions hold:

(i) Any $X \xrightarrow{a} E$ for which $p\gamma$ is an identity is invertible.

(ii) Any $X \xrightarrow{a} E$ for which $p\gamma$ is an isomorphism is invertible.

**Proof.** Exercise 5.6.i. □

Thus, the discrete isofibrations are exactly those isofibrations that define conservative functors in the homotopy 2-category $\mathcal{H}\mathcal{K}$. Neither the domain or codomain of a discrete isofibration need be discrete ∞-categories; see Exercise 5.6.ii. Instead, the discreteness in the sliced ∞-cosmos is “fiberwise”:

**5.6.2. Lemma.** The fibers of a discrete isofibration are discrete ∞-categories.

**Proof.** Recall from Lemma 1.2.27 that discrete ∞-categories can be characterized internally to an ∞-cosmos in a way that makes it clear that discreteness is preserved by cosmological functors. In particular, the pullback functor $b^*: \mathcal{K}/B \to \mathcal{K}$ associated to an element $b: 1 \to B$, preserve discrete objects. Hence, the fibers of a discrete isofibration $p: E \to B$ are discrete ∞-categories. □

The converse to Lemma 5.6.2 holds in ∞-cosmoi of (∞, 1)-categories, as we discover in Proposition 12.2.3: in such contexts, an isofibration $p: E \to B$ is discrete if and only if its fibers are discrete ∞-categories. Thus, in such ∞-cosmoi, the discrete cartesian fibrations and discrete cocartesian fibrations we presently introduce can be thought of as “∞-groupoid-valued pseudofunctors.”
5.6.3. Definition (discrete co/cartesian fibration). An isofibration \( p: E \to B \) in an \( \infty \)-cosmos \( \mathcal{K} \) is a **discrete cartesian fibration** if it is a cartesian fibration that is discrete as an object of \( \mathcal{K}_B \). Dually, \( p \) is a **discrete cocartesian fibration** if it is a cocartesian fibration that is discrete as an object of \( \mathcal{K}_B \).

5.6.4. Digression (right and left fibrations of quasi-categories). In the \( \infty \)-cosmos of quasi-categories, the discrete cartesian fibrations coincide with Joyal’s class of **right fibrations**—those maps that lift against the right horn inclusions—and dually the discrete cocartesian fibrations coincide with Joyal’s class of **left fibrations**; see Proposition F.4.12. While the terminology of left/right fibrations is more familiar in the \( \infty \)-categorical literature, we use the terms “discrete co/cartesian fibrations” to clarify the relationship between these classes of maps and their non-discrete and 1-categorical analogues.

As in §5.4, the theory of discrete cocartesian fibrations can be obtained by interpreting results about discrete cartesian fibrations in the co-dual \( \infty \)-cosmos. Thus, we streamline our exposition by focusing primarily on the class of discrete cartesian fibrations.

There is also a direct 2-categorical characterization of the discrete cartesian fibrations, as those maps \( p: E \to B \) with the property that every 2-cell \( \beta: b \Rightarrow pe \) has an essentially unique lift with codomain \( e \). This is closely related to the observation that for a discrete cartesian or cocartesian fibration \( p \), there are no special classes of \( p \)-cartesian or \( p \)-cocartesian cells, unlike the case for the indiscrete analogues.

5.6.5. Proposition.

(i) If \( p: E \to B \) is a discrete cartesian fibration, every natural transformation with codomain \( E \) is \( p \)-cartesian.

(ii) An isofibration \( p: E \to B \) is a discrete cartesian fibration if and only if every 2-cell \( \beta: b \Rightarrow pe \) has an essentially unique lift: given \( \chi: e' \Rightarrow e \) and \( \psi: e'' \Rightarrow e \) so that \( p\chi = p\psi = \beta \), then there exists an isomorphism \( \gamma: e'' \Rightarrow e' \) with \( \chi \cdot \gamma = \psi \) and \( p\gamma = \text{id} \).

**Proof.** By Proposition 5.1.11, if \( p: E \to B \) is a cartesian fibration, then any natural transformation \( \psi \) with codomain \( E \) factors through a \( p \)-cartesian lift of \( p\psi \) via a natural transformation \( \gamma \) so that \( p\gamma = \text{id} \). When \( p \) is discrete, this \( \gamma \) is an isomorphism, and thus \( \psi \) is isomorphic to a \( p \)-cartesian transformation, and thus is itself \( p \)-cartesian by Lemma 5.1.9.

From what we have just observed in (i) and the essential uniqueness of \( p \)-cartesian lifts in Lemma 5.1.8, we see that if \( p: E \to B \) is a discrete cartesian fibration, then any natural transformation \( \beta: b \Rightarrow pe \) has an essentially unique lift. For the converse, note that any \( p: E \to B \) satisfying the hypothesis of (ii) is a discrete isofibration: if \( \psi: e' \Rightarrow e \) is so that \( p\psi = \text{id} \), then \( \text{id}: e \Rightarrow e \) is another lift of \( p\psi \) and essential uniqueness provides an inverse isomorphism \( \psi^{-1}: e \Rightarrow e' \).

To complete the proof, it remains to show that any \( p: E \to B \) satisfying the hypothesis of (ii) is a cartesian fibration. We do this by establishing the 2-categorical characterization of Proposition 5.2.18, showing that any 2-cell \( \psi: e' \Rightarrow e \) with codomain \( E \) is weakly \( p \)-cartesian—and hence, by Proposition 5.2.18 again, \( p \)-cartesian in the usual sense.

To that end consider a pair \( \tau: e'' \Rightarrow e \) and \( \gamma: pe'' \Rightarrow pe \) so that \( p\tau = p\psi \cdot \gamma \). By the hypothesis that every 2-cell admits an essentially unique lift, we can construct a lift \( \mu: \tilde{e} \Rightarrow e' \) so that \( p\mu = \gamma \).

Now \( \tau \) and \( \psi \cdot \mu \) are two lifts of \( p\tau \) with the same codomain, so there exists an isomorphism \( \zeta: e'' \Rightarrow \tilde{e} \) with \( p\zeta = \text{id} \). The composite \( \mu \cdot \zeta \) then defines the desired lift of \( \gamma \) to a cell so that \( \tau = \chi \cdot \mu \cdot \zeta \). \(\square\)

As an immediate consequence of (i):
5.6.6. **Corollary.** Any commutative square

\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
q \downarrow & & \downarrow p \\
A & \xrightarrow{k} & B
\end{array}
\]

from a cartesian fibration \(q\) to a discrete cartesian fibration \(p\) defines a cartesian functor. \(\square\)

5.6.7. **Lemma** (pullback stability). In any pullback square

\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
q \downarrow & \downarrow a & \downarrow p \\
A & \xrightarrow{k} & B
\end{array}
\]

if \(p\) is a discrete cartesian fibration then \(q\) is a discrete cartesian fibration.

**Proof.** In light of Proposition 5.2.4 it remains only to verify that \(q\) is discrete. Consider a 2-cell

\[
\begin{array}{c}
X \xrightarrow{a} \xleftarrow{b} F
\end{array}
\]

so that \(q \gamma\) is invertible. Then \(k q \gamma = p h \gamma\) is invertible and conservativity of \(p\) implies that \(h \gamma\) is invertible.

By Lemma 3.1.5, the pullback square of functor spaces

\[
\begin{array}{ccc}
\text{Fun}(X,F) & \xrightarrow{h_*} & \text{Fun}(X,E) \\
q_* \downarrow & & \downarrow p_* \\
\text{Fun}(X,A) & \xrightarrow{k_*} & \text{Fun}(X,B)
\end{array}
\]

induces a smothering functor

\[\text{hFun}(X,F) \rightarrow \text{hFun}(X,E) \times_{\text{hFun}(X,B)} \text{hFun}(X,A)\]

We’ve just verified that the image of \(\gamma\) is an isomorphism, so conservativity implies that \(\gamma\) is also invertible. \(\square\)

In analogy with Theorem 5.2.10, there is an internal characterization of discrete cartesian fibrations, which in the discrete case takes a much simpler form.

5.6.8. **Proposition** (internal characterization of discrete fibrations). An isofibration \(p: E \rightarrow B\) is a discrete cartesian fibration if and only if the functor \(\text{r}p \kappa^* : E^2 \rightarrow \text{Hom}_B(B,p)\) is an equivalence and a discrete cocartesian fibration if and only if the functor \(\text{r}p \kappa^* : E^2 \rightarrow \text{Hom}_B(p,B)\) is an equivalence.

Recall from Theorem 5.2.10(iii) that an isofibration \(p: E \rightarrow B\) defines a cartesian fibration if and only if \(\text{r}p \kappa^* : E^2 \rightarrow \text{Hom}_B(B,p)\) admits a right adjoint right inverse. Proposition 5.6.8 asserts that \(p\) defines a discrete cartesian fibration if and only if the unit of that adjunction, a natural transformation that defines the factorization of any natural transformation with codomain \(E\) through the canonical \(p\)-cartesian lift of its image under \(p\), is an isomorphism, in which case that adjunction defines an adjoint equivalence and all natural transformations with codomain \(E\) are \(p\)-cartesian.
Proof. Assume first that $p : E \to B$ is a discrete cartesian fibration. By Theorem 5.2.10(iii), \( p^* : E^2 \to \operatorname{Hom}_B(B, p) \) then admits a right adjoint $\gamma p^*$ with invertible counit $\epsilon : \gamma p^* \gamma^* \cong \id$. We will show that in this case the unit $\eta : \id \Rightarrow \gamma^* p^*$ is also invertible, proving that $\gamma p^* \dashv \gamma^*$ defines an adjoint equivalence.

Since the counit of $\gamma p^* \dashv \gamma^*$ is invertible, $\gamma p^* \eta$ is an isomorphism. Thus $p_1 \gamma p^* \eta = p_1 \eta$ and $p_0 \gamma p^* \eta = pp_0 \eta$ are both isomorphisms. By conservativity of the discrete fibration $p : E \to B$ proven in Lemma 5.6.1, this implies that $p_0 \eta$ is invertible and now 2-cell conservativity for $E^2$ reveals that $\eta$ is an isomorphism.

Conversely, if $\gamma p^* : E^2 \to \operatorname{Hom}_B(B, p)$ is an equivalence, by Proposition 2.1.12, we may choose a right adjoint equivalence inverse. The counit of this adjoint equivalence is necessarily an isomorphism, so by Theorem 5.2.10(iii) we know that $p : E \to B$ is a cartesian fibration. Since the unit of this adjoint equivalence is also an isomorphism, Theorem 5.3.4(vi) tells us that every natural transformation with codomain $E$ is $p$-cartesian, and now the conservativity property for cartesian transformations of Lemma 5.1.9 tells us that $p : E \to B$ defines a conservative functor, and in particular is discrete. □

Since equivalences and simplicial limits in an $\infty$-cosmos are representably-defined notions, it follows immediately from Proposition 5.6.8 that:

5.6.9. Proposition. An isofibration $p : E \to B$ in an $\infty$-cosmos $\mathcal{K}$ defines a discrete cartesian fibration if and only if for all $X \in \mathcal{K}$, the functor $p_* : \operatorname{Fun}(X, E) \to \operatorname{Fun}(X, B)$ defines a discrete cartesian fibration of quasi-categories. □

Using the internal characterization, it is straightforward to verify that discrete cartesian fibrations compose and cancel on the left:

5.6.10. Lemma.

(i) If $p : E \to B$ and $q : B \to A$ are discrete cartesian fibrations, so is $qp : E \to A$.

(ii) If $p : E \to B$ is an isofibration and $q : B \to A$ and $qp : E \to A$ are discrete cartesian fibrations, then so is $p : E \to B$.

Proof. By considering the defining pullback diagrams for the Leibniz cotensors of Remark 5.2.12, the map $E^2 \to \operatorname{Hom}_A(A, qp)$ that tests whether $qp : E \to A$ is a discrete cartesian fibration factors as the map $E^2 \to \operatorname{Hom}_B(B, p)$ that tests whether $p : E \to B$ is a discrete cartesian fibration followed by a pullback of the map $B^2 \to \operatorname{Hom}_A(A, q)$ that tests whether $q : B \to A$ is a discrete cartesian fibration:

\[
\begin{array}{ccc}
E^2 & \xrightarrow{p^*} & \operatorname{Hom}_B(B, p) \\
\downarrow & & \downarrow \\
E & \xrightarrow{p} & B \\
\downarrow & & \downarrow \\
\operatorname{Hom}_A(A, qp) & \xrightarrow{p^*} & \operatorname{Hom}_A(A, q) \\
\downarrow & & \downarrow \\
\operatorname{Hom}_A(A, q) & \xrightarrow{p^*} & \operatorname{Hom}_A(A, q) \\
\end{array}
\] (5.6.11)

Both parts now follow from Proposition 3.3.3 and the 2-of-3 property for equivalences. □

5.6.12. Lemma. Suppose $q : B \to A$ is a discrete cartesian fibration.

183
(i) An isofibration \( p : E \to B \) is a cartesian fibration if and only if \( qp : E \to A \) is a cartesian fibration, in which case \( p \)-cartesian transformations coincide with \( sp \)-cartesian transformations.

(ii) A commutative square \((h, q)\) as below-left defines a cartesian functor between cartesian fibrations \( p : E \to B \) and \( r : F \to A \) if and only if \( h \) defines a cartesian functor from \( qp \) to \( r \).

\[
\begin{array}{ccc}
E & \xrightarrow{h} & F \\
p \downarrow & & \downarrow r \\
B & \xrightarrow{q} & A
\end{array}
\]

Proof. For (i), Proposition 5.6.8 tells us that if \( q \) is a discrete cartesian fibration, then the map \( \rightharpoonup q\kappa : B^2 \to \text{Hom}_A(A, q) \) is an equivalence. In the diagram (5.6.11) we see that this map pulls back to define an equivalence between \( \rightharpoonup p\kappa : E^2 \to \text{Hom}_B(B, p) \) and \( \rightharpoonup qp\kappa : E^2 \to \text{Hom}_A(A, qp) \). Thus by Proposition 2.1.13, if either of these functors admits a right adjoint right inverse, then both do. Hence, by Theorem 5.2.10(iii), \( p \) is a cartesian fibration if and only if \( qp \) is a cartesian fibration.

When these conditions hold, Lemma 5.2.3 tells us that a natural transformation \( \psi \) with codomain \( E \) is \( qp \)-cartesian if and only if it is \( p \)-cartesian and if \( p\psi \) is \( q \)-cartesian. Since all natural transformations with codomain \( B \) are \( q \)-cartesian, the second part of the statement follows.

Now (ii) follows directly from the definition of cartesian functor and the observation that \( p \)-cartesian transformations coincide with \( qp \)-cartesian transformations. \( ^{12} \)

The internal characterization of discrete cartesian fibrations is useful for establishing a general family of examples:

5.6.13. Lemma. A trivial fibration \( p : E \Rightarrow B \) is a discrete bifibration.

Proof. By Remark 5.2.12, the canonical functors \( \rightharpoonup p\kappa : E^2 \to \text{Hom}_B(B, p) \) and \( \rightharpoonup p\kappa : E^2 \to \text{Hom}_B(p, B) \) can be constructed as the Leibniz cotensor of the monomorphism \( 1 : 1 \hookrightarrow 2 \) in the first case and \( 0 : 1 \to 2 \) in the second with the trivial fibration \( p : E \Rightarrow B \). By Lemma 1.2.14, both maps are trivial fibrations and in particular equivalences. Now Proposition 5.6.8 proves that \( p \) is a discrete cartesian fibration and also a discrete cocartesian fibration. \( \Box \)

We have not yet met the most significant family of examples of discrete cartesian fibrations. Proposition 5.2.16 proves that for any \( \infty \)-category \( A \) in an \( \infty \)-cosmos \( \mathcal{K} \), the domain-projection functor \( p_0 : A^2 \to A \) defines a cartesian fibration. Unless \( A \) is discrete, this functor does not define a discrete cartesian fibration in the \( \infty \)-cosmos \( \mathcal{K} \), see Exercise 5.6.ii. However, recall that \( p_0 \)-cartesian lifts can be constructed to project to identity arrows along \( p_1 : A^2 \to A \). This suggests that we might productively consider the domain-projection functor as a map over \( A \), in which case we have the following result:

5.6.14. Proposition. For any \( \infty \)-category \( A \) in an \( \infty \)-cosmos \( \mathcal{K} \)

\[
\begin{array}{ccc}
A^2 & \xrightarrow{(p_1, p_0)} & A \times A \\
p_1 \downarrow & & \downarrow \pi \\
A & \xrightarrow{\pi} & A
\end{array}
\]

defines a discrete cartesian fibration in the sliced \( \infty \)-cosmos \( \mathcal{K}_{/A} \).

\(^{12}\) If \( q \) is a cartesian fibration but not discrete, then if the left-hand diagram defines a cartesian functor, then so does the right one, but the converse no longer holds.
Proof. By 2-cell conservativity, (5.6.15) is a discrete object in the sliced ∞-cosmos 
\((\mathcal{K}/A)_{/\pi} : A \times A \to A \cong \mathcal{K}_{/A \times A}\).

So it remains only to prove that this functor defines a cartesian fibration. We prove this using Theorem 5.2.10(ii). The first step is to compute the right representable comma object for the functor (5.6.15) by interpreting the formula (3.4.2) in the sliced ∞-cosmos \(\mathcal{K}/A\). By Proposition 1.2.22, the 2-cotensor of the object \(\pi : A \times A \to A\) is \(\pi : A \times A \twoheadrightarrow A\), and this right representable comma is computed by the left-hand pullback in \(\mathcal{K}_{/A}\) below:

\[
\begin{array}{ccc}
\text{Hom}_A(A, p_0) & \to & A \times A^2 \\
\downarrow & & \downarrow \pi \\
A^2 & \to & A \times A \\
\downarrow & \nearrow \pi & \\
A & & \\
\end{array}
\]

Pasting with the right-hand pullback in \(\mathcal{K}\), we recognize that the ∞-category so-constructed coincides with the right representable comma object for the functor \(p_0 : A^2 \to A\) considered as a map in \(\mathcal{K}\). Under the equivalence \(\text{Hom}_A(A, p_0) \cong A^3\) established in the proof of Proposition 5.2.16, the isofibration \(p_2 : \text{Hom}_A(A, p_0) \to A\) is evaluation at the final element \(2 \in \mathfrak{3}\) in the composable pair of arrows. Similarly, the canonical functor \(\text{id}_{p_0} : A^2 \to \text{Hom}_A(A, p_0)\) induced by \(p_0\) in \(\mathcal{K}\) coincides with the canonical functor \(\text{id}_{(p_1, p_0)} : A^2 \to \text{Hom}_A(A, p_0)\) over \(A\) induced by \(p_1, p_0\) in \(\mathcal{K}_{/A}\).

Since \(p_0 : A^2 \to A\) is a cartesian fibration in \(\mathcal{K}\), Theorem 5.2.10(ii) tells us that the functor \(\text{id}_{p_0} : A^2 \to \text{Hom}_A(A, p_0) \cong A^3\) admits a right adjoint \(r\) over \(A\). The proofs of Theorem 5.2.10(iii)⇒(ii) and Proposition 5.2.16 combine to provide a construction: this adjunction can be defined by cotensoring the composite adjunction of categories below-left into \(A\):

\[
\begin{array}{ccc}
2 & \cong & \mathfrak{3} \\
\downarrow & & \downarrow \llcorner \\
2 \times 2 & \cong & A^2 \\
\downarrow & \nearrow \sigma^0 & \\
(1,0) & & (2,0) \\
\downarrow & \nearrow k & \\
\mathfrak{2} & \cong & \mathfrak{3} \\
\end{array}
\]

where \(\ell \dashv k\) is described in the proof of Proposition 5.2.16. The composite right adjoint is the functor \(\sigma^0 : \mathfrak{3} \to \mathfrak{2}\) that sends 0 and 1 to 0 and 2 to 1, while the composite left adjoint is the functor \(\delta^1 : \mathfrak{2} \to \mathfrak{3}\) that sends 0 to 0 and 1 to 2. In particular, this adjunction lies in the strict slice 2-category under the inclusion of the “endpoints” of \(\mathfrak{2}\) and \(\mathfrak{3}\).

It follows that upon cotensoring into \(A\), we obtain a fibered adjunction over \(A \times A\), which by Theorem 5.2.10(ii) implies that (5.6.15) is a cartesian fibration in \(\mathcal{K}_{/A}\), completing the proof. □

Combining Propositions 5.2.16 and Proposition 5.6.14, we can now generalize both results to arbitrary comma ∞-categories.

5.6.16. Corollary. For any functors \(C \xrightarrow{g} A \xleftarrow{f} B\) between ∞-categories in an ∞-cosmos \(\mathcal{K}\):
(i) The domain-projection functor $p_0 : \text{Hom}_A(f, g) \to B$ is a cartesian fibration. Moreover, a natural transformation $\psi$ with codomain $\text{Hom}_A(f, g)$ is $p_0$-cartesian if and only if $p_1 \psi$ is invertible.

(ii) The codomain-projection functor $p_1 : \text{Hom}_A(f, g) \to C$ is a cocartesian fibration. Moreover, a natural transformation $\psi$ with codomain $\text{Hom}_A(f, g)$ is $p_1$-cartesian if and only if $p_0 \psi$ is invertible.

(iii) The functor

$$
\begin{array}{ccc}
\text{Hom}_A(f, g) & \xrightarrow{(p_1, p_0)} & C \times B \\
\downarrow p_1 & & \downarrow \pi \\
C & &
\end{array}
$$

defines a discrete cartesian fibration in $\mathcal{K}_C$.

(iv) The functor

$$
\begin{array}{ccc}
\text{Hom}_A(f, g) & \xrightarrow{(p_1, p_0)} & C \times B \\
\downarrow p_0 & & \downarrow \pi \\
B & &
\end{array}
$$

defines a discrete cocartesian fibration in $\mathcal{K}_B$.

**Proof.** We prove (i) and (iii), starting with the latter, and leave the dualizations to the reader. Since $p_1 : \text{Hom}_A(A, g) \to C$ is the pullback of $p_1 : A^2 \to A$ along $g$, we may use the cosmological functor $g^* : \mathcal{K}_A \to \mathcal{K}_C$ to pull back the discrete cartesian fibration of Proposition 5.6.14 to a discrete cartesian fibration

$$
\begin{array}{ccc}
\text{Hom}_A(A, g) & \xrightarrow{(p_1, p_0)} & C \times A \\
\downarrow p_1 & & \downarrow \pi \\
C & &
\end{array}
$$
in $\mathcal{K}_C$. Now

$$
\begin{array}{ccc}
\text{Hom}_A(f, g) & \xrightarrow{(p_1, p_0)} & \text{Hom}_A(A, g) \\
\downarrow (p_1, p_0) & & \downarrow (p_1, p_0) \\
C \times B & \xrightarrow{C \times f} & C \times A \\
\downarrow \pi & & \downarrow \pi \\
C & &
\end{array}
$$
is a pullback square in $\mathcal{K}_C$, so Lemma 5.6.7 implies that the pullback is also a discrete cartesian fibration.

Using (iii) we can now prove (i). In fact we show more generally that if

$$
\begin{array}{ccc}
E & \xrightarrow{(q, p)} & C \times B \\
\downarrow q & & \downarrow \pi \\
C & &
\end{array}
$$
defines a cartesian fibration in \( \mathcal{K}/C \) then \( p: E \to B \) defines a cartesian fibration in \( \mathcal{K} \). By Theorem 5.2.10(ii), this functor defines a cartesian fibration in \( \mathcal{K}/C \) if and only if the functor \( \rho \text{id}_{(q,p)} = \rho \text{id}_{p} \)

\[
\begin{array}{c}
E \\
\downarrow \rho
\end{array}
\text{Hom}_B(B,p)
\begin{array}{c}
C \times B
\end{array}
\]

admits a right adjoint \( r \) over \( C \times B \). Composing with \( \pi: C \times B \to B \), this fibered adjunction defines an adjunction over \( B \). Applying Theorem 5.2.10(ii) in \( \mathcal{K} \) this time allows us to conclude that \( p: E \to B \) is a cartesian fibration.

Note that the domain projection \( p_0: \text{Hom}_A(f,A) \to B \) is the pullback of \( p_0: A^2 \to A \) along \( f: B \to A \), so Proposition 5.2.4 proves directly from Proposition 5.2.16 that this functor is a cartesian fibration, but \( p_0: \text{Hom}_A(A,g) \to A \) is not similarly a pullback of \( p_0: A^2 \to A \). This is why a more circuitous argument to the general result is needed.

As a corollary, we can finally introduce one of the key examples of discrete cartesian fibrations:

5.6.17. COROLLARY (domain projection from an element). For an element \( b: 1 \to B \), the domain-projection functor \( p_0: \text{Hom}_B(B,b) \to B \) is a discrete cartesian fibration, and the codomain-projection functor \( p_1: \text{Hom}_B(b,B) \to B \) is a discrete cocartesian fibration.

PROOF. By Corollary 5.6.16, \( p_0: \text{Hom}_B(B,b) \to B \) is a cartesian fibration and \( p_1: \text{Hom}_B(b,B) \to B \) is a cocartesian fibration. Discreteness in each case follows immediately from 2-cell conservativity. If

\[
\begin{array}{c}
X \\
\downarrow \gamma
\end{array}
\text{Hom}_B(B,b)
\begin{array}{c}
\text{Hom}_B(B,b)
\end{array}
\]

is a natural transformation for which \( p_0 \gamma \) is an identity, then since \( p_1 \gamma \) is also an identity, this being a 2-cell whose codomain is the terminal \( \infty \)-category, \( \gamma \) must be invertible.

Exercises.

5.6.i. EXERCISE. Prove Lemma 5.6.1.

5.6.ii. EXERCISE.

(i) Prove that \( p_0: A^2 \to A \) is a discrete isofibration if and only if \( A \) is a discrete \( \infty \)-category.

(ii) Corollary 5.6.17 proves that for any element \( a: 1 \to A \), \( p_0: \text{Hom}_A(A,a) \to A \) is a discrete cartesian fibration. Is \( \text{Hom}_A(A,a) \) necessarily a discrete \( \infty \)-category?

5.6.iii. EXERCISE. Use Theorem 5.3.4 to give an alternate proof of Corollary 5.6.6.

5.7. The Yoneda Lemma

Let \( b: 1 \to B \) be an element of an \( \infty \)-category \( B \) and consider its right representation \( \text{Hom}_B(B,b) \) as a comma \( \infty \)-category. In this case, there is no additional information carried by the codomain-projection functor, but Corollary 5.6.17 expresses a special property of the domain-projection functor \( p_0: \text{Hom}_B(B,b) \to B \): it defines a discrete cartesian fibration. The fibers of this map over an element \( a: 1 \to B \) are the internal mapping spaces \( \text{Hom}_B(a,b) \) of Definition 3.4.9. In this way, the right
representation of the element $b$ encodes the contravariant functor represented by $b$, which is why we have been referring to the comma $\infty$-categories $\text{Hom}_B(B, b)$ as “representable” all along.

Our aim in this section is to state and prove the Yoneda lemma in this setting, where contravariant representable functors are encoded as discrete cartesian fibrations. A dual statement applies to covariant representable functors encoded as discrete cocartesian fibrations $p_1 : \text{Hom}_B(b, B) \to B$. Informally, the Yoneda lemma asserts that “evaluation at the identity defines an equivalence,” so the first step towards the statement of the Yoneda lemma is to introduce this identity element, which in fact is something we’ve already encountered.

The identity arrow $\text{id}_b$ induces an element $\lceil \text{id}_b \rceil : 1 \to \text{Hom}_B(B, b)$ which Corollary 3.5.10 proves is terminal in the $\infty$-category $\text{Hom}_B(B, b)$ of arrows in $B$ with codomain $b$. The identity element inclusion defines a functor over $B$

$$
\begin{array}{c}
1 \\
\downarrow b \\
\text{Hom}_B(B, b)
\end{array} \\
\begin{array}{c}
B
\end{array}
\begin{array}{c}
p_0
\end{array}
\begin{array}{c}
p_1
\end{array}
$$

(5.7.1)

Technically, this functor does not live in the sliced $\infty$-cosmos $\mathcal{K}_B$ because the domain object $b : 1 \to B$ is not an isofibration but nevertheless for any isofibration $p : E \to B$, restriction along $\lceil \text{id}_b \rceil$ induces a functor between sliced quasi-categorical functor spaces

$$
\text{Fun}_B(\text{Hom}_B(B, b)) \xrightarrow{p_0} \text{Fun}_B(1, E^b) \\
\xrightarrow{\text{ev}_{\text{id}_b}} \text{Fun}_B(B, E) \xrightarrow{p_*} \text{Fun}_B(1, E)
$$

(5.7.2)

Here the codomain is the quasi-category defined by the pullback

$$
\begin{array}{c}
\text{Fun}_B(b, p)
\end{array} \\
\downarrow a \\
\begin{array}{c}
\text{Fun}_B(B, E)
\end{array} \\
\downarrow p_* \\
\begin{array}{c}
\text{Fun}(1, B)
\end{array}
$$

which is isomorphic to $\text{Fun}(1, E_b)$, the underlying quasi-category of the fiber $E_b$ of $p : E \to B$ over $b$. When $p : E \to B$ is a discrete isofibration, $\text{Fun}(1, E_b)$ is a Kan complex, and might be referred to more evocatively as the “underlying space” of the fiber $E_b$.

If a discrete cartesian fibration over $B$ is thought of as a $B$-indexed discrete $\infty$-category valued contravariant pseudofunctor, then maps of discrete cartesian fibrations over $B$ are “natural transformations”: the “naturality in $B$” arises because we only allow functors over $B$. This leads to our first statement of the fibrational Yoneda lemma:

5.7.3. THEOREM (discrete Yoneda lemma). If $p : E \to B$ is a discrete cartesian fibration, then

$$
\text{Fun}_B(\text{Hom}_B(B, b)) \xrightarrow{p_0} \text{Fun}_B(B, E) \xrightarrow{\text{ev}_{\text{id}_b}} \text{Fun}_B(1, E_b)
$$

is an equivalence of Kan complexes.

We will deduce this result from a “dependent” generalization where the target discrete cartesian fibration has codomain $\text{Hom}_B(B, b)$. In this case, the result provides an equivalence between sections of a discrete cartesian fibration and elements of the fiber over $\lceil \text{id}_b \rceil$. This result is analogous to the “path induction” principle for identity types in homotopy type theory: the inverse equivalence of Theorem 5.7.4 provides a “directed” version of the “transport” operation [101, §9].
5.7.4. Theorem (dependent Yoneda lemma). If \( b: 1 \to B \) is an element of an \( \infty \)-category \( B \) and \( q: F \to \text{Hom}_B(B, b) \) is a discrete fibration, then

\[
\text{Fun}_{\text{Hom}_B(B, b)}(\text{Hom}_B(B, b), F) \xrightarrow{\text{ev}_{\text{id}_b}} \text{Fun}(1, \text{F}_{\text{id}_b})
\]

is an equivalence of Kan complexes.

Theorem 5.7.3 is subsumed by a generalization that allows \( p: E \to B \) to be any cartesian fibration, not necessarily discrete. In this case, \( p \) encodes an \( \infty \)-category-valued contravariant \( B \)-indexed functor, as does \( p_0: \text{Hom}_B(B, b) \to B \). The correct notion of “natural transformation” between two such functors is now given by a cartesian functor over \( B \); see Exercise 5.3.iv. Given a pair of cartesian fibrations \( q: F \to B \) and \( p: E \to B \), we write

\[
\text{Fun}_{\text{cart}}(\text{Hom}_B(B, b) \xrightarrow{p_0} B, E \xrightarrow{p} B) \subset \text{Fun}_B(F \xrightarrow{q} B, E \xrightarrow{p} B)
\]

for the sub quasi-category containing all those simplices whose vertices define cartesian functors from \( q \) to \( p \).¹³

5.7.6. Theorem (Yoneda lemma). If \( p: E \to B \) is a cartesian fibration, then

\[
\text{Fun}_{\text{cart}}(\text{Hom}_B(B, b) \xrightarrow{p_0} B, E \xrightarrow{p} B) \xrightarrow{\text{ev}_{\text{id}_b}} \text{Fun}(1, E_b)
\]

is an equivalence of quasi-categories.

The proofs of these theorems overlap significantly and we develop them in parallel. The basic idea is to use the universal property of \( \text{ev}_{\text{id}_b} \) as a terminal element of \( \text{Hom}_B(B, b) \) in the \( \infty \)-cosmos \( \mathcal{K} \) to define a right adjoint to \( \text{ev}_{\text{id}_b} \) and prove that when \( p: E \to B \) is discrete or when the domain is restricted to the sub-quasi-category of cartesian functors, this adjunction defines an adjoint equivalence. Note that the functor \( \text{ev}_{\text{id}_b} \) is the image of the functor \( \text{id}_b \) under the 2-functor \( \text{Fun}_B(-, p): \text{h}(\mathcal{K}/B)^{op} \to \text{QCat} \). If the adjunction \( ! \dashv \text{ev}_{\text{id}_b} \) lived in the sliced \( \infty \)-cosmos \( \mathcal{K}/B \), this would directly construct a right adjoint to \( \text{ev}_{\text{id}_b} \). The main technical difficulty in following this outline is that the adjunction that witnesses the terminality of \( \text{id}_b \) does not live in the slice of the homotopy 2-category \( \text{h}\mathcal{K}/B \) but rather in a lax slice of the homotopy 2-category, that we now introduce.

5.7.7. Definition. Consider a 2-category \( \text{h}\mathcal{K} \) and an object \( B \in \text{h}\mathcal{K} \). The lax slice 2-category \( \text{h}\mathcal{K}/B \) is the strict 2-category whose

- objects are maps \( f: X \to B \) in \( \text{h}\mathcal{K} \) with codomain \( B \);
- 1-cells are diagrams

\[
\begin{array}{c}
X \xrightarrow{f} Y \\
\downarrow^s \downarrow^\approx \\
B \xrightarrow{g}
\end{array}
\]

in \( \text{h}\mathcal{K} \); and

¹³For any quasi-category \( Q \) and any subset of its vertices, there is a “full” sub-quasi-category containing exactly those vertices and all the simplices of \( Q \) that they span.
2-cells from the 1-cell displayed above to the 1-cell below-right are 2-cells \( \theta : t \Rightarrow t' \) so that

\[
\begin{array}{ccc}
X & \xrightarrow{t'} & Y \\
\downarrow t & \searrow \eta & \swarrow d \\
B & \downarrow g & B
\end{array}
= \begin{array}{ccc}
X & \xrightarrow{t'} & Y \\
f & \searrow \tau & \swarrow d \\
B & \downarrow g & B
\end{array}
\]

(5.7.9)

For instance, the adjunctions of Definition 2.2.1 that define terminal elements lift to the lax slice 2-category:

5.7.10. Lemma. Suppose \( a : 1 \to A \) defines a terminal element in an \( \infty \)-category \( A \) in an \( \infty \)-cosmos \( \mathcal{K} \). Then

\[
\begin{array}{ccc}
1 & \xrightarrow{a} & A \\
\eta & \searrow & \swarrow a \\
& A & \\
\end{array}
\]

is right adjoint to the unit map

\[
\begin{array}{ccc}
A & \xrightarrow{\eta} & 1 \\
\searrow \! & & \swarrow a \\
& A & \\
\end{array}
\]

in the lax slice 2-category \( \mathcal{K}_{//A} \).

Proof. We check that the unit and counit of the adjunction \( ! \dashv a \) that witnesses the terminality of \( a \) lift along the forgetful 2-functor \( \mathcal{K}_{//A} \to \mathcal{K} \), which amounts to verifying the condition (5.7.9). The forgetful 2-functor \( \mathcal{K}_{//A} \to \mathcal{K} \) is faithful on 1- and 2-cells, so the triangle equalities automatically hold for the lifted cells. These lax compatibility conditions reduce to the pasting equalities

\[
\begin{array}{ccc}
A & \xrightarrow{!} & 1 \\
\eta & \searrow & \swarrow a \\
& A & \\
\end{array}
\]

\[
\begin{array}{ccc}
A & \xrightarrow{1} & A \\
\eta & \searrow & \swarrow a \\
& A & \\
\end{array}
\]

\[
\begin{array}{ccc}
A & \xrightarrow{1} & 1 \\
\eta & \searrow & \swarrow a \\
& A & \\
\end{array}
\]

The first of these is trivial, while the second holds by the triangle equality \( \eta a = \text{id}_a \) of Lemma 2.2.2. □

Using somewhat non-standard 2-categorical techniques, we will transfer the adjunction of Lemma 5.7.10 to an adjoint equivalence

\[
\begin{array}{ccc}
\text{Fun}_A(A,F) & \xrightarrow{\sim} & \text{Fun}(1,F_a) \\
\downarrow \gamma & & \downarrow \gamma \\
\sim & & \sim
\end{array}
\]

between the Kan complex of sections of a discrete cartesian fibration \( q : F \to A \) and the underlying space of the fiber \( F_a \) over a terminal element \( a : 1 \to A \). Because our initial adjunction lives in the lax rather than the strict slice, the construction will be somewhat delicate, passing through a pair of auxiliary 2-categories that we now introduce.

5.7.11. Definition. Let \( \mathcal{K} \) be the homotopy 2-category of an \( \infty \)-cosmos and write \( \mathcal{K}^\circ \) for the strict 2-category whose

- objects are cospans

\[
A \xrightarrow{k} B \xleftarrow{p} E
\]

in which \( p \) is a cartesian fibration;
• 1-cells are diagrams of the form
\[
\begin{array}{ccc}
A' & \xrightarrow{k'} & B' \\
\downarrow a & & \downarrow e \\
A & \xleftarrow{k} & B \\
\end{array}
\] (5.7.12)

\[
\begin{array}{ccc}
A & \xrightarrow{\alpha} & \tilde{A} \\
\downarrow k & & \downarrow e \\
B & \xleftarrow{\beta} & \tilde{B} \\
\end{array}
\]

• and whose 2-cells consist of triples \(\alpha : a \Rightarrow \tilde{a}, \beta : b \Rightarrow \tilde{b}, \) and \(e : e \Rightarrow \tilde{e}\) between the verticals of parallel 1-cell diagrams so that \(pe = \beta p'\) and \(\tilde{\phi} \cdot k\alpha = \beta k' \cdot \phi.\)

5.7.13. Definition. Let \(\mathcal{K}\) be the homotopy 2-category of an \(\infty\)-cosmos and write \(\mathcal{K}^\circ\) for the strict 2-category whose

• objects are pullback squares
\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
\downarrow q & & \downarrow p \\
A & \xleftarrow{k} & B \\
\end{array}
\]
whose verticals are cartesian fibrations;

• 1-cells are cubes
\[
\begin{array}{ccc}
F' & \xrightarrow{h'} & E' \\
\downarrow q' & & \downarrow p' \\
A' & \xleftarrow{k'} & B' \\
\end{array}
\]
whose vertical faces commute and in which \(\chi : h\ell \Rightarrow eh'\) is a \(p\)-cartesian lift of \(\phi q'\); and

• whose 2-cells are given by quadruples \(\alpha : a \Rightarrow \tilde{a}, \beta : b \Rightarrow \tilde{b}, \) and \(\lambda : \ell \Rightarrow \tilde{\ell}\) in which \(e\) and \(\lambda\) are, respectively, lifts of \(\beta p'\) and \(a q'\) and so that \(\phi \cdot k\alpha = \beta k' \cdot \phi\) and \(\tilde{\chi} \cdot h\lambda = eh' \cdot \chi.\)

These definitions are arranged so that there is an evident forgetful 2-functor \(\mathcal{K}^\circ \rightarrow \mathcal{K}^\circ\) that has the strong surjectivity property introduced in Definition 3.6.1.

5.7.15. Lemma. The forgetful 2-functor \(\mathcal{K}^\circ \rightarrow \mathcal{K}^\circ\) is a smothering 2-functor.

Proof. Proposition 5.2.4 tells us that \(\mathcal{K}^\circ \rightarrow \mathcal{K}^\circ\) is surjective on objects. To see that it is full on 1-cells, first form the pullbacks of the cospans in (5.7.12), then define \(\chi\) to be any \(p\)-cartesian lift of \(\phi q'\) with codomain \(eh'\). By construction, the domain of \(\chi\) lies strictly over \(k a q'\) and so this functor factors uniquely through the pullback leg \(h\) defining the map \(\ell\) of (5.7.14).

To prove that \(\mathcal{K}^\circ \rightarrow \mathcal{K}^\circ\) is full on 2-cells, consider a parallel pair of 1-cells in \(\mathcal{K}^\circ\). For one of these we use the notation of (5.7.14) and for the other we denote the diagonal functors by \(\tilde{a}, \tilde{b}, \tilde{e},\) and \(\tilde{\ell}\) and denote the 2-cells by \(\tilde{\phi}\) and \(\tilde{\chi}\); the requirement that these 1-cells be parallel implies that the pullback faces are necessarily the same. Now consider a triple \(\alpha : a \Rightarrow \tilde{a}, \beta : b \Rightarrow \tilde{b},\) and \(e : e \Rightarrow \tilde{e}\) satisfying the conditions of Definition 5.7.11. Our task is to define a fourth 2-cell \(\lambda : \ell \Rightarrow \tilde{\ell}\) so that \(q\lambda = a q'\) and \(\tilde{\chi} \cdot h\lambda = eh' \cdot \chi.\)
To achieve this, we first define a 2-cell \( \gamma: h \ell \Rightarrow h \ell' \) using the induction property of the \( p \)-cartesian cell \( \tilde{\chi}: h \ell \Rightarrow \tilde{\ell} \) applied to the composite 2-cell \( eh' \cdot \chi: h \ell \Rightarrow \tilde{\ell} \) and the factorization \( peh' \cdot p\chi = \tilde{\phi}q' \cdot \alpha q' \). By construction \( pq = \alpha q' \) so the pair \( \alpha q' \) and \( \gamma \) induces a 2-cell \( \lambda: \ell \Rightarrow \tilde{\ell} \) so that \( q\lambda = \alpha q' \) and \( h\lambda = \gamma \). The quadruple \((\alpha, \beta, \epsilon, \lambda)\) now defines the required 2-cell in \( \mathcal{K}^{\alpha} \).

Finally, for 2-cell conservativity, suppose \( \alpha, \beta, \epsilon \) as above are isomorphisms. By the conservativity property for pullbacks described in Proposition 3.3.1, to show that \( \lambda \) is an isomorphism, it suffices to prove that \( q\lambda = \alpha q' \) is, which we know already, and that \( h\lambda = \gamma \) is invertible. But \( \gamma \) was constructed as a factorization \( eh' \cdot \chi = \tilde{\chi} \cdot \gamma \) with \( pq = \alpha q' \). Since \( e \) is an isomorphism, \( eh' \cdot \chi \) is \( p \)-cartesian, so Lemma 5.1.10 proves that \( \gamma \) is an isomorphism. \( \square \)

We cannot directly define a pullback 2-functor \( \mathcal{K}^{\alpha} \rightarrow \mathcal{K} \) in the homotopy 2-category because the 2-categorical universal property of pullbacks in \( \mathcal{K} \) is weak and not strict. Instead, the zig zag of 2-functors

\[
\mathcal{K}^{\alpha} \leftarrow \mathcal{K} \rightarrow \mathcal{K}
\]

in which the backwards map is a smothering 2-functor and the forwards map evaluates at the pullback vertex, defines a reasonable replacement.

5.7.16. PROPOSITION. Let \( a: 1 \rightarrow A \) define a terminal element of \( A \) and let \( q: F \rightarrow A \) be a cartesian fibration. Then evaluation at \( a \) admits a right adjoint

\[
\begin{array}{c}
\text{Fun}_A(A, F) \downarrow^\sim \text{Fun}(1, F_a) \\
\text{ev}_a \downarrow \ y \\
\text{Fun}(1, A) \downarrow^\sim \text{Fun}(1, F)
\end{array}
\]

that defines an adjoint equivalence of Kan complexes in the case where \( q \) is a discrete cartesian fibration.

PROOF. The desired adjunction is obtained by transferring the adjunction of Lemma 5.7.10 through the sequence of 2-functors

\[
\begin{array}{c}
\mathcal{K}^{\alpha} \rightarrow \mathcal{Q}\text{Cat} \\
\text{ev}_a \downarrow \ y \\
\mathcal{K} \rightarrow \mathcal{Q}\text{Cat}^a
\end{array}
\]

using Lemma 3.6.7 to lift along the middle smothering 2-functor.

Fixing any cartesian fibration \( q: F \rightarrow A \) in \( \mathcal{K} \), we define a 2-functor \( \mathcal{K}_{//A} \rightarrow \mathcal{Q}\text{Cat}^a \) that carries a 1-cell (5.7.8) to

\[
\begin{array}{c}
\mathcal{Q}\text{Cat} \downarrow^\sim \mathcal{Q}\text{Cat}^a \\
\text{ev}_a \downarrow \ y \\
\mathcal{K}_{//A} \rightarrow \mathcal{Q}\text{Cat}^a
\end{array}
\]

and a 2-cell \( \theta: k \Rightarrow k' \) to the 2-cell that acts via pre-whiskering with \( \theta \) in its two non-identity components. By Corollary 5.2.15, the functors \( q_* \) are cartesian fibration of quasi-categories.

\(^{14}\)To explain the variance, recall that the 2-functor \( \text{Fun}(-, A): \mathcal{K}^{\alpha} \rightarrow \mathcal{Q}\text{Cat} \) is contravariant on 1-cells but covariant on 2-cells. Such 2-functors, like all 2-functors, preserve adjunctions, though in this case the left and right adjoints are interchanged, while the units and counits retain the same roles.

192
We now apply the 2-functor $-\vee q_*: \mathcal{K}^\mathbf{op}_A \to \mathbf{qCat}^\mathbf{op}$ to the adjunction of Lemma ?? to obtain an adjunction in $\mathbf{qCat}^\mathbf{op}$ and then use the smothering 2-functor of Lemma 5.7.15 and Lemma 3.6.7 to lift this to an adjunction in $\mathbf{qCat}^\mathbf{op}$. As elaborated on in Exercise 3.6.iii, the lifted adjunction in $\mathbf{qCat}^\mathbf{op}$ can be constructed using any lifts of the objects, 1-cells, and either the unit or counit of the adjunction in $\mathbf{qCat}^\mathbf{op}$.

In particular, we may take the left and right adjoints of the lifted adjunction in $\mathbf{qCat}^\mathbf{op}$ to be any lifts of the images in $\mathbf{qCat}^\mathbf{op}$ of the right and left adjoints of the adjunction $!\dashv a$ in $\mathcal{K}^\mathbf{op}_A$:

\[
\begin{array}{c}
\text{Fun}_A(A,F) \xrightarrow{a} \text{Fun}(A,F) \\
\downarrow \text{id}_A \quad \downarrow \text{id}_A \\
\text{Fun}(1,F_a) \xrightarrow{a} \text{Fun}(1,F) \\
\downarrow \text{id}_A \quad \downarrow \text{id}_A \\
\text{Fun}(\text{Hom}_A(A,a),A) \xrightarrow{a} \text{Fun}(1,A)
\end{array}
\]

and

\[
\begin{array}{c}
\text{Fun}(1,F_a) \xrightarrow{a} \text{Fun}(1,F) \\
\downarrow \text{id}_A \quad \downarrow \text{id}_A \\
\text{Fun}_A(A,F) \xrightarrow{a} \text{Fun}(A,F) \\
\downarrow \text{id}_A \quad \downarrow \text{id}_A \\
\text{Fun}(1,A) \xrightarrow{a} \text{Fun}(A,A)
\end{array}
\]

which shows that the left adjoint is the desired functor. Since the counit of $!\dashv a$ is an identity, the counit of the lifted adjunction may also be taken to be an identity. Finally, we compose with the forgetful 2-functor $\mathbf{qCat}^\mathbf{op} \to \mathbf{qCat}$ that evaluates at the pullback vertex to project our adjunction in $\mathbf{qCat}^\mathbf{op}$ to the desired adjunction in $\mathbf{qCat}$.

When $q: F \to A$ is a discrete isofibration, both $\text{Fun}(1,F_a)$ and $\text{Fun}_A(A,F)$ are Kan complexes. Any adjunction between Kan complexes is automatically an adjoint equivalence, since it follows from Corollary 1.1.21 that any natural transformation whose codomain is a Kan complex is a natural isomorphism.

\[\square\]

5.7.18. EXAMPLE (dependent Yoneda lemma). Recall from Corollary 3.5.10 that for any element $b: 1 \to B$, its identity arrow $\text{id}_b^\uparrow: 1 \to \text{Hom}_B(B,b)$ defines a terminal element. So Theorem 5.7.4 follows immediately as a special case of Proposition 5.7.16.

Using Theorem 5.7.4, we now prove the discrete Yoneda lemma.

**Proof of Theorem 5.7.3.** Let $p: E \to B$ be a discrete cartesian fibration and consider an element $b: 1 \to B$. By Lemma 5.6.7, the pullback

\[
\begin{array}{c}
F \xrightarrow{q} E \\
\downarrow \quad \downarrow p \\
\text{Hom}_B(B,b) \xrightarrow{p_0} B
\end{array}
\]

is relevant.
defines a discrete cartesian fibration over $q$. By pullback composition, the fibers $F_{id_b^*} \cong E_b$ are isomorphic and similarly the space of sections of $q$ is isomorphic to the functor space $\text{Fun}_B(p_0, p)$. So in this context, the equivalence of Theorem 5.7.4 specializes to the desired equivalence of Kan complexes:

$$\text{Fun}_{\text{Hom}}(\text{Hom}(B, b), F) \xrightarrow{ev_{id_b^*}} \text{Fun}(1, F_{id_b^*}) \cong E_b$$

Specializing to the case of two right representable discrete cartesian fibrations, we conclude that the Kan complex of natural transformations is equivalent to the underlying quasi-category of their internal mapping space.

5.7.20. COROLLARY. For any elements $x, y: 1 \to A$ in an $\infty$-category $A$, evaluation at the identity of $x$ induces an equivalence of Kan complexes:

$$\text{Fun}_A(\text{Hom}_A(A, x), \text{Hom}_A(A, y)) \xrightarrow{ev_{id_x^*}} \text{Fun}(1, \text{Hom}_A(x, y)) \cong$$

It remains to prove the general case of Theorem 5.7.6. When $p: E \to B$ is a cartesian fibration the pullback (5.7.19) defines a cartesian fibration $q: F \to \text{Hom}_B(B, b)$ and Proposition 5.7.16 provides an adjunction

$$\text{Fun}_{\text{Hom}}(\text{Hom}(B, b), F) \xrightarrow{ev_{id_b^*}} \text{Fun}(1, F_{id_b^*}) \cong$$

The next step is to observe that the right adjoint lands in the sub quasi-category of cartesian functors from $p_0$ to $p$.

5.7.22. LEMMA. For any cartesian fibration $p: E \to B$ and element $b: 1 \to B$ in an $\infty$-cosmos $\mathcal{K}$, and for each vertex in $\text{Fun}(1, E_b) \cong \text{Fun}_B(b, p)$ below-left:

$$\begin{array}{ccc}
1 & \xrightarrow{e} & E \\
\downarrow_{b} & & \downarrow_{p} \\
B & \xrightarrow{p_0} & B \\
\end{array}$$

the map $ye$ in $\text{Fun}_B(p_0, p)$ above-right defines a cartesian functor in $\mathcal{K}/B$.

PROOF. In the proof of Proposition 5.7.16, the right adjoint is defined by the diagram (5.7.17) as a factorization of the domain component of the $q_*$-cartesian lift of the unit $\eta$ of the adjunction witnessing the terminal element in the base $\infty$-category. Here $q$ is a pullback of the cartesian fibration $p$, and so by Proposition 5.2.4, $y$ can equally be described as a factorization of the domain component of the $p_*$-cartesian lift of $p_0 \eta$, which equals the right comma cone $\phi: p_0 \Rightarrow b!$ in the case of the adjunction.
Thus, by Lemma 5.5.5, we see that \( y_e \) is the domain component of a \( p \)-cartesian lift \( \chi \) of the composite natural transformation below-left:

\[
\begin{align*}
\Hom_B(B, b) & \xrightarrow{\cong} 1 \\
\overset{p_0}{\downarrow} & \quad \overset{\phi}{\downarrow} \\
B & \xrightarrow{\psi} E
\end{align*}
\]

Since \( p_0 : \Hom_B(B, b) \to B \) is discrete, every natural transformation \( \psi \) with codomain \( \Hom_B(B, b) \) is \( p_0 \)-cartesian, so to prove that \( y_e \) defines a cartesian functor, we must show that \( y_e \psi \) is \( p \)-cartesian. To that end, consider the horizontal composite

\[
\begin{align*}
X & \xrightarrow{g} \Hom_B(B, b) \\
\overset{f}{\downarrow} & \quad \overset{\psi}{\downarrow} \\
\Hom_B(B, b) & \xrightarrow{\chi} E
\end{align*}
\]

By naturality of whiskering, we have \( \chi g \cdot y_e \psi = e! \psi \cdot \chi f = \chi f \), since 1 is the terminal \( \infty \)-category and hence \( e! \psi \) is an identity. Now Lemma 5.1.7(ii) implies that \( y_e \psi \) is \( p \)-cartesian. \( \square \)

Now to complete the proof of Theorem 5.7.6, it remains to argue that this restricted adjunction defines an adjoint equivalence.

**Proof of Theorem 5.7.6.** By Lemma 5.7.22, the adjunction (5.7.21) restricts to define an adjunction

\[
\begin{align*}
\Fun_B(p_0, p) \perp \Fun(1, E_b)
\end{align*}
\]

Since the counit of the original adjunction \( ! \dashv \ast \id_b \) is an isomorphism and smothering 2-functors are conservative on 2-cells, the counit of the adjunction of Proposition 5.7.16 and hence also of the restricted adjunction is an isomorphism. As in the proof of Theorem 5.7.3, we will prove that \( \Ev_{\id_B} \) is an equivalence by demonstrating that the unit of the restricted adjunction is also invertible. By Corollary 1.1.21, it suffices to verify this elementwise, proving that the component of the unit indexed
by a cartesian functor

\[
\begin{array}{ccc}
\text{Hom}_B(B, b) & \xrightarrow{h} & E \\
\downarrow{p_0} & & \downarrow{p} \\
B & & B
\end{array}
\]

is an isomorphism.

Unpacking the proof of Proposition 5.7.16, the unit \( \hat{\eta} \) of \( \text{ev}_{\text{id}_b} \) \( \dashv \eta \) is defined to be a factorization

\[
\begin{array}{ccc}
\text{Fun}_B(p_0, p) & \xleftarrow{\eta} & \text{Fun}((\text{Hom}_B(B, b), E) \\
\downarrow{\eta} & & \downarrow{\eta} \\
\text{Fun}((\text{Hom}_B(B, b), E) & \xrightarrow{\eta} & \text{Fun}(1, E)
\end{array}
\]

\[
\begin{array}{ccc}
\text{Fun}_B(p_0, p) & \xrightarrow{\eta} & \text{Fun}((\text{Hom}_B(B, b), E) \\
\downarrow{\eta} & & \downarrow{\eta} \\
\text{Fun}((\text{Hom}_B(B, b), E) & \xrightarrow{\eta} & \text{Fun}(1, E)
\end{array}
\]

of the restriction of \( \text{Fun}(\eta, E) \) through the \( p_0 \)-cartesian lift \( \chi \), where \( \eta \) is the unit of the adjunction \( ! \dashv \eta \). The component of the restricted 2-cell \( \text{Fun}(\eta, E) \) at the cartesian functor \( h \) is \( h \eta \). Since \( p_0: \text{Hom}_B(B, b) \to B \) is a discrete cartesian fibration, any 2-cell, such as \( \eta \), which has codomain \( \text{Hom}_B(B, b) \) is \( p_0 \)-cartesian, and since \( h \) is a cartesian functor, we then see that \( h \eta \) is \( p \)-cartesian.

By Lemma 5.5.8, the components of the \( p_0 \)-cartesian cell \( \chi \) define \( p \)-cartesian natural transformations in the ambient \( \infty \)-cosmos. As \( \hat{\eta} \) is a natural transformation with codomain \( \text{Fun}_B(p_0, p) \) its components project along \( p \) to the identity. In this way, we see that \( \hat{\eta} h \) is a factorization of the \( p \)-cartesian transformation \( h \eta \) through a \( p \)-cartesian lift of \( \phi \) over an identity, and Lemma 5.1.10 proves that \( \hat{\eta} h \) is an isomorphism, as desired.

In \( \infty \)-cosmology we have access to the following trick: any result, such as Theorem 5.7.6, that is proven in a generic \( \infty \)-cosmos can then be applied to a sliced \( \infty \)-cosmos. This can often be used to extend a result about elements of an \( \infty \)-category to generalized elements of that \( \infty \)-category; see Remark 4.3.12 for instance. By this technique, Theorem 5.7.6 implies the following generalization, replacing the elements \( b: 1 \to B \) by a generalized element \( b: X \to B \).

5.7.23. COROLLARY. For any cartesian fibration \( p: E \to B \) and functor \( b: X \to B \), restricting along the canonical induced functor

\[
\begin{array}{ccc}
X & \xrightarrow{\text{id}_b} & \text{Hom}_B(B, b) \\
\downarrow{b} & & \downarrow{p_0} \\
B & & B
\end{array}
\]

defines an equivalence of quasi-categories:

\[
\text{Fun}_B^\text{cart}(\text{Hom}_B(B, b) \to B, E \xrightarrow{p} B) \xrightarrow{\text{ev}_{\text{id}_b}} \text{Fun}_B(X \xrightarrow{b} B, E \xrightarrow{p} B).
\]
**Proof.** Theorem 5.7.6 applies in $\mathcal{K}/X$ to the cartesian fibration $p \times X : E \times X \to B \times X$ and the element $(b, X) : X \to B \times X$ to define an equivalence

$$
\text{Fun}^\text{cart}_{B \times X}(\text{Hom}_B(B, p) \xrightarrow{(p_1, p_0)} B \times X, p \times X) \xrightarrow{\text{ev}_{\text{id}_{(b, X)}}} \text{Fun}^\text{cart}_{B \times X}(X \xrightarrow{(b, X)} B \times X, p \times X)
$$

$$
\text{Fun}^\text{cart}_B(\text{Hom}_B(B, b) \xrightarrow{p_0} B, E \xrightarrow{p} B) \xrightarrow{\text{ev}_{\text{id}_{b}}} \text{Fun}_B(X \xrightarrow{b} B, E \xrightarrow{p} B)
$$

which transposes under the adjunction

$$
\mathcal{K}/X \xRightarrow{\dashv} \mathcal{K}
$$

to the equivalence of the statement. □

Corollary 5.7.23 can be interpreted as defining a “left biadjoint” to the inclusion $\text{Cart}(\mathcal{K})_B \hookrightarrow \mathcal{K}_B$ of the subcategory of cartesian fibrations and cartesian functors, defined on objects by the functor $(b : X \to B) \mapsto (p_0 : \text{Hom}_B(B, b) \to B)$.

**Exercises.**

5.7.i. **Exercise.** Given an element $f : 1 \to \text{Hom}_A(x, y)$ in the internal mapping space between a pair of elements in an $\infty$-category $A$, use the explicit description of the inverse equivalence to the map of Corollary 5.7.20 to construct a map

$$
\text{Hom}_A(A, x) \xrightarrow{\sim} \text{Hom}_A(A, y)
$$

which represents the “natural transformation” defined by post-composing with $f$.\footnote{Hint: this construction is a special case of the construction given in the first half of the proof of Lemma 5.7.22.}

197
An Interlude on $\infty$-Cosmology
CHAPTER 6

Exotic $\infty$-Cosmoi

Morally an $\infty$-cosmos can be described as “an $(\infty, 2)$-category with $(\infty, 2)$-categorical limits,” but the precise axiomatization given in Definition 1.2.1 employs a particularly strict interpretation of this phrase, taking advantage of the strictness that is available in so many examples to simplify proofs. We define $\infty$-cosmoi to be quasi-categorically enriched categories, selecting the strictest model of $(\infty, 2)$-categories in common use [75, 0.0.3-4], and we construct $(\infty, 2)$-categorical limits by certain homotopically well-behaved simplicially enriched limits, as will be elaborated on momentarily.

Our aim in this chapter is to develop further examples of $\infty$-cosmoi, which will immediately allow us to apply all of the theorems proven in Part I in more exotic contexts, where the $\infty$-categories of an $\infty$-cosmos should not be thought of as “$(\infty, 1)$-categories in some model.” Some of these examples, such as the $\infty$-cosmos of isofibrations introduced in §6.1, can be established easily by directly verifying the axioms of Definition 1.2.1.

A larger family of examples, appearing in §6.4, arise as subcategories of previously-defined $\infty$-cosmoi. For instance, in Proposition 6.4.13 we prove that the $\infty$-cosmos of isofibrations $\mathcal{K}$ in any $\infty$-cosmos $\mathcal{K}$ has a sub $\infty$-cosmos $\mathcal{C}art(\mathcal{K})$ of cartesian fibrations and cartesian functors between them. This result, and many others of a similar flavor, follow from a common paradigm appearing as Proposition 6.4.3, which states that a replete subcategory (see Definition 6.4.1) of an $\infty$-cosmos inherits an $\infty$-cosmos structure provided that it is closed under flexible weighted limits.

This leads us to the second main theme of this chapter: an elaboration of the $(\infty, 2)$-categorical limits present in any $\infty$-cosmos. In §6.3, we discover that the cosmological limit notions enumerated in axiom 1.2.1(i) generate a much larger class of simplicially enriched limits which then exist in any $\infty$-cosmos, which are precisely those simplicially enriched limits that deserve to be called “$(\infty, 2)$-categorical limits.” This class of limits is introduced in §6.2 under the name flexible weighted limits, borrowing a term from 2-category theory — see Digression 6.2.7.

To explain the intuition, we recall the formalism of weighted limits from §A.6. An ordinary limit defines a universal cone over a given diagram, each cone leg being an arrow whose source is the limit object. A weighted limit similarly defines a universal cones over over a given diagram, but now that cone might take a more exotic shape. In the simplicially enriched context, each cone leg may take the shape of an arbitrary simplicial set, with the cone-commutativity conditions then specified by a simplicial-set-valued simplicial functor, referred to as the weight. For example, an ordinary cone over a cospan defines a commutative square, but the cones for a different choice of weight are squares inhabited by a 1-simplex. In this way, the comma $\infty$-categories of Definition 3.4.1 arise as weighted limits of cospans; see Example A.6.14.

Intuitively, the flexible weighted limits are those whose weights define cone shapes that do not impose any strict commutativity conditions: pullbacks are not flexible weighted limits, while comma objects are. Flexible weighted limits are also equivalence invariant, while general weighted limits need not be. These are the senses in which flexible weighted limits correspond to $(\infty, 2)$-categorical limit notions.

201
We prove these results in §6.3 and also see that the cosmological limits enumerated in axiom 1.2.1(i), such as pullbacks of isofibrations, are really flexible weighted limits in disguise. The requirement that certain arrows in the diagram are isofibrations means that strictly commuting cones correspond to pseudo-commutative cones, providing the required flexibility.

This chapter closes with a few sample applications of the general \( \infty \)-cosmology developed here. More will follow in Part II, where we use the \( \infty \)-cosmoi constructed here to develop the theory of two-sided fibrations and modules.

### 6.1. The \( \infty \)-Cosmos of Isofibrations

Our first example of an “exotic \( \infty \)-cosmos” is a special case of a more general result that is left as Exercise 6.1.iii. The walking arrow category \( \mathbb{2} \) is an inverse Reedy category, where the domain of the non-identity arrow is assigned “degree one” and the codomain is assigned “degree zero.” This Reedy structure motivates the definitions in the \( \infty \)-cosmos of isofibrations that we now introduce:

**6.1.1. Proposition (\( \infty \)-cosmoi of isofibrations).** For any \( \infty \)-cosmos \( \mathcal{K} \) there is an \( \infty \)-cosmos \( \mathcal{K}^\bullet \) whose

(i) objects are isofibrations \( p : E \to B \) in \( \mathcal{K} \),

(ii) functor spaces, say from \( q : F \to A \) to \( p : E \to B \), are defined by pullback

\[
\begin{array}{ccc}
\text{Fun}(F \to A, E \to B) & \longrightarrow & \text{Fun}(F, E) \\
\downarrow & & \downarrow p_* \\
\text{Fun}(A, B) & \longrightarrow & \text{Fun}(F, B),
\end{array}
\]

(iii) isofibrations from \( q \) to \( p \) are commutative squares

\[
\begin{array}{ccc}
F & \longrightarrow & E \\
\downarrow q & & \downarrow p \\
A & \longrightarrow & B
\end{array}
\]

in which the horizontals and the induced map from the initial vertex to the pullback of the cospan are isofibrations in \( \mathcal{K} \),

(iv) limits are defined pointwise in \( \mathcal{K} \),

(v) and in which a map

\[
\begin{array}{ccc}
F & \longrightarrow & E \\
\downarrow q & & \downarrow p \\
A & \longrightarrow & B
\end{array}
\]

is an equivalence in the \( \infty \)-cosmos \( \mathcal{K}^\bullet \) if and only if \( g \) and \( f \) are equivalences in \( \mathcal{K} \).

Relative to these definitions, the domain, codomain, and identity functors

\[
\begin{array}{ccc}
\mathcal{K}^\bullet & \leftarrow & \text{id} \rightarrow & \mathcal{K} \\
\downarrow \text{dom} & & & \downarrow \text{cod}
\end{array}
\]

are all cosmological.
Proof. The diagram category $\mathcal{K}^\bullet$ inherits its simplicially enriched limits, defined pointwise, from $\mathcal{K}$. The functor spaces described in (ii) are the usual ones for an enriched category of diagrams. This verifies 1.2.1(i). Note that the definitions of limits and isofibrations make each of the domain, codomain, and identity functors cosmological.

For axiom 1.2.1(ii) note that the product and simplicial cotensor functors carry pointwise isofibrations to isofibrations. The pullback of an isofibration as in (iii) along a commutative square from an isofibration to $p$ may be formed in $\mathcal{K}$. Our task is to show that the induced map $t$ is an isofibration and also that the square from $t$ to $r$ is an isofibration in the sense of (iii):

\[ \begin{array}{cccc}
G \times F & \rightarrow & F \\
\downarrow & & \downarrow \\
C \times A & \rightarrow & A \\
\end{array} \]

(6.1.2)

The map $t$ factors as a pullback of $z$ followed by a pullback of $r$ as displayed above, and is thus an isofibration, as claimed. This observation also verifies that the square from $t$ to $r$ defines an isofibration. A similar argument verifies the Leibniz stability of the isofibrations and that the limit of a tower of isofibrations is an isofibration. This proves that $\mathcal{K}^\bullet$ defines an $\infty$-cosmos in such a way so that the domain, codomain, and identity functors are cosmological.

Finally, by Proposition 3.3.3, a pair of equivalences $(g, f)$ induces an equivalence between the functor spaces defined in (ii). The converse, that an equivalence in $\mathcal{K}^\bullet$ defines a pair of equivalences in $\mathcal{K}$ follows from the fact that domain and codomain-projection functors are cosmological and Lemma 1.3.2. □

In close analogy with Proposition 3.6.2 we have a smothering 2-functor that relates the homotopy 2-category of $\mathcal{K}^\bullet$ to the 2-category of isofibrations, commutative squares, and parallel natural transformations in the homotopy 2-category of $\mathcal{K}$.

6.1.3. Lemma. There is an identity on objects and 1-cells smothering 2-functor $\mathcal{K}^\bullet \rightarrow (\mathcal{K})^\bullet$ whose codomain is the 2-category whose

- objects are isofibrations in $\mathcal{K}$,
- 1-cells are commutative squares between such,
- 2-cells are pairs of 2-cells in $\mathcal{K}$

\[ \begin{array}{cccc}
F & \rightarrow & E \\
\downarrow & & \downarrow \\
A & \rightarrow & B \\
\end{array} \]

so that $p\alpha = \beta q$.

Proof. Exercise 6.1.i. □
Similarly, any ∞-cosmos admits an ∞-cosmos of trivial fibrations, which can be defined as a full subcategory of the ∞-cosmos of isofibrations. The following general result from abstract ∞-cosmology explains how it inherits its ∞-cosmos structure.

6.1.4. Lemma. Let $\mathcal{K}$ be an ∞-cosmos and let $\mathcal{L} \subseteq \mathcal{K}$ be a full subcategory. Then $\mathcal{L}$ inherits an ∞-cosmos structure from $\mathcal{K}$ created from the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$ if and only if $\mathcal{L}$ is closed in $\mathcal{K}$ under the cosmological limit notions enumerated in axiom 1.2.1(i).

In practice, the full subcategories we consider have the property that any object of $\mathcal{K}$ that is equivalent to an object in $\mathcal{L}$ in fact lies in $\mathcal{L}$—in other words, these subcategories are “replete” in the sense of Definition 6.4.1. In the proof below, we tacitly assume that $\mathcal{L}$ is at least closed under isomorphism so that if a limit of a diagram lies in $\mathcal{L}$ then all of the limits of that diagram do, but this assumption is only used for linguistic convenience and is inessential.

Proof. As a full subcategory, $\mathcal{L}$ inherits its quasi-categorical enrichment from $\mathcal{K}$, and we define a map to be an isofibration in $\mathcal{L}$ if and only if it is an isofibration in $\mathcal{K}$. Note this definition makes axiom 1.2.1(ii) follow immediately once we've shown that the limits required by 1.2.1(i) coincide with the corresponding limits in $\mathcal{K}$. But this is exactly what is asserted by the hypothesis that $\mathcal{L}$ is closed in $\mathcal{K}$ under the cosmological limit notions.

We've shown that a closed full subcategory inherits an ∞-cosmos structure defined in such a way that the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$ is a cosmological functor that reflects isofibrations and cosmological limits. Clearly, this inclusion reflects representably-defined equivalences, since $\mathcal{L}$ is a full subcategory of $\mathcal{K}$. But by Lemma 1.3.2 the cosmological functor $\mathcal{L} \hookrightarrow \mathcal{K}$ preserves them as well, which tells us that equivalences in $\mathcal{L}$ are created from $\mathcal{K}$ along with the isofibrations and cosmological limits. □

With this result in hand, we leave the details of the proof of the ∞-cosmos of trivial fibrations to the reader.

6.1.5. Proposition (∞-cosmii of trivial fibrations). Let $\mathcal{K}$ be an ∞-cosmos.

(i) For any ∞-category $B$ in $\mathcal{K}$, the full subcategory $\mathcal{K}_B \hookrightarrow \mathcal{K}$ spanned by the trivial fibrations with codomain $B$ defines an ∞-cosmos, with limits, isofibrations, equivalences, and trivial fibrations created by the inclusion.

(ii) The full subcategory $\mathcal{K}^\# \hookrightarrow \mathcal{K}$ spanned by the trivial fibrations defines an ∞-cosmos, with limits, isofibrations, equivalences, and trivial fibrations created by the inclusion.

Proof. The details, which are similar to Propositions 1.2.22 and 6.1.1, are left to Exercise 6.1.ii. □

Note that the sliced ∞-cosmii $\mathcal{K}_B$ of trivial fibrations are weakly contractible in the following sense: the functor spaces are contractible Kan complexes, the unique functor $\mathcal{K}_B^\# \Rightarrow 1$ to the terminal ∞-cosmos is a cosmological biequivalence. In particular, each functor in $\mathcal{K}_B^\#$ is an equivalence, so this ∞-cosmos is more a curiosity than a structure of substantial interest.

As promised in §1.2, Lemma 6.1.4 allows us to generalize Proposition 1.2.12 to show that the discrete ∞-categories in any ∞-cosmos form an ∞-cosmos:

6.1.6. Proposition (∞-cosmii of discrete ∞-categories). The full subcategory $\mathcal{K}^\# \hookrightarrow \mathcal{K}$ spanned by the discrete ∞-categories in any ∞-cosmos form an ∞-cosmos.

Proof. Recall from Lemma 1.2.27 that an ∞-category $A$ in an ∞-cosmos $\mathcal{K}$ is discrete if and only if the map $A^\# \rightarrow A^2$ is a trivial fibration. This says that the full subcategory $\mathcal{K}^\# \hookrightarrow \mathcal{K}$ of discrete
\(\infty\)-categories is defined by the pullback

\[
\begin{array}{ccc}
\mathcal{K}^\infty & \xrightarrow{\sim} & \mathcal{K}^\triangleright \\
\downarrow & & \downarrow \\
\mathcal{K} & \xrightarrow{E} & \mathcal{K}^\star
\end{array}
\]

along the cosmological functor \(E\) that sends an \(\infty\)-category \(A\) to the isofibration \(A^\parallel \rightarrow A^2\). By Lemma 6.1.4, to show that \(\mathcal{K}^\infty\) admits an \(\infty\)-cosmos structure inherited from \(\mathcal{K}\), we need only show that the discrete \(\infty\)-categories are closed in \(\mathcal{K}\) under the limit constructions of 1.2.1(i). For the simplicial cotensors, for instance, this follows easily from the defining universal property and the fact that the Kan complexes form an exponential ideal in the category of simplicial sets. A common argument can be given for each of the conical limits; for sake of concreteness, consider a tower of isofibrations between discrete \(\infty\)-categories \(A_n\) and form the limit in \(\mathcal{K}\)

\[
A := \lim \left( \ldots \longrightarrow A_n \longrightarrow A_{n-1} \longrightarrow \cdots \longrightarrow A_1 \longrightarrow A_0 \right)
\]

The cosmological functor \(E\) carries this to a limit diagram in the \(\infty\)-cosmos \(\mathcal{K}^\star\)

\[
\begin{array}{ccc}
A^\parallel & \xrightarrow{\sim} & A^2 \\
\downarrow & & \downarrow \\
A & \xrightarrow{\lim} & A^2
\end{array}
\]

Since each \(A_n\) is a discrete \(\infty\)-category, each of the objects in this diagram is a trivial fibration. Hence, by Proposition 6.1.5, the limit \(A^\parallel \rightarrow A^2\) is a trivial fibration as well. This proves that \(A\) is discrete. \(\square\)

The proof of Proposition 6.1.1 revealed that it's tedious to manually verify the limit axiom in the construction of new \(\infty\)-cosmoi; indeed, even in that relatively basic example, we omitted some details. In the following sections, we develop machinery that will allow us to attack this problem more systematically.

**Exercises.**

6.1.i. **Exercise.** Prove Lemma 6.1.3.

6.1.iii. **Exercise.** Let \(\mathcal{K}\) be an \(\infty\)-cosmos and let \(I\) be an inverse category, in the sense of Definition C.1.16. Guided by Proposition C.1.23, prove that there is an \(\infty\)-cosmos \(\mathcal{K}^I\) whose:

- objects are the *fibrant diagrams* of Definition C.1.19,
- isofibrations are the *fibrant natural transformations* of Definition C.1.19,
- functor spaces are the simplicial hom-spaces of Definition A.3.8, which are quasi-categories by the proof of Theorem C.5.15,
- and in which the simplicial limits and equivalences are defined pointwise in \(\mathcal{K}\).

Use Proposition C.1.21 to demonstrate that limits of fibrant \(I\)-indexed diagrams exist in \(\mathcal{K}\) and moreover that the functor \(\lim: \mathcal{K}^I \rightarrow \mathcal{K}\) is cosmological.
6.2. Flexible Weighted Limits and the Collage Construction

Our aim in this section is to introduce a special class of simplicial-set-valued weights whose associated weighted limit notions are homotopically well-behaved. Borrowing a term from 2-category theory, we refer to these weights as *flexible*. All of the limits enumerated in axiom 1.2.1(i) are flexible limits. In fact, in §6.3 we prove that ∞-cosmoi admit all flexible weighted limits because these can be built out of the limits enumerated in 1.2.1(i). In §6.4, we make use of this observation to help us more efficiently verify the limit axiom for newly constructed ∞-cosmoi.

In this section, we characterize the class of flexible weights as precisely those whose associated cone shapes, which we refer to as the *collages* of the weights, define *relative simplicial computads*. Roughly, this means that the simplices appearing in a cone are freely attached, relative to the diagram shape. This characterization, which appears as Theorem 6.2.14, will allow us to readily produce examples.

In §6.3, we will establish the homotopical properties of flexible weighted limits and make precise the relationships between this class of limits and the limits assumed present in any ∞-cosmos by axiom 1.2.1(i).

If the notion of weighted limits in enriched category theory is unfamiliar, we suggested reading §A.4-A.6 before proceeding.

6.2.1. Definition (flexible weights and projective cell complexes). Let \( \mathcal{A} \) be a simplicial category and consider the category \( \text{sSet}^\mathcal{A} \) of simplicial functors, called *weights*, and simplicial natural transformations.

- For any \( n \geq 0 \) and object \( a \) of \( \mathcal{A} \) a simplicial natural transformation of the form
  \[
  \partial \Delta[n] \times \mathcal{A}(a, -) \to \Delta[n] \times \mathcal{A}(a, -)
  \]
  is called a *projective* \( n \)-cell at \( a \).

- A simplicial natural transformation \( \alpha: V \hookrightarrow W \) that can be expressed as a countable composite of pushouts of coproducts of projective cells is called a *projective cell complex*.

- A weight \( W \) is *flexible* just when \( \emptyset \hookrightarrow W \) is a projective cell complex.

A **flexible weighted limit** of a diagram \( F: \mathcal{A} \to \mathcal{K} \) valued in an ∞-cosmos is a weighted limit, in the sense of §A.6, whose weight \( W: \mathcal{A} \to \text{sSet} \) is flexible.

6.2.2. Remark (on generalized projective cells). Since any monomorphism of simplicial sets \( U \hookrightarrow V \) can be decomposed as a countable composite of pushouts of coproducts of boundary inclusions \( \partial \Delta[n] \hookrightarrow \Delta[n] \), the class of projective cell complexes may be also be described as the class of maps in \( \text{sSet}^\mathcal{A} \) that can be expressed as a countable composite of pushouts of coproducts of monomorphisms of the form \( U \times \mathcal{A}(a, -) \hookrightarrow V \times \mathcal{A}(a, -) \) for some \( a \in \mathcal{A} \).

6.2.3. Example (cotensors are flexible). Recall from §A.4 that the *cotensor* of an ∞-category \( A \) in an ∞-cosmos \( \mathcal{K} \) with a simplicial set \( U \) is the object \( A^U \in \mathcal{K} \) characterized by the simplicial natural isomorphism

\[
\text{Fun}(X, A^U) \cong \text{Fun}(X, A)^U.
\]

This object can be regarded as the limit of the diagram \( A: 1 \to \mathcal{K} \) weighted by \( U: 1 \to \text{sSet} \). Since any simplicial set can be decomposed as a countable composite of pushouts of coproducts of boundary inclusions \( \partial \Delta[n] \hookrightarrow \Delta[n] \), simplicial cotensors are flexible weights, built from a single generalized projective cell at the unique object of \( 1 \).
Recall from §A.5 that the conical limit of a diagram \( F: \mathcal{A} \rightarrow \mathcal{K} \) is the limit weighted by the terminal weight \(*: \mathcal{A} \rightarrow sSet\).

6.2.4. Example (products are flexible). Conical products also define flexible weighted limits, built by attaching one projective 0-cell for each object in the indexing set.

6.2.5. Non-Example. Conical limits indexed by any 1-category that contains non-identity arrows are not flexible because the legs of a conical cone over the domain and codomain of each arrow in the diagram are required to define a strictly commutative triangle of 0-arrows; see Example 6.2.16 for instance. The specifications for a flexible weight allow us to freely attach \( n \)-arrows of any dimension, but do not provide a mechanism for demanding strict commutativity of any diagram of \( n \)-arrows — only commutativity up to the presence of a higher cell.

6.2.6. Example (commas are flexible). As explained in Example A.6.14, in an \( \infty \)-cosmos \( \mathcal{K} \), the comma \( \infty \)-category \( \text{Hom}_A(f, g) \) is the limit of the diagram \( \triangleright \rightarrow \mathcal{K} \) given by the cospan

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A \\
& \searrow & \downarrow f \\
& & B
\end{array}
\]

weighted by the diagram \( \triangleright \rightarrow sSet \) given by the cospan

\[
\begin{array}{ccc}
1 & \xrightarrow{1} & 2 \\
& \searrow & \downarrow 0 \\
& & 1
\end{array}
\]

Since this weight can be built by attaching two projective 0-cells at the corners of the cospan followed by a projective 1-cell at the terminal object of the cospan, comma objects are flexible weighted limits.

6.2.7. Digression (on flexible limits in 2-category theory). Simplicial limits weighted by flexible weights should be thought of as analogous to flexible 2-limits, i.e., 2-limits built out of products, inserters, equifiers, and retracts (splittings of idempotents) \([17]\). Because we define flexible weights as countable composites of pushouts of coproducts—and not retracts thereof—more precisely, simplicial limits weighted by flexible weights are analogous to the PIE limits, those built just from products, inserters, and equifiers. The PIE limits also include iso-inserters, descent objects, comma objects, and Eilenberg-Moore objects, as well as all pseudo, lax, and oplax limits. Many important 2-categories, such as the 2-category of accessible categories and accessible functors, fail to admit all 2-categorical limits, but do admit all PIE-limits \([81]\).

The weights for flexible limits are the cofibrant objects in a model structure on the diagram 2-category \( \mathcal{C}at^\mathcal{A} \) that is enriched over the folk model structure on \( \mathcal{C}at \); the PIE weights are exactly the cellular cofibrant objects. Correspondingly, the projective cell complexes of Definition 6.2.1 are exactly the cellular cofibrations in the projective model structure on \( sSet^\mathcal{A} \).

This suggests that “PIE limits” would be a more precise name for the flexible weighted limits of Definition 6.2.1 and we do not disagree. With apologies to the Australian 2-category theory diaspora, we cannot resist adopting the more evocative term.

Recall that a weight is intended to describe the “shape” of cones over diagrams indexed by a particular category. In the case a weight \( W: \mathcal{A} \rightarrow sSet \) valued in simplicial sets, we can describe the shape of \( W \)-cones directly by building a simplicial category, called the collage of the weight, that adds an additional object to \( \mathcal{A} \) to serve as the apex of the \( W \)-shaped cone.

6.2.8. Definition (collage construction). The collage of a weight \( W: \mathcal{A} \rightarrow sSet \) is a simplicial category \( \text{coll}W \) which contains \( \mathcal{A} \) as a full subcategory together with one additional object \( \top \) whose
endomorphism space is the point. The mapping spaces from any object $a \in \mathcal{A}$ to $\top$ are empty, while the mapping spaces from $\top$ to the image of $\mathcal{A} \hookrightarrow \text{coll}W$ are defined by:

$$\text{coll}W(\top, a) \coloneqq W(a)$$

with the action maps $\mathcal{A}(a, b) \times W(a) \to W(b)$ from the simplicial functor $W$ used to define composition. This defines a simplicial category together with a canonical inclusion $\mathbf{1} + \mathcal{A} \hookrightarrow \text{coll}W$ that is bijective on objects and fully faithful on $\mathbf{1}$ and $\mathcal{A}$ separately.

To define a simplicial functor $W : \mathcal{A} \to s\text{Set}$ requires no more and no less than

- the specification of simplicial sets $W(a)$ for each $a \in \mathcal{A}$ and
- and the specification of simplicial maps $\mathcal{A}(a, b) \times W(a) \to W(b)$ for each $a, b \in \mathcal{A}$

so that this action is associative in sense that the diagram

$$\begin{array}{ccc}
\mathcal{A}(b, c) \times \mathcal{A}(a, b) \times W(a) & \to & \mathcal{A}(a, c) \times W(a) \\
\downarrow & & \downarrow \\
\mathcal{A}(b, c) \times W(b) & \to & W(c)
\end{array}$$

commutes. This is the same as what is required to extend $\mathbf{1} + \mathcal{A}$ to a simplicial category with those same objects in which all of the additional maps start at $\top$ and end at an object in $\mathcal{A}$. This suggests that we might productively identify weights with the full subcategory of the slice category $\mathbf{1} + \mathcal{A}_{s\text{Set-Cat}}$ spanned by their collages:

6.2.9. PROPOSITION (collage adjunction).

(i) The collage construction defines a fully faithful functor

$$s\text{Set}^\mathcal{A} \xrightarrow{\text{coll}} 1 + \mathcal{A}_{s\text{Set-Cat}}$$

from the category of $\mathcal{A}$-indexed weights to the category of simplicial categories under $\mathbf{1} + \mathcal{A}$ whose essential image is comprised of those $\langle e, F \rangle : \mathbf{1} + \mathcal{A} \to \mathcal{E}$ that are bijective on objects, fully faithful when restricted to $\mathbf{1}$ and $\mathcal{A}$, and have the property that there are no arrows in $\mathcal{E}$ from the image of $F$ to $e$.

(ii) The collage functor admits a right adjoint

$$s\text{Set}^\mathcal{A} \xleftarrow{\text{weight}} 1 + \mathcal{A}_{s\text{Set-Cat}}$$

which carries a pair $\langle e, F \rangle : \mathbf{1} + \mathcal{A} \to \mathcal{E}$ to the weight $\mathcal{E}(e, F-): \mathcal{A} \to s\text{Set}$.

PROOF. The construction of the collage functor and characterization of its essential image is straightforward and left to the reader.

The adjunction asserts that simplicial functors

$$\text{coll}W \xrightarrow{(e,F)} \mathcal{E}$$

208
from \( \text{coll} W \) to \( \mathcal{E} \) under \( 1 + \mathcal{A} \) stand in natural bijective correspondence with simplicial natural transformations \( \gamma: W \Rightarrow \mathcal{E}(e, F-) \). Since the inclusion \( 1 + \mathcal{A} \hookrightarrow \text{coll} W \) is bijective on objects and full on most homs, the data of the simplicial functor requires only the specification of the maps \( \text{coll} W(\tau, a) = W(a) \rightarrow \mathcal{E}(e, F\tau) \). These define the components of the simplicial natural transformation \( \gamma \) and functoriality of \( G \) corresponds to naturality of \( \gamma \).

The collage adjunction has a useful and important interpretation.

6.2.10. **Corollary.** The collage of a weight \( W: \mathcal{A} \rightarrow \text{sSet} \) realizes the shape of \( W \)-weighted cones in the sense that simplicial functors \( G: \text{coll} W \rightarrow \mathcal{E} \) with domain \( \text{coll} W \) stand in bijection to \( W \)-cones over the diagram \( G|\mathcal{A} \) with summit \( G(\top) \).

A particularly convenient aspect of the collage construction is that it allows us to detect the class of flexible weights vis-à-vis a notion that we now introduce.

6.2.11. **Definition (relative simplicial computad).** The class of all relative simplicial computads is the class of all simplicial functors that can be expressed as a countable composite of pushouts of coproducts of

- the unique simplicial functor \( \emptyset \hookrightarrow 1 \) and
- the simplicial subcomputad inclusion \( 2[\partial \Delta[n]] \hookrightarrow 2[\Delta[n]] \) for \( n \geq 0 \),

where for any simplicial set \( U \), \( 2[U] \) denotes the simplicial category with two objects “−” and “+” and with hom-spaces defined by

\[
2[U](+, -) := \emptyset, \quad 2[U](+, +) := 1 =: 2[U](-, -,), \quad 2[U](-, +) := U.
\]

6.2.12. **Digression.** A simplicial category \( \mathcal{A} \) is a simplicial computad just when \( \emptyset \hookrightarrow \mathcal{A} \) is a relative simplicial computad. This characterization agrees with the following elementary characterization of “free” simplicial categories, first introduced by Dwyer and Kan [38, 4.5]:

- Each category \( \mathcal{A}_n \) of \( n \)-arrows is freely generated by the graph of atomic \( n \)-arrows.
- If \( f \) is an atomic \( n \)-arrow in \( \mathcal{A}_n \) and \( \sigma: [m] \rightarrow [n] \) is an epimorphism in \( \Delta \), then the degenerated \( m \)-arrow \( f \cdot \sigma \) is atomic in \( \mathcal{A}_m \).

Note that the domains of relative simplicial computads need not be simplicial computads, but when they are the relative simplicial computads coincide with the simplicial subcomputad inclusions: maps of simplicial computads that are injective on objects and preserve atomic arrows. See [107, §4.1] for more discussion.

6.2.13. **Digression.** The category of simplicial categories bears a model structure due to Bergner whose fibrant objects are the Kan complex enriched categories. The weak equivalences, called DK-equivalences after Dwyer and Kan, are simplicial functors \( F: \mathcal{C} \rightarrow \mathcal{D} \) whose action on homs

\[
F_{x,y}: C(x, y) \Rightarrow D(Fx, Fy)
\]

An arrow \( f \) in a 1-category is atomic if it is not an identity and if it admits no non-trivial factorizations: i.e., if whenever \( f = g \circ h \), either \( g \) or \( h \) is an identity. A 1-category is free if every arrow may be expressed uniquely as a composite of atomic arrows, with the convention that empty composites correspond to identity arrows. Alternatively, a 1-category is free if every non-identity arrow may be expressed uniquely as a non-empty composite of atomic arrows and if identity arrows admit no non-trivial factorizations.
is via weak homotopy equivalences of simplicial sets and which induce equivalences of homotopy categories.² The fibrations are defined by a similar pair of conditions: these are simplicial functors $F: C \to D$ whose action on homs

$$F_{x,y}: C(x,y) \to D(Fx,Fy)$$

is via a Kan fibration of simplicial sets and which have the property that a 0-arrow $f:Fc \to d$ that defines an isomorphism in the homotopy category of $D$ may be lifted to a 0-arrow $g: c \to c'$ that defines an isomorphism in the homotopy category of $C$. More details can be found in the original [12] or in the survey text [14].

The morphisms listed in Definition 6.2.11 are the generating cofibrations in the Bergner model structure. Hence, the relative simplicial computads are precisely the cellular cofibrations, those that are built as sequential composites of pushouts of coproducts of generating cofibrations (without closing under retracts). It follows from the characterization of simplicial computads given in Digression 6.2.12 that every retract of a simplicial computad is a simplicial computad. Hence, the cofibrant objects in the Bergner model structure are exactly the simplicial computads. However, for non-cofibrant domains, the notion of Bergner cofibration is more general than the notion of relative simplicial computad.

6.2.14. **Theorem** (flexible weights and collages). A natural transformation $\alpha: V \hookrightarrow W$ between weights in $sSet^{\mathcal{A}}$ is a projective cell complex if and only if $\text{coll}(\alpha): \text{coll}V \hookrightarrow \text{coll}W$ is a relative simplicial computad. In particular, $W$ is a flexible weight if and only if $\mathbb{1} + \mathcal{A} \hookrightarrow \text{coll}W$ is a relative simplicial computad.

**Proof.** If $\alpha: V \hookrightarrow W$ is a projective cell complex, then it can be presented as a countable composite of pushouts of coproducts of projective cells of varying dimensions indexed by the objects $a \in \mathcal{A}$. Since the collage construction is a left adjoint, it preserves these colimits, and hence the map $\text{coll}(\alpha): \text{coll}V \hookrightarrow \text{coll}W$ is a countable composite of pushouts of coproducts of simplicial functors $\text{coll}(\partial \Delta[n] \times \mathcal{A}(a,-)) \hookrightarrow \text{coll}(\Delta[n] \times \mathcal{A}(a,-))$ in $\mathbb{1} + \mathcal{A}/sSet\text{-Cat}$. While the sequential colimit and pushouts in this cell complex presentation are preserved by the forgetful functor $\mathbb{1} + \mathcal{A}/sSet\text{-Cat} \to sSet\text{-Cat}$, the coproducts of collages of projective cells are sent to pushouts over $\mathbb{1} + \mathcal{A}$ in $sSet\text{-Cat}$. However, a pushout over a simplicial category $\mathcal{B}$ of two maps under $\mathcal{B}$ is itself a pushout of the coproduct of those maps:

$$\begin{array}{ccc}
\mathcal{B} \coprod \mathcal{B} & \xrightarrow{v} & \mathcal{B} \\
\downarrow^k & \downarrow & \downarrow^\iiota \\
C \coprod C' & \xrightarrow{r} & C \coprod C' \\
\downarrow^i & \downarrow & \downarrow^r \\
\mathcal{D} \coprod \mathcal{D}' & \xrightarrow{\Pi_\mathcal{B}} & \mathcal{D} \coprod \mathcal{D}'
\end{array}$$

so we may replace these pushouts of collages of projective cells in the cell complex presentation for $\text{coll}(\alpha): \text{coll}V \hookrightarrow \text{coll}W$ by the corresponding coproducts of collages of projective cells. Hence, the simplicial functor $\text{coll}(\alpha): \text{coll}V \hookrightarrow \text{coll}W$ can be understood as a countable composite of pushouts of coproducts of $\text{coll}(\partial \Delta[n] \times \mathcal{A}(a,-)) \hookrightarrow \text{coll}(\Delta[n] \times \mathcal{A}(a,-))$ in $sSet\text{-Cat}$.

²The **homotopy category** of a simplicially enriched category is defined by applying the path components functor $\pi_0: sSet \to Set$ to the hom-spaces. In fact, by the local homotopically fully faithfulness property, it suffices to assume essential surjectivity on homotopy categories.
This is advantageous because the inclusion below-left defines the action on non-trivial homs of a pushout square in \( sSet-Cat \) below-right whose horizontals send the two objects \(-\) and \(+\) to \( T \) and \( a \).

\[
\begin{align*}
\partial\Delta[n] &\xrightarrow{id_a} \partial\Delta[n] \times \mathcal{A}(a, a) \\
\Delta[n] &\xrightarrow{id_a} \Delta[n] \times \mathcal{A}(a, a) \\
2[\partial\Delta[n]] &\xrightarrow{\text{coll}\,(\partial\Delta[n] \times \mathcal{A}(a, -))} \text{coll}(\partial\Delta[n] \times \mathcal{A}(a, -)) \\
2[\Delta[n]] &\xrightarrow{\text{coll}(\Delta[n] \times \mathcal{A}(a, -))} \text{coll}(\Delta[n] \times \mathcal{A}(a, -))
\end{align*}
\]

\[ (6.2.15) \]

To see that \( \text{coll}(\partial\Delta[n] \times \mathcal{A}(a, -)) \hookrightarrow \text{coll}(\Delta[n] \times \mathcal{A}(a, -)) \) is a pushout of \( 2[\partial\Delta[n]] \hookrightarrow 2[\Delta[n]] \), transpose across the adjunction of Proposition 6.2.9 and apply the Yoneda lemma. Hence, the map \( \text{coll}(a) : \text{coll}V \hookrightarrow \text{coll}W \) is a countable composite of pushouts of coproducts of simplicial functors \( 2[\partial\Delta[n]] \hookrightarrow 2[\Delta[n]] \), which proves that this map is a relative simplicial computad.

Conversely, if \( \text{coll}(a) : \text{coll}V \hookrightarrow \text{coll}W \) is a relative simplicial computad, then it can be presented as a countable composite of pushouts of coproducts of simplicial functors \( 2[\partial\Delta[n]] \hookrightarrow 2[\Delta[n]] \); since this inclusion is bijective on objects the inclusion \( \emptyset \hookrightarrow 1 \) is not needed. Since the only arrows of \( \text{coll}W \) that are not present in \( \text{coll}V \) have domain \( T \) and codomain \( a \in \mathcal{A} \), the characterization of the essential image of the collage functor of Proposition 6.2.9(i) allows us to identify each stage of the countable composite

\[
\text{coll}V \hookrightarrow \text{coll}(W^1) \hookrightarrow \cdots \hookrightarrow \text{coll}(W^i) \hookrightarrow \text{coll}(W^{i+1}) \hookrightarrow \cdots \hookrightarrow \text{coll}W
\]

as the collage of some weight \( W^i : \mathcal{A} \to sSet \). Each attaching map \( 2[\partial\Delta[n]] \to \text{coll}W^i \) in the cell complex presentation acts on objects by mapping \(-\) and \(+\) to \( T \) and \( a \), respectively, for some \( a \in \mathcal{A} \).

The action on the non-trivial hom then defines a simplicial map \( \partial\Delta[n] \to W^i(a) \), which then defines a simplicial natural transformation \( \partial\Delta[n] \times \mathcal{A}(a, -) \to W^i \), which gives a factorization of the attaching map \( 2[\partial\Delta[n]] \to \text{coll}W^i \) through the top horizontal of the pushout square (6.2.15). Hence, the inclusion \( \text{coll}(W^i) \hookrightarrow \text{coll}(W^{i+1}) \) is a pushout of a coproduct of the maps \( \text{coll}(\partial\Delta[n] \times \mathcal{A}(a, -)) \hookrightarrow \text{coll}(\Delta[n] \times \mathcal{A}(a, -)) \), one for each cell \( 2[\partial\Delta[n]] \hookrightarrow 2[\Delta[n]] \) whose attaching map sends \(+\) to \( a \in \text{coll}(W^i) \).

We have now expressed \( \text{coll}(a) : \text{coll}V \hookrightarrow \text{coll}W \) as a countable composite of pushouts of coproducts of simplicial functors \( \text{coll}(\partial\Delta[n] \times \mathcal{A}(a, -)) \hookrightarrow \text{coll}(\Delta[n] \times \mathcal{A}(a, -)) \). A fully faithful functor that preserves colimits also reflects them, so in this way we see that \( a : V \hookrightarrow W \) is a countable composite of pushouts of coproducts of projective cells, proving that it is a projective cell complex as claimed. \( \square \)

\[ 6.2.16. \text{Example (the collage of the conical pullback).} \]

Let \( \Downarrow \) denote the cospan category \( c \to a \leftarrow b \).

The collage of the conical weight \( * : \Downarrow \to sSet \) is the 1-category with four objects and five non-identity 0-arrows as displayed

\[
\begin{array}{ccc}
\top & \xrightarrow{} & b \\
\downarrow & & \downarrow \\
c & \xleftarrow{} & a
\end{array}
\]

regarded as a constant simplicial category. The subcategory \( 1+ \Downarrow \) is free and hence defines a simplicial computad, as defined in Digression 6.2.12. However, because the square commutes, the collage of the conical weight is not free and hence does not define a simplicial computad. Hence the inclusion is not a relative simplicial computad and so by Theorem 6.2.14, the weight for the conical pullback is not flexible.
In this text, we have resisted a lengthy digression through homotopy coherent category theory, as those results are not needed here; see [104, 107]. Nonetheless, we cannot resist mentioning the following example.

6.2.17. **Example** ([107, §4]). The left adjoint \( \mathcal{C} : \mathbf{sSet} \to \mathbf{sSet-Cat} \) to the homotopy coherent nerve functor of Cordier [29], which we call *homotopy coherent realization*, carries monomorphisms of simplicial sets to relative simplicial computads (in fact, to simplicial subcomputad inclusions; see Digression 6.2.12). In particular, the coherent realization of the canonical inclusion \( \mathbf{1} + X \hookrightarrow X^d \) defines a collage and relative simplicial computad \( \mathbf{1} + \mathcal{C}X \hookrightarrow \mathcal{C}(X^d) \) and hence a flexible weight \( W_X \) for homotopy coherent diagrams of shape \( X \). Since the left adjoint of the collage adjunction is fully faithful, its unit is an isomorphism, and this permits us to define the weight \( W_X \) explicitly: for a vertex \( x \in X \),

\[
W_X(x) := \mathcal{C}(X^d)(\top, x).
\]

For homotopy coherent diagrams valued in Kan complex enriched categories, the weight \( W_X : \mathcal{C}X \to \mathbf{sSet} \) can be used to define the *pseudo limit* of a homotopy coherent diagram of shape \( X \). For homotopy coherent diagrams valued in quasi-categorically enriched categories, such as \( \infty \)-cosmoi, the weight \( W_X \) defines the *oplax limit*, since in that context the 1-arrows of \( \mathcal{C}(X^d) \) will likely map to non-invertible morphisms.

**Exercises.**

6.2.i. **Exercise.** Compute the collage of the weight \( U : \mathbf{1} \to \mathbf{sSet} \) and use Theorem 6.2.14 to give a second proof that simplicial cotensors are flexible weighted limits. Compare this argument with that given in Example 6.2.3.

6.2.ii. **Exercise.** Use Theorem 6.2.14 to verify that conical products are flexible weighted limits.

6.2.iii. **Exercise.** Compute the collage of the conical weight \( * : \omega^{op} \to \mathbf{sSet} \) for countable inverse limits and use Theorem 6.2.14 to verify that this weight is not flexible.

### 6.3. Homotopical Properties of Flexible Weighed Limits

Our interest in flexible weights stems from their homotopical properties, which we now explore. In a \( \mathcal{V} \)-model category \( \mathcal{M} \), the fibrant objects are closed under weighted limits whose weights are projective cofibrant; see Corollary C.3.15. For instance, the fibrant objects in a \( \mathbf{Cat} \)-enriched model structure are closed under flexible weighted limits [70, 5.4] in the sense of [17]. As explained in §E.1, \( \infty \)-cosmoi are very closely related to categories of fibrant objects associated to a model category that is enriched over the Joyal model structure on simplicial sets. Thus, we may adapt the proofs of results from enriched model category theory to obtain the following:

6.3.1. **Proposition (flexible weights are homotopical).** Let \( W : \mathcal{A} \to \mathbf{sSet} \) be a flexible weight and let \( \mathcal{K} \) be an \( \infty \)-cosmos.

(i) The weighted limit \( \lim_W F \) of any diagram \( F : \mathcal{A} \to \mathcal{K} \) may be expressed as a countable inverse limit of pullbacks of products of isofibrations

\[
\begin{array}{ccc}
F \Delta[\mathbf{n}] & \longrightarrow & F \delta[\Delta[\mathbf{n}]] \\
\end{array}
\]

one for each projective \( n \)-cell at \( a \) in the given projective cell complex presentation of \( W \). Hence, \( \infty \)-cosmoi admit all flexible weighted limits and cosmological functors preserve them.
(ii) If \( V \hookrightarrow W \in s\text{Set}^A \) is a projective cell complex between flexible weights, then for any diagram \( F: A \to \mathcal{K} \), the induced map between weighted limits
\[
\lim_W F \twoheadrightarrow \lim_V F
\]
is an isofibration.

(iii) If \( \alpha: F \Rightarrow G \) is a simplicial natural transformation between a pair of diagrams \( F, G: A \to \mathcal{K} \) whose components \( \alpha_a: F_a \Rightarrow G_a \) are isofibration, trivial fibrations, equivalences, then the induced map
\[
\lim_W F \xrightarrow{\alpha} \lim_W G
\]
is an isofibration, trivial fibration, or equivalence, respectively

**Proof.** To begin, observe that the axioms of Definition A.6.1 imply that the limit of a diagram \( F \) weighted by the weight \( U \times A(a, -) \), for \( U \in s\text{Set} \) and \( a \in A \), is the cotensor \( F_a^U \). Consequently, the map of weighted limits induced by the projective \( n \)-cell at \( a \) is the isofibration (6.3.2). By definition, any flexible weight is built as a countable composite of pushouts of coproducts of these projective cells and the weighted limit functor \( \lim_w \) carries each of these conical colimits to the corresponding limit notion. So it follows that \( \lim_w F \) may be expressed as a countable inverse limit of pullbacks of products of the maps (6.3.2). This proves (i).

The same argument proves (ii). By definition, a relative cell complex \( V \hookrightarrow W \) is built as a countable composite of pushouts of coproducts of these projective cells and the weighted limit functor \( \lim_w \) carries each of these conical colimits to the corresponding limit notion. So it follows that \( \lim_w F \) is the limit of a countable tower of isofibrations whose base is \( \lim_v F \), where each of these isofibrations is the pullback of products of the maps (6.3.2) appearing in the projective cell complex decomposition of \( V \hookrightarrow W \). As products, pullbacks, and limits of towers of isofibrations are isofibrations, (ii) follows.

For (iii), suppose first that \( \alpha \) is a componentwise isofibration. Then the simplicial natural transformation \( \alpha: F \Rightarrow G \) defines a simplicial functor \( A: A \to \mathcal{K}^\bullet \) valued in the \( \infty \)-cosmos of isofibrations of Proposition 6.1.1. By (i), this diagram admits a \( W \)-weighted limit \( \lim W A \), which is then necessarily an isofibration. Since the domain and codomain functors \( \text{dom}, \text{cod}: \mathcal{K} \to \mathcal{K} \) are cosmological, it is clear that the isofibration \( \lim W A \) coincides with the induced map on weighted limits \( \alpha: \lim W F \twoheadrightarrow \lim W G \).

If \( \alpha \) is a componentwise trivial fibration, then the above diagram and thus its \( W \)-weighted limit lies in the sub \( \infty \)-cosmos \( \mathcal{K}^\bullet \hookrightarrow \mathcal{K}^\bullet \) of trivial fibrations established in Proposition 6.1.5. By the analogous argument, we see that the induced map \( \alpha: \lim W F \Rightarrow \lim W G \) is a trivial fibration in this case. The final statement for equivalences now follows from the first two statements by Ken Brown’s Lemma C.1.10.

Proposition 6.3.1(i) proves that the flexible weighted limit of any diagram in an \( \infty \)-cosmos can be constructed out of the limits of diagrams of isofibrations axiomatized in 1.2.1(i). Our aim is now to describe a converse of sorts, constructing each of the limits listed there as instances of flexible weighted limits over a series of lemmas. It will follow that any quasi-categorically enriched category equipped with a class of representably-defined isofibrations that possesses flexible weighted limits will admit all of the simplicial limits of 1.2.1(i). This will help us identify new examples of \( \infty \)-cosmoi.

To start, simplicial cotensors are flexible weighted limits, as discussed in Example 6.2.3. This leaves only the conical limits: products, pullbacks of isofibrations, and inverse limits of towers of isofibrations. Example 6.2.4 notes that the weights for products are flexible. However, for the reasons discussed in
6.2.5, the weights for conical pullbacks or limits of towers of isofibrations are not flexible because the
definition of a cone over either diagram shape imposes composition relations on 0-arrows.

Our strategy is to modify the weights for pullbacks and for limits of countable towers so that each
composition equation involved in defining cones over such diagrams is replaced by the insertion of an
"invertible" arrow one dimension up, where we must also take care to define this "invertibility" without
specifying any equations between arrows in the next dimension. We have a device for specifying just
this sort of isomorphism: recall the homotopy coherent isomorphism $\mathbb{I}$ from Exercise 1.1.v(i). A diagram
$\mathbb{I} \to \text{Fun}(A, B)$ specifies a "homotopy coherent isomorphism" between a pair of 0-arrows $f$ and $g$ from
$A$ to $B$, given by:

- a pair of 1-arrows $\alpha : f \to g$ and $\beta : g \to f$,
- a pair of 2-arrows

$$
\begin{array}{ccc}
\Phi & f & \beta \\
\downarrow & \Phi & \downarrow \\
\beta & f & \alpha
\end{array}
$$

- a pair of 3-arrows whose outer faces are $\Phi$ and $\Psi$ and whose inner faces are degenerate,
- a pair of 4-simplices whose outer faces are these 3-simplices and whose inner faces are degenerate,

and so on.

We now introduce the weight for pullback diagrams whose cone shapes are given by squares
inhabited by a homotopy coherent isomorphism.

6.3.3. DEFINITION (iso-commas). The **iso-comma object** $C \times B$ of a cospan

$$
C \xymatrix{ & A \ar[l]_g \ar[r]^f & B
}
$$
in a simplicially enriched and cotensored category is the limit weighted by a weight $W_\mathcal{X} : \mathfrak{S} \to s\mathcal{S}et$
defined by the cospan

$$
\mathbb{I} \xymatrix{ & \mathbb{I} \ar[l]_1 \ar[r]^0 & \mathbb{I}
}
$$

Under the simplification of Remark A.6.11, the formula for the weighted limit reduces to the equalizer
of the pair of maps

$$
\begin{array}{c}
C \times A^\mathbb{I} \times B \ar[r]_\pi & A^\mathbb{I} \times B \ar[r]^{(q_1, q_0)} & A \times A
\end{array}
$$

where the maps $(q_1, q_0) : A^\mathbb{I} \to A \times A$ are defined by restricting along the endpoint inclusion
$\mathbb{I} + \mathbb{I} = \partial \mathbb{I} \hookrightarrow \mathbb{I}$. In an $\infty$-cosmos, this map is an isofibration and the equalizer defining the iso-comma
object is computed by the pullback

$$
\begin{array}{c}
C \times B \ar[r]_g \ar[d]^{(q_1, q_0)} & A^\mathbb{I} \ar[d]^{(q_1, q_0)} \\
C \times B \ar[r]_{g \times f} & A \times A
\end{array}
$$

6.3.5. LEMMA. *Iso-comma objects are flexible weighted limits and in particular exist in any $\infty$-cosmos.*
PROOF. Reprising the notation for the objects in the cospan category \( \mathfrak{A} \) used in Example 6.2.16, the weight \( W_\mathfrak{A} \) is constructed by the pushout

\[
\partial \mathbb{I} \times \mathfrak{A}(a, -) \to \mathfrak{A}(b, -) \sqcup \mathfrak{A}(c, -) \to W_\mathfrak{A}
\]

where the attaching map picks out the two arrows in the cospan \( \mathfrak{A} \). As a projective cell complex, \( W_\mathfrak{A} \) is built from a projective 0-cell at \( b \), a projective 0-cell at \( c \), and two projective \( k \)-cells at \( a \) for each \( k > 0 \), corresponding to the non-degenerate simplices of \( \mathbb{I} \). As described by Remark 6.2.2, these may be attached all at once. In this way, we see that \( W_\mathfrak{A} \) is a flexible weight, so Proposition 6.3.1(i) tells us that iso-comma objects exist in any \( \infty \)-cosmos, a fact that is also evident from the pullback (6.3.4).

6.3.6. REMARK. In the homotopy 2-category of an \( \infty \)-cosmos, there is a canonical invertible 2-cell defining the iso-comma cone:

\[
\begin{array}{ccc}
C \times B & \xrightarrow{q_0} & B \\
\downarrow{\phi} & & \downarrow{f} \\
C & \xrightarrow{g} & A
\end{array}
\]

that has a weak universal property analogous to that of the comma cone presented in Proposition 3.4.6; see [106, §3]. The proof, like the proof of that result, makes use of the fact that \( A\mathbb{I} \) is the weak \( \mathbb{I} \)-cotensor in the homotopy 2-category [103, 3.3.13]. The proof of this fact is somewhat delicate, making use of marked simplicial sets as appeared already in the proof of Corollary 1.1.16, which gives 1-cell induction.

Our notation for iso-commas is deliberately similar to the usual notation for pullbacks. In an \( \infty \)-cosmos, iso-commas can be used to compute “homotopy pullbacks” of diagrams in which neither map is an isofibration. When at least one map of the cospan is an isofibration, the iso-comma is equivalent to the conical pullback.

6.3.7. LEMMA (iso-commas and pullbacks). In an \( \infty \)-cosmos \( \mathcal{K} \), pullbacks and iso-commas of cospans in which at least one map is an isofibration are equivalent. More precisely, given a pullback square as below-left and an iso-comma square as below-right

\[
\begin{array}{ccc}
P & \xrightarrow{b} & B \\
\downarrow{c} & & \downarrow{f} \\
C & \xrightarrow{g} & A
\end{array}
\quad \quad \quad \quad \quad \quad
\begin{array}{ccc}
C \times B & \xrightarrow{q_0} & B \\
\downarrow{\phi} & & \downarrow{f} \\
C & \xrightarrow{g} & A
\end{array}
\]

\( P \simeq C \times B \) over \( C \) and up to isomorphism over \( B \).

PROOF. Applying Lemma 1.2.16 to the functor \( b : P \to B \), we can replace the span \((c, b) : P \to C \times B \) by a span \((c, p) : Pb \to C \times B \) whose legs are both isofibrations that is related via an equivalence \( s : P \Rightarrow Pb \) that lies over \( C \) on the nose and over \( B \) up to isomorphism. We will show that under the hypothesis that \( f \) is an isofibration, this new span is equivalent to the iso-comma span.
To see this, note that the factorization constructed in (1.2.17) is in fact defined using an iso-comma, constructed via the pullback in the top square of the diagram below-left. Since the map $b$ is itself defined by a pullback, the bottom square of the diagram below-left is also a pullback, defining the left-hand pullback rectangle:

\[
\begin{array}{c}
P_b \\ (q,p) \downarrow & \searrow \downarrow \mathbb{I} \\
P \times B & \xrightarrow{b \times B} & B \times B \\
\downarrow c \times B & \searrow f \times B & \downarrow \\
C \times B & \xrightarrow{g \times B} & A \times B
\end{array}
\]

Now the iso-comma is constructed by a similar pullback rectangle, displayed above-right. And because $f$ is an isofibration, Lemma 1.2.14 tells us that the Leibniz tensor $i_0 \wedge f : B \Rightarrow A \times I$ is a trivial fibration. This equivalence commutes with the projections to $A \times B$ and hence the maps $(c q, p) : P_b \Rightarrow C \times B$ and $(q_1, q_0) : C_A \times B \Rightarrow C_A \times B$, defined as pullbacks of an equivalent pair of isofibrations along $g \times B$, are equivalent as claimed. □

We now introduce a flexible weight for diagrams given by a countable tower of 0-arrows whose cone shapes will have a homotopy coherent isomorphism in the triangle over each generating arrow in the diagram.

6.3.8. Definition (iso-towers). Recall the category $\omega$ whose objects are natural numbers and whose morphisms are freely generated by maps $i_{n,n+1} : n \to n + 1$ for each $n$. The iso-tower of a $\omega^\text{op}$-shaped diagram

\[
F := \cdots \xrightarrow{f_{n+2,n+1}} F_{n+1} \xrightarrow{f_{n+1,n}} F_n \xrightarrow{f_{n,n-1}} \cdots \xrightarrow{f_{2,1}} F_1 \xrightarrow{f_{1,0}} F_0
\]

in a simplicially enriched and cotensored category is the limit weighted by the diagram $W^\psi : \omega^\text{op} \to s\text{Set}$ defined by the pushout

\[
\begin{array}{c}
\prod_{n \in \omega} \partial I \times \omega(-, n) \xrightarrow{(id_{n+1}, n+1)} \prod_{n \in \omega} \omega(-, n) \\
\downarrow & \searrow \downarrow \\
\prod_{n \in \omega} I \times \omega(-, n) & \xrightarrow{\psi} & W^\psi
\end{array}
\]

in $s\text{Set}^\omega$.

By Definition A.6.1(ii), in an $\infty$-cosmos the iso-tower of $F$ is constructed by the pullback

\[
\begin{array}{c}
\lim_{W^\psi} F \\ \phi \downarrow & \searrow \downarrow \\
\prod_{n \in \omega} F_n \xrightarrow{\psi} & \prod_{n \in \omega} F^\psi_n \\
\downarrow & \searrow \downarrow \mathbb{I}(q_1, q_0) \\
\prod_{m \in \omega} F_m \xrightarrow{(f_{n+1,n}, id_n, f_n)} & \prod_{n \in \omega} F_n \times F_n
\end{array}
\]

216
The limit cone is generated by a 0-arrow $\rho_n : \lim_{\mathcal{W}} F \to F_n$ for each $n \in \omega$ together with a homotopy coherent isomorphism $\phi_n$ in each triangle over a generating arrow $F_{n+1} \to F_n$ in the $\omega^{op}$-indexed diagram.

6.3.11. Lemma. Iso-towers are flexible weighted limits and in particular exist in any $\infty$-cosmos.

Proof. The weight $\mathcal{W}^{\to}$ is a projective cell complex built by attaching one projective 0-cell at each $n \in \omega$ — forming the coproduct appearing in the upper right-hand corner of (6.3.9) — and then by attaching a projective $k$-cell at each $n \in \omega$ for each non-degenerate $k$-simplex of $\mathbb{I}$ with $k > 0$. Rather than attach each projective $k$-cell for fixed $n \in \omega$ in sequence, by Remark 6.2.2 these can all be attached at once by taking a single pushout of the “generalized projective cell at $n$” defined by the map $\partial \mathbb{I} \times \omega(-, n) \hookrightarrow \mathbb{I} \times \omega(-, n)$. These are the maps appearing as the left-hand vertical of (6.3.9). Now Proposition 6.3.1(i) or the formula (6.3.10) make it clear that such objects exist in any $\infty$-cosmos. □

As is the case for iso-commas and pullbacks, isotowers give a way to compute inverse limits of diagrams of arbitrary maps. When those maps are isofibrations, the isotower is equivalent to the conical limit.

6.3.12. Lemma (iso-towers and inverse limits). In an $\infty$-cosmos $\mathcal{K}$, the inverse limit of a countable tower of isofibrations is equivalent to the iso-pullback of that tower.

Proof. We will rearrange the formula (6.3.10) to construct the iso-tower $\lim_{\mathcal{W}} F$ as an inverse limit of a countable tower of isofibrations $P : \omega^{op} \to \mathcal{K}$ that is pointwise equivalent to the diagram $F : \omega^{op} \to \mathcal{K}$. In the case where the diagram $F$ is also given by a tower of isofibrations

$$
\begin{array}{ccccccccc}
\lim P & 
\cong 
& & & & & & & & \\
\downarrow & & & & & & & & & \\
\lim F & 
\cong 
& & & & & & & & \\
\end{array}
$$

the equivalence invariance of the inverse limit of a diagram of isofibrations will imply that the limits $\lim_{\mathcal{W}} F \cong \lim P$ and $\lim F$ are equivalent as claimed. The $\infty$-categories $P_n$ will be defined as conical limits of truncated versions of the diagram (6.3.10). To start define $P_0 := F_0$ and $e_0$ to be the identity, then define $P_1, p_{1,0}$, and $e_1$ via the pullback

$$
\begin{array}{ccc}
P_1 & \xrightarrow{p_{1,0}} & F_0 \\
\downarrow & & \downarrow q_0 \\
F_1 & \xrightarrow{f_{1,0}} & F_0 \\
\end{array}
$$

Note that $P_1 \cong F_1 \times F_0$ computes the iso-comma objects of the cospan given by $\text{id}_{F_0}$ and $f_{1,0}$.
Now define $P_2, p_{2,1}$, and $e_2$ using the composite pullback

$$
\begin{array}{ccccccc}
P_2 & \xrightarrow{p_{2,1}} & P_1 & \xrightarrow{e_1} & P_1^I_0 & \xrightarrow{q_0} & F_0 \\
\downarrow & & \downarrow & & \downarrow & & \\
P_2^I & \xrightarrow{q_0} & F_1 & \xrightarrow{f_{1,0}} & F_0 \\
\end{array}
$$

Continuing inductively, $P_n, p_{n,n-1}$, and $e_n$ are defined by appending the diagram

$$
\begin{array}{ccccccc}
P_n & \xrightarrow{e_{n+1,n}} & P_{n+1} & \xrightarrow{e_{n+1}} & P_{n+1}^I_0 & \xrightarrow{q_0} & F_n \\
\downarrow & & \downarrow & & \downarrow & & \\
P_n^I & \xrightarrow{q_0} & F_{n+1} & \xrightarrow{f_{1,0}} & F_n \\
\end{array}
$$

to the limit cone defining $P_{n-1}$ and taking the limit of this composite diagram. In the limit, the composite diagram is an unraveling of (6.3.10). Hence $\lim W F \cong \lim P$.

It remains to use the maps $e_n : P_n \Rightarrow F_n$ to compare $\lim P$ with $\lim F$. There is one small problem with the construction just given: it defines a diagram (6.3.13) in which each square commutes up to isomorphism — the isomorphism encoded by the map $P_n \rightarrow F_n^I$ — not on the nose. But because the maps $f_{n+1,n}$ are isofibrations this is no problem. The isomorphism inhabiting the square $e_0 p_{1,0} \cong f_{1,0} e_1$ can be lifted along $f_{1,0}$ to define a new map $e'_1 : P_1 \Rightarrow F_1$ isomorphic to $e_1$. By Exercise 1.4.iv this $e'_1$ is then also an equivalence (though no longer necessarily a trivial fibration), so we replace $e_1$ with $e'_1$, and then continue inductively to lift away the isomorphisms in the square $e'_1 p_{2,1} \cong f_{2,1} e_2$.

Since inverse limits of towers of isofibrations are equivalence-invariant by Proposition C.1.15, it follows that $\lim P \cong \lim F$. By construction $\lim P \cong \lim W F$, so it follows that $\lim W F \cong \lim F$, which is what we wanted to show. \qed

**Exercises.**

6.3.i. Exercise ([108, 2.2.2]). Show that $\infty$-cosmoi admit **wide pullbacks**: limits of finite or countable diagrams of the following form

$$
\begin{array}{ccccccc}
\ldots & A_n & \xrightarrow{p_{n-1}} & A_{n-1} & \xrightarrow{p_{n-2}} & \ldots & A_1 & A_0 \\
\ldots & B_{n-1} & \xrightarrow{f_{n-1}} & B_{n-2} & \xrightarrow{f_{n-2}} & \ldots & B_1 & B_0 \\
\end{array}
$$

and that their construction is invariant under pointwise equivalence between diagrams.

**6.4. Cosmologically Embedded $\infty$-Cosmoi**

In this section, we generalize Lemma 6.1.4—which was used to show that the subcategory of discrete $\infty$-categories inherits an $\infty$-cosmos structure—to subcategories of $\infty$-cosmoi that are not full. As we shall discover, there are many interesting examples.
For any ∞-cosmos $\mathcal{K}$ and any subcategory of its underlying 1-category — that is for any subset of its objects and subcategory of its 0-arrows — one can form a quasi-categorically enriched subcategory $\mathcal{L} \subset \mathcal{K}$ that contains exactly those objects and 0-arrows and all higher dimensional arrows that they span. We call such subcategories **full on positive-dimensional arrows**; note the functor spaces of $\mathcal{L}$ are quasi-categories because all inner horn inclusions are bijective on vertices. We will take particular interest in subcategories that satisfy a further “repleteness” condition.

6.4.1. **Definition.** Let $\mathcal{K}$ be an ∞-cosmos. A subcategory $\mathcal{L} \subset \mathcal{K}$ is **replete** in $\mathcal{K}$ if it is full on positive-dimensional arrows and moreover:

(i) Every ∞-category in $\mathcal{K}$ that is equivalent to an object in $\mathcal{L}$ lies in $\mathcal{L}$.
(ii) Any equivalence in $\mathcal{K}$ between objects in $\mathcal{L}$ lies in $\mathcal{L}$.
(iii) Any 0-arrow in $\mathcal{K}$ that is isomorphic in $\mathcal{K}$ to an 0-arrow in $\mathcal{L}$ lies in $\mathcal{L}$.

The inclusion of a replete subcategory of an ∞-cosmos is both a monomorphism and also an isofibration of quasi-categorically enriched categories, in a sense explored in Exercise 6.4.i.

6.4.2. **Lemma.** Suppose $\mathcal{L} \subset \mathcal{K}$ is a replete subcategory of an ∞-cosmos. Then any map $p: E \rightarrow B$ in $\mathcal{L}$ that defines an isofibration in $\mathcal{K}$ is a representably-defined isofibration in $\mathcal{L}$: that is for all $X \in \mathcal{L}$, $p_*: \text{Fun}_\mathcal{L}(X, E) \rightarrow \text{Fun}_\mathcal{L}(X, B)$ is an isofibration of quasi-categories.

**Proof.** Since $\mathcal{K}$ is an ∞-cosmos, axiom 1.2.1(ii) requires that $p_*: \text{Fun}_\mathcal{K}(X, E) \rightarrow \text{Fun}_\mathcal{K}(X, B)$ is an isofibration of quasi-categories. Because the inner horn inclusions are bijective on positive-dimensional arrows, it follows immediately that the restricted map $p_*: \text{Fun}_\mathcal{L}(X, E) \rightarrow \text{Fun}_\mathcal{L}(X, B)$ lifts against the inner horn inclusions. Thus it remains only to solve lifting problems of the form displayed below-left

\[
\begin{array}{ccc}
1 & \xrightarrow{e} & \text{Fun}_\mathcal{L}(X, E) \\
\downarrow & & \downarrow \text{Fun}_\mathcal{K}(X, E) \\
1 & \xrightarrow{\beta} & \text{Fun}_\mathcal{L}(X, B) \\
\end{array}
\]

The lifting problem defines a 0-arrow $e: X \rightarrow E$ in $\mathcal{L}$ and an isomorphism $\beta: b \cong pe$ in $\mathcal{L}$. Its solution in $\mathcal{K}$ defines a 0-arrow $e': X \rightarrow E$ in $\mathcal{K}$ so that $pe' = b$ together with an isomorphism $e \cong e'$ in $\mathcal{K}$. By fullness on positive-dimensional arrows, to show that this lift factors through the inclusion $\text{Fun}_\mathcal{L}(X, E) \hookrightarrow \text{Fun}_\mathcal{K}(X, E)$, we need only argue that the map $e'$ lies in $\mathcal{L}$, but this is the case by condition (iii) of Definition 6.4.1. □

The following result describes a condition under which a replete subcategory $\mathcal{L} \subset \mathcal{K}$ inherits an ∞-cosmos structure created from $\mathcal{K}$.

6.4.3. **Proposition.** Suppose $\mathcal{L} \subset \mathcal{K}$ is a replete subcategory of an ∞-cosmos. If $\mathcal{L}$ is closed under flexible weighted limits in $\mathcal{K}$, then $\mathcal{L}$ defines an ∞-cosmos with isofibrations, equivalences, trivial fibrations and simplicial limits created by the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$, which then defines a cosmological functor.

When these conditions hold, we refer to $\mathcal{L}$ as a **cosmologically embedded** ∞-cosmos of $\mathcal{K}$ and $\mathcal{L} \hookrightarrow \mathcal{K}$ as a **cosmological embedding**. The notation reflects both the embedding and isofibration-like properties of replete subcategory inclusions.

**Proof.** To say that a replete subcategory $\mathcal{L} \hookrightarrow \mathcal{K}$ is closed under flexible weighted limits means that for any diagram in $\mathcal{L}$ and any limit cone in $\mathcal{K}$ over that diagram, then the limit cone lies in $\mathcal{L}$ and
satisfies the appropriate simplicially-enriched universal property of Definition A.6.5 in the subcategory \( \mathcal{L} \). We must verify that each of the limits of axiom 1.2.1(i) exist in \( \mathcal{L} \). Immediately, \( \mathcal{L} \) has a terminal object, products, and simplicial cotensors, since all of these are flexible weighted limits. By Lemmas 6.3.5 and 6.3.11, \( \mathcal{L} \) also admits the construction of iso-comma objects and of iso-towers.

Define the class of isofibrations in \( \mathcal{L} \) to be those maps in \( \mathcal{L} \) that define isofibrations in \( \mathcal{K} \). By Lemmas 6.3.7 and 6.3.12, pullbacks and limits of towers of isofibrations are equivalent in \( \mathcal{K} \) to the iso-commas and iso-towers formed over the same diagrams. Since these latter limit cones lie in \( \mathcal{L} \) by hypothesis, so do the equivalent former cones by repleteness of \( \mathcal{L} \) in \( \mathcal{K} \).

There is a little more still to verify: namely that pullbacks and limits of towers of isofibrations satisfy the simplicially-enriched universal property as conical limits in \( \mathcal{L} \). In the case of a pullback diagram

\[
\begin{array}{ccc}
P & \xrightarrow{h} & B \\
\downarrow{k} & & \downarrow{f} \\
C & \xrightarrow{g} & A
\end{array}
\]

in \( \mathcal{L} \) we must show that for each \( X \in \mathcal{L} \), the functor space \( \text{Fun}_\mathcal{L}(X, P) \) is isomorphic to the pullback \( \text{Fun}_\mathcal{L}(X, C) \times_{\text{Fun}_\mathcal{L}(X, A)} \text{Fun}_\mathcal{L}(X, B) \) of functor spaces. We have such an isomorphism for functor spaces in \( \mathcal{K} \) and on account of the commutative diagram

\[
\begin{array}{ccc}
\text{Fun}_\mathcal{L}(X, P) & \xrightarrow{\approx} & \text{Fun}_\mathcal{K}(X, P) \\
\downarrow & & \downarrow \\
\text{Fun}_\mathcal{L}(X, C) \times \text{Fun}_\mathcal{L}(X, B) & \xrightarrow{\approx} & \text{Fun}_\mathcal{K}(X, C) \times \text{Fun}_\mathcal{K}(X, B)
\end{array}
\]

and fullness on positive-dimensional arrows, we need only verify surjectivity of the dotted map on 0-arrows. So consider a cone \((b \colon X \to B, c \colon X \to C)\) over the pullback diagram in \( \mathcal{L} \). By the universal property of the iso-comma \( C \times_A B \), there exists a factorization \( y \colon X \to C \times_A B \) in \( \mathcal{L} \). Composing with the equivalence \( C \times_B A \approx P \), this map is equivalent to the factorization \( z \colon X \to P \) of the cone \((b, c)\) through the limit cone \((h, k)\) in \( \mathcal{L} \) that exists on account of the strict universal property of the pullback in there. By repleteness, the isomorphism between \( z \) and the composite of \( y \) with the equivalence suffices to show that \( z \) lies in \( \mathcal{L} \). Hence, the functor spaces in \( \mathcal{L} \) are isomorphic. A similar argument invoking Lemma 6.3.12 proves that inverse limits of towers of isofibrations define conical limits in \( \mathcal{L} \). This completes the proof of the limit axiom 1.2.1(i).

Since the isofibrations in \( \mathcal{L} \) are a subset of the isofibrations in \( \mathcal{K} \) and the limit constructions in both contexts coincide, most of the closure properties of 1.2.1(ii) are inherited from the closure properties in \( \mathcal{K} \). The one exception is the requirement that the isofibrations in \( \mathcal{L} \) define isofibrations of quasi-categories representably, which was proven for any replete subcategory in Lemma 6.4.2. This proves that \( \mathcal{L} \) defines an \( \infty \)-cosmos.

Finally, we argue that the equivalences in \( \mathcal{L} \) are created from the equivalences of \( \mathcal{K} \), which will imply that the trivial fibrations in \( \mathcal{L} \) coincide with those of \( \mathcal{K} \) as well. Condition (ii) of Definition 6.4.1 implies that for any arrow in \( \mathcal{L} \) that defines an equivalence in \( \mathcal{K} \), its equivalence inverse and witnessing homotopies of Lemma 1.2.18 lie in \( \mathcal{L} \). Because we have already shown that \( \mathcal{L} \) admits cotensors with \( I \) preserved by the inclusion \( \mathcal{L} \hookrightarrow \mathcal{K} \), Lemma 1.2.18 implies that this data defines an equivalence in \( \mathcal{L} \). Conversely, any equivalence in \( \mathcal{L} \) extends to the data of (1.2.19) and since \( \mathcal{L} \hookrightarrow \mathcal{K} \) preserves
I-cotensors, this data defines an equivalence in $\mathcal{K}$. Thus, by construction, the $\infty$-cosmos structure of $\mathcal{L}$ is preserved and reflected by the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$ as claimed.

In practice, the repleteness condition of Definition 6.4.1 is satisfied by any subcategory of objects and 0-arrows that is characterized by some $\infty$-categorical property, so the main task in verifying that a subcategory defines an $\infty$-cosmos is verifying the closure under flexible weighted limits. In our first example, which acts as a sort of base case, we must do this by hand. In subsequent examples, we will deploy various techniques to bootstrap the flexible weighted limit closure from previously-established facts.

6.4.4. Proposition. For any $\infty$-cosmos $\mathcal{K}$, let $\mathcal{K}_\uparrow$ denote the quasi-categorically enriched category whose

(i) objects are $\infty$-categories in $\mathcal{K}$ that possess a terminal object and

(ii) functor spaces $\text{Fun}_\uparrow(A, B) \subset \text{Fun}(A, B)$ are the sub-quasi-categories whose 0-arrows preserve terminal objects and containing all $n$-arrows these functors span.

Then the inclusion $\mathcal{K}_\uparrow \hookrightarrow \mathcal{K}$ creates an $\infty$-cosmos structure on $\mathcal{K}_\uparrow$ from $\mathcal{K}$, and moreover for each object of $\mathcal{K}_\uparrow$ defined as a flexible weighted limit of some diagram in $\mathcal{K}_\uparrow$, its terminal element is created by the 0-arrow legs of the limit cone.

Proof. We apply Proposition 6.4.3. Lemma 2.2.7 and Proposition 2.1.10 verify the repleteness conditions, so it remains only to prove closure under flexible weighted limits. We do so by induction over the tower of isofibrations constructed in Proposition 6.3.1(i), which expresses a flexible weighted limit $\lim_W F$ as the inverse limit of a tower of isofibrations

$$\lim_W F \to \cdots \to \lim_{W_{k+1}} F \to \lim_{W_k} F \to \cdots \to \lim_{W_0} F \to 1$$

each of which is a pullback of products of maps of the form (6.3.2) indexed by the projective cells of the flexible weight $W$. We argue inductively that each $\infty$-category in this tower possesses a terminal element that is created by the legs of the tower of isofibrations.

For the base case, if $(A_i)_{i \in I}$ is a family of $\infty$-categories possessing terminal elements $t_i : 1 \to A_i$, then the product of the adjunctions $! \dashv t_i$ defines an adjunction

$$1 \cong \prod_{i \in I} 1 \perp \prod_{i \in I} A_i$$

exhibiting $(t_i)_{i \in I}$ as a terminal element of $\prod_{i \in I} A_i$. By construction, this terminal element is jointly created by the legs of the limit cone. Note that by construction the product-projection functors preserve this terminal element and the map into the product $\infty$-category $\prod_{i \in I} A_i$ induced by any family of terminal element preserving functors $(f : X \to A_i)_{i \in I}$ will preserve terminal elements. This verifies that the subcategory $\mathcal{K}_\uparrow$ is closed under products.

Similarly, if $A$ is an $\infty$-category with a terminal element $t : 1 \to A$, then by Proposition 2.1.7(iii), the constant diagram at $t$, which we also denote by $t$, defines a terminal element in the cotensor $A^U$ by any simplicial set $U$:

$$1 \cong 1^U \perp \prod_{i \in I} A^U$$
It remains to argue that terminal elements in $A^U$ are jointly created by the 0-arrow components of the limit cone, namely by evaluation on each of the vertices of the cotensoring simplicial set. To that end, suppose $s: 1 \to A^U$ has the property that

$$s_\mathbf{u} := 1 \xrightarrow{s} A^U \xrightarrow{ev_\mathbf{u}} A$$

is terminal in $A$ for each vertex $\mathbf{u}$ of $U$. By terminality of $t: 1 \to A^U$ there is a 1-arrow $\alpha: s \to t$, and since both $s_\mathbf{u}$ and $t$ define terminal elements of $A$, the component of $\alpha$ at each $\mathbf{u}$ defines an isomorphism $\alpha_{\mathbf{u}}: s_\mathbf{u} \to t$ in $A$. By Corollary 1.1.21, it follows that $\alpha$ is an isomorphism, which tells us that $s$ is also a terminal element of $A^U$.

For the inductive step consider a pullback diagram

$$
\begin{array}{c}
\lim W_{k+1} F & \longrightarrow & A^{\Delta[n]} \\
\downarrow \alpha & & \downarrow \\
\lim W_k F & \longrightarrow & A^{\partial \Delta[n]}
\end{array}
$$

that arises from the attaching map for a projective $n$-cell. The inductive hypothesis tells us that $\lim W_k F$ admits a terminal element $t_k$ and for each vertex of $i \in \partial \Delta[n]$, the corresponding component $\ell_i: \lim W_k F \to A$ of the limit cone preserves it. Since $F$ is a diagram valued in $K_T$ and $A$ is an $\infty$-category in its image, we know that $A$ must possess a terminal element $t: 1 \to A$. Thus the constant diagram $t: 1 \to A^{\partial \Delta[n]}$ defines a terminal element. By terminality, there is a 1-arrow $\alpha: \ell(t_k) \to t \in A^{\partial \Delta[n]}$ whose components at each $i \in \partial \Delta[n]$ are isomorphisms in $A$. By Corollary 1.1.21, it follows that $\alpha$ is also an isomorphism, which tells us that $\ell(t_k)$ is also a terminal element of $A^{\partial \Delta[n]}$. Thus, we see that $\ell$ preserves terminal elements. The proof is now completed by the following lemma:

6.4.5. **Lemma.** Consider a pullback diagram

$$
\begin{array}{c}
P & \xrightarrow{h} & B \\
\downarrow k & & \downarrow f \\
C & \xrightarrow{g} & A
\end{array}
$$

in which the $\infty$-categories $A$, $B$, and $C$ possess a terminal element and the functors $f$ and $g$ preserve them. Then $P$ possesses a terminal element that is created by the legs of the pullback cone $h$ and $k$.

**Proof.** If $b: 1 \to B$ and $c: 1 \to C$ are terminal, then uniqueness of terminal elements implies that $f(b) \cong g(c) \in A$. Using the fact that $f$ is an isofibration, there is a lift $b' \cong b$ of this isomorphism along $f$ that then defines another terminal element of $B$. The pair $(c, b')$ now induces an element $t$ of $P$ that we claim is terminal.

To see this, we apply Proposition 4.3.13, which proves that $t$ is a terminal element of $P$ if and only if the domain-projection functor $p_0: \text{Hom}_0(P, t) \to P$ is a trivial fibration. By construction of $t$, we know that the domain-projection functors for the elements $ht = b'$, $kt = c$, and $fht = gkt$ are all

222
trivial fibrations and moreover the top and bottom faces of the cube

\[
\begin{array}{ccc}
\text{Hom}_P(P, t) & \rightarrow & \text{Hom}_B(B, ht) \\
\downarrow & & \downarrow \\
\text{Hom}_C(C, kt) & \rightarrow & \text{Hom}_A(A, gkt) \\
\downarrow & & \downarrow \\
C & \rightarrow & A \\
\end{array}
\]

are pullbacks. By Proposition 3.3.3, the fact that the three maps between the cospans are equivalences implies that the map between their pullbacks is also an equivalence, as required.

Applying the result of Proposition 6.4.4 to \(\mathcal{K}^\circ\) constructs an \(\infty\)-cosmos \(\mathcal{K}_\perp\) whose objects are \(\infty\)-categories in \(\mathcal{K}\) that possess an initial object and whose 0-arrows are initial-element-preserving functors. It is straightforward to verify that the inclusion \(\mathcal{K}_\perp \hookrightarrow \mathcal{K}\) is a cosmological embedding. Combining these results, we get an \(\infty\)-cosmos for the pointed \(\infty\)-categories of Definition 4.4.1, those that possess a zero element.

6.4.6. PROPOSITION. For any \(\infty\)-cosmos \(\mathcal{K}\), let \(\mathcal{K}_\ast\) denote the quasi-categorically enriched category of pointed \(\infty\)-categories, i.e., \(\infty\)-categories that possess a zero element, and functors that preserve them. Then the inclusion \(\mathcal{K}_\ast \hookrightarrow \mathcal{K}\) is a cosmological embedding, creating an \(\infty\)-cosmos structure on \(\mathcal{K}_\ast\) from \(\mathcal{K}\), and moreover for each object of \(\mathcal{K}_\ast\) defined as a flexible weighted limit of some diagram in \(\mathcal{K}\), its zero element is created by the 0-arrow legs of the limit cone.

PROOF. This result follows directly from Proposition 6.4.4 and its dual, since the \(\infty\)-cosmos \(\mathcal{K}_\ast\) of \(\infty\)-categories in \(\mathcal{K}\) possessing a zero object is isomorphic to \((\mathcal{K}_\ast \perp) \cong (\mathcal{K}_\perp \ast)\), the insight being that an initial element \(a: 1 \rightarrow A\) in \(\mathcal{K}_\ast\) is encoded by a terminal-object preserving functor, which says exactly that \(a\) is a zero element in \(A\).

Applying the result of Proposition 6.4.4 or its dual to the \(\infty\)-cosmos \(\mathcal{K}/B\) of isofibrations over \(B \in \mathcal{K}\), we obtain two new \(\infty\)-cosmoi of interest.

6.4.7. COROLLARY. For any \(\infty\)-category \(B\) in an \(\infty\)-cosmos \(\mathcal{K}\), the sliced \(\infty\)-cosmos \(\mathcal{K}/B\) admits cosmologically embedded \(\infty\)-cosmoi

\[
\mathcal{Rari}(\mathcal{K})_B \hookrightarrow \mathcal{K}/B \hookleftarrow \mathcal{Lari}(\mathcal{K})_B
\]

whose

- objects are isofibrations over \(B\) admitting a right adjoint right inverse or left adjoint right inverse, respectively, and
- 0-arrows are functors over \(B\) that commute with the respective right or left adjoints up to fibered isomorphism over \(B\).

PROOF. By Corollary 3.6.9, these \(\infty\)-cosmoi are defined by

\[
\mathcal{Rari}(\mathcal{K})_B := (\mathcal{K}/B)^\ast \quad \text{and} \quad \mathcal{Lari}(\mathcal{K})_B := (\mathcal{K}/B)_{\perp}.
\]

Leveraging Corollary 6.4.7, we can establish similar cosmological embeddings

\[
\mathcal{Rari}(\mathcal{K}) \hookrightarrow \mathcal{K}^\ast \hookleftarrow \mathcal{Lari}(\mathcal{K})
\]
defining \(\infty\)-cosmoi of right adjoint right inverse or left adjoint right inverse adjunctions with varying bases. To apply Proposition 6.4.3, we must check closure under flexible weighted limits. We argue separately for cotensors, which are easy, and for the conical limits, which are harder—as the reader who attempted to solve Exercise 5.2.iv using Theorem 5.2.10(iii) may have already discovered. To treat all of the conical limits at once, we make use of a general 1-categorical result that constructs limits in the total space \(E\) of a Grothendieck fibration \(P: E \to B\) out of limits in the base \(B\) and limits in the fibers \(E_B\).

6.4.8. Lemma. Let \(P: E \to B\) be a Grothendieck fibration between 1-categories. Suppose that \(J\) is a small category, that \(D: J \to E\) is a diagram, and that

(i) the diagram \(PD: J \to B\) has a limit \(L\) in \(B\) with limit cone \(\lambda: \Delta L \Rightarrow PD\),

(ii) the diagram \(\lambda^*D: J \to E_L\)

constructed by lifting the cone \(\lambda\) to a cartesian natural transformation \(\chi: \lambda^*D \Rightarrow D\) has a limit \(M\) in the fibre \(E_L\) with limiting cone \(\mu: \Delta M \Rightarrow \lambda^*D\), and

(iii) the limit \(\mu: \Delta M \Rightarrow \lambda^*D\) is preserved by the re-indexing functor \(u^*: E_L \to E_B\) associated with any arrow \(u: B \to L\) in \(B\).

Then the composite cone \(\Delta M\)

displays \(M\) as a limit of the diagram \(D\) in \(E\).

Proof. Any arrow \(f: E \to E'\) in the domain of a Grothendieck fibration \(P: E \to B\) factors uniquely up to isomorphism through a “vertical” arrow in the fiber \(E_{PE}\) followed by a “horizontal” cartesian lift of \(Pf\) with codomain \(E'\).

Given a cone \(\alpha: \Delta E \Rightarrow D\) with summit \(E \in E\) over \(D\), by (i) its image \(P\alpha: \Delta PE \Rightarrow PD\) factors uniquely through the limit cone \(\lambda: \Delta L \Rightarrow D\) via a map \(b: PE \to L \in B\). By the universal property of the cartesian lift \(\chi\) of \(\lambda\) constructed in (ii), it follows that \(\alpha\) factors uniquely through \(\chi\) via a natural transformation \(\beta: \Delta E \Rightarrow \lambda^*D\) so that \(P\beta = \Delta b\). This arrow factors uniquely up to isomorphism via “vertical” natural transformation \(\gamma: \Delta E \Rightarrow b^*\lambda^*D\) followed by a “horizontal” cartesian lift of \(b\). By (iii), the limit cone \(\mu: \Delta M \Rightarrow \lambda^*D\) in \(E_L\) pulls back along \(b\) to a limit cone in \(E_{PE}\) through which the pullback of \(\beta\) factors via a map \(k: E \to b^*M\). Thus, \(\beta\) itself factors uniquely through \(\mu\) via the composite of this map \(k: E \to b^*M\) with the cartesian arrow \(b^*M \Rightarrow M\) lifting \(b: PE \to L\). \(\square\)

For example, the codomain-projection functor \(\text{cod}: K^\flat \to K\) is a Grothendieck fibration of underlying 1-categories, with cod-cartesian lifts defined by pullback squares. Since right adjoint right inverses to isofibrations can be constructed as fibered adjunctions by Lemma 3.6.8, and fibered adjunctions are stable under pullback by Lemma 3.6.6, this Grothendieck fibration restricts to define a Grothendieck fibration \(\text{Pari}(K) \to K\), which allows us to appeal to Lemma 6.4.8 in the proof of the following result:
6.4.9. Proposition. For any ∞-cosmos $\mathcal{K}$, the ∞-cosmos of isofibrations admits cosmologically embedded ∞-cosmoi

$$\mathcal{R}_\text{ari}(\mathcal{K}) \hookrightarrow \mathcal{K} \iff \mathcal{L}_\text{ari}(\mathcal{K})$$

whose

- objects are isofibrations admitting a right adjoint right inverse or left adjoint right inverse, respectively, and
- 0-arrows are commutative squares between the right or left adjoints, respectively, whose mates are isomorphisms.

We refer to a commutative square between right adjoints whose mate is an isomorphism as an exact square.

Proof. By Proposition B.3.8 and Exercise B.4.i, the quasi-categorically enriched subcategories $\mathcal{R}_\text{ari}(\mathcal{K})$ and $\mathcal{L}_\text{ari}(\mathcal{K})$ are replete in $\mathcal{K}^e$, so by Proposition 6.4.3 we need only check that $\mathcal{R}_\text{ari}(\mathcal{K}) \hookrightarrow \mathcal{K}^e$ is closed under flexible weighted limits; the argument for $\mathcal{L}_\text{ari}(\mathcal{K}) \hookrightarrow \mathcal{K}^e$ is dual. We argue separately for cotensors and for the conical limits.

If $p: E \twoheadrightarrow B$ is an isofibration admitting a right adjoint right inverse in $\mathcal{K}$ and $U$ is a simplicial set, then the cosmological functor $(-)^U: \mathcal{K} \rightarrow \mathcal{K}$ carries this data to a right adjoint right inverse to $p^U: E^U \twoheadrightarrow B^U$, which proves that the simplicial cotensor in $\mathcal{K}^e$ of an object in $\mathcal{R}_\text{ari}(\mathcal{K})$ lies in $\mathcal{R}_\text{ari}(\mathcal{K})$. To conclude that $\mathcal{R}_\text{ari}(\mathcal{K})$ is closed in $\mathcal{K}^e$ under simplicial cotensors, we must also verify that $p^U$ has the enriched universal property of the simplicial cotensor in $\mathcal{R}_\text{ari}(\mathcal{K})$: that is, we must show that the natural isomorphism $\text{Fun}(q, p^U) \cong \text{Fun}(q, p)$ of functor spaces in $\mathcal{K}^e$ restricts to define a natural isomorphism of functor spaces in $\mathcal{R}_\text{ari}(\mathcal{K})$. Since the inclusion $\mathcal{R}_\text{ari}(\mathcal{K}) \hookrightarrow \mathcal{K}^e$ is full on 0-arrows, this amounts to verifying that certain 0-arrows in $\mathcal{K}^e$ are exact squares.

The weighted limit cone for the cotensor $p^U$ in $\mathcal{K}^e$ is given by the canonical map of simplicial sets $U \rightarrow \text{Fun}(p^U, p)$ defined on each vertex $u: 1 \rightarrow U$ by the commutative square

$$
\begin{array}{ccc}
E^U & \xrightarrow{u^*} & E \\
p^U \downarrow & & \downarrow p \\
B^U & \xrightarrow{u^*} & B
\end{array}
$$

The maps $u^*$ define the components of a simplicial natural transformation from $(-)^U$ to the identity functor and thus the mate of this commutative square is an identity, so the limit cone for the $U$-cotensor lies in $\mathcal{R}_\text{ari}(\mathcal{K})$. Finally, to verify the universal property of the cotensor in $\mathcal{R}_\text{ari}(\mathcal{K})$, we must show that for any commutative square whose domain is an isofibration admitting a right adjoint right inverse

$$
\begin{array}{ccc}
F & \longrightarrow & E^U \\
q \downarrow & & \downarrow p^U \\
A & \longrightarrow & B^U
\end{array}
$$

that composes with each of the squares (6.4.10) to an exact square is itself exact. To see this take the mate to define a 1-arrow in $\text{Fun}(A, E^U) \cong \text{Fun}(A, E)^U$ and note that the hypothesis says that the components of this 1-arrow are invertible for each vertex of $U$. Corollary 1.1.21 then tells us that this 1-arrow is invertible as required.
A similar and slightly easier argument proves that $\mathcal{R}ari(\mathcal{K})$ is closed in $\mathcal{K}^\delta$ under products. It remains only to show that this subcategory is closed under the remaining conical limits. As argued above cod: $\mathcal{R}ari(\mathcal{K}) \to \mathcal{K}$ is a Grothendieck fibration on underlying 1-categories whose fibers, by Exercise 6.4.iii, are the $\infty$-cosmoi $\mathcal{R}ari(\mathcal{K})_B$. By Lemma 6.4.8, the 1-categorical limit cones in $\mathcal{R}ari(\mathcal{K}) \subset \mathcal{K}^\delta$ can be calculated as composites of cartesian lifts of limit cones in the base with limit cones of fiberwise diagrams: in this case, the recipe is to pullback along the limit cone formed by the codomains and then form the limit in the sliced $\infty$-cosmos over the limit object for the base diagram. By Corollary 6.4.7, these fiberwise limits in the sliced $\infty$-cosmos $\mathcal{K}/B$ lie in $\mathcal{R}ari(\mathcal{K})_B \subset \mathcal{R}ari(\mathcal{K})$. Moreover, these 1-categorical limits are preserved by the simplicial cotensor, which by Proposition A.5.6 implies that their universal property enriches to define conical limits. In this way we see that $\mathcal{R}ari(\mathcal{K}) \hookrightarrow \mathcal{K}^\delta$ is closed under flexible weighted limits and thus defines a cosmological embedding, as claimed.

Now that we have established many examples of $\infty$-cosmoi and cosmologically embedded replete subcategories, we can make use of the following result:

6.4.11. Proposition. Suppose $F: \mathcal{K}' \to \mathcal{K}$ is a cosmological functor and $\mathcal{L} \subset \mathcal{K}$ is a replete subcategory that defines a cosmologically embedded $\infty$-cosmos. Then the simplicially enriched category defined by the pullback

$$
\begin{array}{ccc}
\mathcal{L}' & \longrightarrow & \mathcal{L} \\
\downarrow & & \downarrow \\
\mathcal{K}' & \longrightarrow & \mathcal{K}
\end{array}
$$

is replete and defines a cosmologically embedded $\infty$-subcosmos of $\mathcal{K}'$, and the restricted functor $F: \mathcal{L}' \to \mathcal{L}$ is cosmological.

Proof. The objects and $n$-arrows of the pullback $\mathcal{L}'$ are defined to be the objects and $n$-arrows of $\mathcal{K}'$ whose image under $F$ lies in the simplicial subcategory $\mathcal{L}$. In particular, since the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$ is full on positive-dimensional arrows, the inclusion $\mathcal{L}' \hookrightarrow \mathcal{K}'$ is as well, and in particular $\mathcal{L}'$ is quasi-categorically enriched. Since the cosmological functor $F$ preserves equivalences and $\mathcal{L} \hookrightarrow \mathcal{K}$ is replete, the quasi-categorically enriched subcategory $\mathcal{L}'$ is replete in $\mathcal{K}'$, satisfying the three conditions of Definition 6.4.1.

To prove that the replete subcategory $\mathcal{L}' \hookrightarrow \mathcal{K}'$ admits an $\infty$-cosmos structure created by the inclusion, it remains to argue that $\mathcal{L}'$ is closed under flexible weighted limits in $\mathcal{K}'$. Consider a diagram $D: \mathcal{A} \to \mathcal{L}'$ and a flexible weight and form its flexible weighted limit in $\mathcal{L}$ and in $\mathcal{K}$. The functors to $\mathcal{K}$ carry these to a pair of equivalent cones over the same diagram and since the inclusion $\mathcal{L} \hookrightarrow \mathcal{K}$ is replete, there exists a limit cone over $D$ in $\mathcal{L}$ whose image in $\mathcal{K}$ is equal to the image of the limit cone in $\mathcal{K}'$ under the functor $F$. Now the universal property of the pullback allows us to lift this cone to $\mathcal{L}'$, and a similar argument demonstrates that the lifted cone is a flexibly weighted limit cone over the original diagram. Note by construction that the flexible weighted limit in $\mathcal{L}'$ is preserved by the functors to both $\mathcal{K}'$ and to $\mathcal{L}$.

Proposition 6.4.3 applies to conclude that $\mathcal{L}' \hookrightarrow \mathcal{K}'$ is a cosmological embedding. Since the isofibrations in $\mathcal{L}'$ are created in $\mathcal{K}'$ and preserved by $F$, and $\mathcal{L} \hookrightarrow \mathcal{K}$ is a cosmological embedding, it follows that the restricted functor $F: \mathcal{L}' \to \mathcal{L}$ preserves isofibrations. Since $F: \mathcal{L}' \to \mathcal{L}$ preserves flexible weighted limits, we see that this functor is cosmological.

This result allows us to construct further $\infty$-cosmoi of interest.
6.4.12. **Proposition.** For any \( \infty \)-cosmos \( \mathcal{K} \) and simplicial set \( J \), there cosmologically embedded \( \infty \)-cosmoi

\[
\mathcal{K}_{T,J} \longleftarrow \mathcal{K} \longleftrightarrow \mathcal{K}_{\perp,J}
\]

whose

- objects are \( \infty \)-categories in \( \mathcal{K} \) that admit all limits of shape \( J \) or all colimits of shape \( J \), respectively,
- 0-arrows are the functors that preserve them

Moreover for each object of \( \mathcal{K}_{T,J} \) or \( \mathcal{K}_{\perp,J} \) defined as a flexible weighted limit of some diagram in that \( \infty \)-cosmos, its \( J \)-shaped limits or colimits are created by the 0-arrow legs of the limit or colimit cones respectively.

**Proof.** We prove this in the case of \( \infty \)-categories admitting \( J \)-shaped colimits, the other case being dual. For any fixed simplicial set \( J \), there is a cosmological functor \( F_J : \mathcal{K} \to \mathcal{K}^\perp \) defined on objects by mapping an \( \infty \)-category \( A \) to the isofibration \( A^J \to A \) in the notation of 4.2.6 and a functor \( f : A \to B \) to the commutative square

\[
\begin{array}{ccc}
A^J & \xrightarrow{f^J} & B^J \\
\downarrow & & \downarrow \\
A & \xrightarrow{f} & B
\end{array}
\]

By Corollary 4.3.5, \( A \) admits colimits of shape \( J \) if and only if this isofibration admits a left adjoint right inverse, and \( f : A \to B \) preserves these colimits if and only if the square displayed above is exact. In summary, the quasi-categorically enriched subcategory \( \mathcal{K}_{\perp,J} \) is defined by the pullback

\[
\mathcal{K}_{\perp,J} \longleftarrow \text{Lari}(\mathcal{K})
\]

By Proposition 6.4.9, \( \text{Lari}(\mathcal{K}) \hookrightarrow \mathcal{K}^\perp \) is a cosmological embedding, so Proposition 6.4.11 proves that the inclusion \( \mathcal{K}_{\perp,J} \hookrightarrow \mathcal{K} \) creates an \( \infty \)-cosmos structure, as claimed.

In particular, the closure of the subcategory \( \mathcal{K}_{\perp,J} \) under flexible weighted limits in \( \mathcal{K} \) implies that \( J \)-shaped colimits in an \( \infty \)-category defined as a flexible weighted limit are created by the 0-arrow legs of the limit cone, as we explain. Certainly the colimits in an \( \infty \)-category in \( \mathcal{K}_{\perp,J} \), formed as a weighted limit of a diagram of \( \infty \)-categories in \( \mathcal{K}_{\perp,J} \), are preserved by the 0-arrow legs of the weighted limit cone, since the 0-arrows in \( \mathcal{K}_{\perp,J} \) are \( J \)-shaped-colimit-preserving functors. And since the \( J \)-colimit completeness of an \( \infty \)-category that is defined as the flexible weighted limit in \( \mathcal{K} \) can be deduced whenever that diagram lies in the sub \( \infty \)-cosmos \( \mathcal{K}_{\perp,J} \), these \( J \)-colimits are also created. \( \square \)

6.4.13. **Proposition.** For any \( \infty \)-cosmos \( \mathcal{K} \), the \( \infty \)-cosmos of isofibrations admits cosmologically embedded \( \infty \)-cosmoi

\[
\text{Cart}(\mathcal{K}) \hookrightarrow \mathcal{K}^\perp \hookleftarrow \text{coCart}(\mathcal{K})
\]

whose objects are cartesian or cocartesian fibrations, respectively, and whose 0-arrows are cartesian functors. Similarly, for any \( \infty \)-category \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \), the sliced \( \infty \)-cosmos \( \mathcal{K}_{/B} \) admits cosmologically embedded \( \infty \)-cosmoi

\[
\text{Cart}(\mathcal{K})_{/B} \hookrightarrow \mathcal{K}_{/B} \hookleftarrow \text{coCart}(\mathcal{K})_{/B}
\]
whose objects are cartesian or cocartesian fibrations over \( B \), respectively, and whose \( 0 \)-arrows are cartesian functors, with the \( \infty \)-cosmos structures created by the inclusions.

**Proof.** By Theorems 5.2.10 and 5.3.4, the quasi-categorically enriched category \( \text{Cart}(\mathcal{K}) \) is defined by the pullback

\[
\begin{array}{c}
\text{Cart}(\mathcal{K}) \downarrow \quad \downarrow \quad \Downarrow \quad \Downarrow \\
\mathcal{K}^\downarrow \quad \mathcal{K}^\downarrow \\
\mathcal{U} \quad \mathcal{U} \\
\end{array}
\]

along the simplicial functor \( K \) that sends an isofibration \( p : E \to B \) to the isofibration \( \mathcal{U} \) defined as a Leibniz cotensor by Remark 5.2.12. To see this, recall from Proposition 6.4.9 that the \( 0 \)-arrows in the functor spaces of \( \mathcal{U} \) are commutative squares between isofibrations admitting a right adjoint right inverse so that the mate of the identity 2-cell induces an isomorphism in the corresponding square involving the left adjoints. By Theorem 5.3.4, this condition pulls back along the functor \( K \) to tell us that \( 0 \)-arrows in \( \text{Cart}(\mathcal{K}) \) are commutative squares between cocartesian fibrations that define cartesian functors in the sense of Definition 5.3.2.

The simplicial functor \( K \) is constructed out of weighted limits and thus preserves all weighted limits. In addition, it preserves the isofibrations of Proposition 6.1.1; if \( r : F \to P \) is the isofibration from the initial vertex to the pullback of the cospan displayed in 6.1.1(iii), then the corresponding map under the image of the functor \( K \) is the Leibniz cotensor \( \mathcal{U} \). Thus, \( K \) is a cosmological functor. By Proposition 6.4.11, the inclusion \( \text{Cart}(\mathcal{K}) \hookrightarrow \mathcal{K}^\downarrow \) creates an \( \infty \)-cosmos structure.

We have a similar pullback defining the quasi-categorically enriched category of cartesian fibrations with a fixed base

\[
\begin{array}{c}
\text{Cart}(\mathcal{K}) \downarrow \quad \downarrow \\
\mathcal{K}^\downarrow \quad \mathcal{K}^\downarrow \\
\mathcal{U} \quad \mathcal{U} \\
\end{array}
\]

but we cannot appeal to Proposition 6.4.11 because the inclusion \( \mathcal{K}^\downarrow \hookrightarrow \mathcal{K}^\downarrow \) is neither cosmological nor replete. Instead we must appeal to Proposition 6.4.3. By Corollary 5.3.1 and Theorem 5.3.4, \( \text{Cart}(\mathcal{K}) \hookrightarrow \mathcal{K}^\downarrow \) is a replete subcategory. The connected conical limits in \( \text{Cart}(\mathcal{K}) \) and \( \mathcal{K}^\downarrow \) are created by the inclusions into \( \text{Cart}(\mathcal{K}) \) and \( \mathcal{K}^\downarrow \), so these are created by the inclusion \( \text{Cart}(\mathcal{K}) \hookrightarrow \mathcal{K}^\downarrow \). It remains only to argue directly that product and simplicial cotensors are created by this inclusion.

By Proposition 1.2.22, the product of isofibrations \( p_i : E_i \to B \) is formed by the pullback

\[
\begin{array}{c}
x_i^B E_i \downarrow \quad \downarrow \\
x_i^B p_i \quad \Delta \\
B \quad \Pi_i B \\
\end{array}
\]

If each \( p_i \) is a cartesian fibration, then since \( \text{Cart}(\mathcal{K}) \) is an \( \infty \)-cosmos, so is \( \Pi_i p_i \), and the legs of the limit cone are cartesian functors. By Proposition 5.2.4 it follows that their product in \( \mathcal{K}^\downarrow \) is a cartesian
fibration and the legs of the limit cone, defined by composing the pullback square with the product projections, are cartesian functors. Since cartesian transformations are created by pullbacks, it follows easily that a square with codomain $\times_i^B p_i$ is a cartesian functor if and only if each of the composite squares with codomain $p_i$ are cartesian functors. This proves that products are created by the inclusion $\text{Cart}(\mathcal{K})/B \hookrightarrow \mathcal{K}/B$.

Similarly, by Proposition 1.2.22, the cotensor of an isofibration $p : E \rightarrow B$ with a simplicial set $U$ is formed by the pullback

$$
\begin{array}{c}
U \downarrow \Phi_B \quad \quad \quad \quad E^U \\
\downarrow \quad \quad \quad \quad \downarrow p^U \\
B \quad \quad \quad \quad B^U
\end{array}
$$

and hence is a cartesian fibration if $p$ is. A similar argument shows that this object has the universal property required of the simplicial cotensor in $\text{Cart}(\mathcal{K})/B$, completing the proof. □

The ∞-cosmoi of cartesian fibrations provide a fertile setting to explore the parametrized ∞-category theory developed by Jay Shah [111].

6.4.14. PROPOSITION. For any ∞-cosmos $\mathcal{K}$, there exist cosmologically embedded ∞-cosmoi

$$
\begin{array}{ccc}
\text{DiscCart}(\mathcal{K}) & \rightarrow & \mathcal{K}^\ast & \leftarrow & \text{DisccoCart}(\mathcal{K}) \\
\downarrow & & \downarrow & & \downarrow \\
\text{Cart}(\mathcal{K}) & \leftarrow & \text{coCart}(\mathcal{K})
\end{array}
$$

whose objects are discrete cartesian or discrete cocartesian fibrations. Similarly, for any ∞-category $B$ in an ∞-cosmos $\mathcal{K}$, there exist cosmologically embedded ∞-cosmoi

$$
\begin{array}{ccc}
\text{DiscCart}(\mathcal{K})_B & \rightarrow & \mathcal{K}_B^\ast & \leftarrow & \text{DisccoCart}(\mathcal{K})_B \\
\downarrow & & \downarrow & & \downarrow \\
\text{Cart}(\mathcal{K})_B & \leftarrow & \text{coCart}(\mathcal{K})_B
\end{array}
$$

whose objects are discrete cartesian or discrete cocartesian fibrations over $B$, respectively.

PROOF. By Exercise 6.4.v, the ∞-cosmoi of discrete fibrations with a fixed base arise as ∞-cosmoi of discrete objects:

$$
\text{DiscCart}(\mathcal{K})_B \cong (\text{Cart}(\mathcal{K})_B)^\ast \quad \text{and} \quad \text{DisccoCart}(\mathcal{K})_B \cong (\text{coCart}(\mathcal{K})_B)^\ast
$$

and hence their existence is guaranteed by Proposition 6.1.6.

The ∞-cosmoi of discrete fibrations with varying bases arise as pullbacks

$$
\begin{array}{ccc}
\text{DiscCart}(\mathcal{K}) & \rightarrow & \mathcal{K}^\ast & \leftarrow & \text{DisccoCart}(\mathcal{K}) \\
\downarrow & & \downarrow & & \downarrow \\
\text{Cart}(\mathcal{K}) & \leftarrow & \text{coCart}(\mathcal{K})
\end{array}
$$

along restrictions of the cosmological functor $K$ defined in the proof of Proposition 6.4.13, and hence exist by Proposition 6.4.11. □

6.4.15. PROPOSITION. For any ∞-cosmos $\mathcal{K}$, the replete subcategory $\text{Stab}(\mathcal{K})$ of stable ∞-categories and exact functors in $\mathcal{K}$ is an ∞-cosmos and the inclusion $\text{Stab}(\mathcal{K}) \hookrightarrow \mathcal{K}$ is a cosmological embedding.
Recall from Exercise 4.4.iv that in this context that a functor between stable ∞-categories is called **exact** just when it preserves zero elements and the so-called exact squares, that define both pushouts and pullbacks.

**Proof.** Simplifying the notation of Proposition 6.4.12, write $\mathcal{K}_\partial$ and $\mathcal{K}_\eta$ for the ∞-cosmoi of ∞-categories in $\mathcal{K}$ that admit pullbacks and pushouts respectively. We argue that the ∞-cosmoi $(\mathcal{K}_\partial)_\eta \cong (\mathcal{K}_\eta)_\partial$ are isomorphic as replete subcategories of $\mathcal{K}$. An object of $(\mathcal{K}_\partial)_\eta$ is an ∞-category $A$ in $\mathcal{K}_\partial$ that admits an adjunction

$$
\begin{array}{c}
A^\square \xleftarrow{\text{lan}} A^\circ \\
\downarrow \quad \downarrow
\end{array}
$$

in the ∞-cosmos $\mathcal{K}_\partial$, meaning that the functor $\text{lan}: A^\eta \to A^\square$ preserves the pullbacks that both of these ∞-categories admit. Since $A$ itself admits pullbacks, the pullbacks in $A^\circ$ and $A^\square$ may be defined pointwise, via the adjunctions

$$
\begin{array}{c}
(A^\eta)^\square \downarrow \quad (A^\eta)^\circ \\
\leftarrow \quad \leftarrow \quad \leftarrow \quad \leftarrow
\end{array}
$$

and so are automatically preserved by the restriction functor. Thus the condition that this adjunction lies in $\mathcal{K}_\partial$ amounts to the condition that the canonical natural transformation

$$
\begin{array}{c}
(A^\eta)^\square \xrightarrow{\text{lan}^\square} (A^{\square})^\square \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow
\end{array}
$$

is an isomorphism.

Dually, an object of $(\mathcal{K}_\eta)_\partial$ is an ∞-category $A$ that admits pushouts and also admits an adjunction

$$
\begin{array}{c}
A^\square \xleftarrow{\text{res}} A^\circ \\
\downarrow \quad \downarrow
\end{array}
$$

in the ∞-cosmos $\mathcal{K}_\eta$, meaning that the pullback functor $\text{ran}: A^\circ \to A^\square$ preserves the pointwise-defined pushouts: i.e., that the canonical natural transformation

$$
\begin{array}{c}
(A^\circ)^\square \xrightarrow{\text{ran}^\square} (A^{\square})^\circ \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow
\end{array}
$$

is an isomorphism. Thus, we see that the objects of $(\mathcal{K}_\partial)_\eta$ and $(\mathcal{K}_\eta)_\partial$ coincide. Similarly, the 0-arrows in each of $(\mathcal{K}_\partial)_\eta$ and $(\mathcal{K}_\eta)_\partial$ are functors that preserve both pullbacks and pushouts. This proves that $(\mathcal{K}_\partial)_\eta$ and $(\mathcal{K}_\eta)_\partial$ define isomorphic subcategories of $\mathcal{K}$, as claimed. A similar simpler observation justifies the assertion $(\mathcal{K}_\top)_\bot \cong (\mathcal{K}_\bot)_\top$ made in the proof of Proposition 6.4.6.

By Theorem 4.4.12(iii), an ∞-category is stable just when it is pointed, admits pullbacks and pushouts, and the pullback functor preserves pushouts, and the pushout functor preserves pullbacks.
By the proof of Theorem 4.4.12(iii)\(\Rightarrow\)(ii) these conditions imply that pullback and pushout squares coincide. In this way we see that \(\text{Stab}(\mathcal{K})\) is the intersection

\[
\text{Stab}(\mathcal{K}) \quad \xleftarrow{\mathcal{A}} \quad (\mathcal{K}_{\mathcal{A}})_{\mathcal{S}} \cong (\mathcal{K}_{\mathcal{A}})_{\mathcal{S}} \\
\downarrow \quad \downarrow
\]

\[
(\mathcal{K}_{\mathcal{T}})_{\mathcal{T}} \cong (\mathcal{K}_{\mathcal{T}})_{\mathcal{T}} \quad \xleftarrow{} \quad \mathcal{K}
\]

of cosmologically embedded \(\infty\)-cosmoi and thus is itself a cosmologically embedded \(\infty\)-cosmos by Proposition 6.4.11.

The results in this section can be used to prove technical results in the \(\infty\)-categorical literature; see Example 6.4.vi. We close with a few illustrations of results along these lines.

6.4.16. Lemma. Consider a pullback diagram of \(\infty\)-categories, whose vertical functors are isofibrations.

\[
\begin{array}{ccc}
F & \xrightarrow{h} & E \\
\downarrow{q} & & \downarrow{p} \\
A & \xrightarrow{k} & B
\end{array}
\]

Then \(q\) creates and \(h\) preserves any class of limits or colimits that \(k\) preserves and \(p\) creates.

**Proof.** The hypotheses ensure that the underlying cospan of the pullback lies in the \(\infty\)-cosmos of Proposition 6.4.12. Since this is a cosmologically embedded \(\infty\)-cosmos, it follows that the pullback of \(\infty\)-categories lies in there as well, which tells us that \(F\) admits and \(q\) and \(h\) preserve any limits or colimits that are present in \(E, A,\) and \(B\) and preserved by \(p\) and \(k\).

It remains only to argue that such (co)limits are created by \(q: F \rightarrow A\). Suppose \(d: D \rightarrow F^J\) is a family of diagrams and \(\eta: d \Rightarrow \Delta c\) is a cone under this diagram so that \(q\eta\) is a colimit cone for \(qd\) in \(A\). Then \(kq\eta = ph\eta\) is a colimit cone for \(kqd = phd\) in \(B\). Since \(p: E \rightarrow B\) is assumed to create colimits, this tells us that \(h\eta\) is a colimit cone for \(hd\) in \(E\). Now the second statement of Proposition 6.4.12, which tells us that (co)limits in \(F\) are jointly created by the functors \(q\) and \(h\), allows us to conclude that \(\eta\) is a colimit cone in \(F\) as claimed.

Our final application reproves a result [77, 1.4.2.24] relevant to the theory of stable \(\infty\)-categories.

6.4.17. Lemma. Suppose \(A\) is a pointed \(\infty\)-category admitting pullbacks. Then the homotopy limit of the tower of loops functors

\[
\cdots \rightarrow A \rightarrow A \xrightarrow{\Omega} A \xrightarrow{\Omega} A
\]

defines a stable \(\infty\)-category \(\text{Sp}A\).

**Proof.** Since the loops functors are not isofibrations, the homotopy limit of the tower of loops functors is calculated by first replacing each map by an isofibration in the ambient \(\infty\)-cosmos \(\mathcal{K}\) and then forming the inverse limit. Alternatively, by Lemmas 6.3.11 and 6.3.12 we can just form the iso-tower:

\[
\begin{array}{ccc}
\text{Sp}A & \xrightarrow{\phi} & \prod_{n \in \omega} A^\Pi \\
\downarrow{\rho} & & \downarrow{\prod(q_1, q_0)} \\
\prod_{n \in \omega} A & \xrightarrow{\Omega{id}} & \prod_{n \in \omega} A \times A
\end{array}
\] (6.4.18)
which defines $\text{Sp}A$ to be the universal $\infty$-category equipped with a cone

$$
\begin{array}{c}
\text{Sp}A \\
\downarrow\rho_0 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_1} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_2 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_3} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_4 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_5} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_6 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_7} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_8 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_9} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_10 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_11} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_12 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_13} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_14 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_15} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_16 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_17} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_18 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_19} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_20 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_21} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_22 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_23} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_24 \\
\prod_{n \in \omega} A
\end{array}
\xrightarrow{\rho_25} 
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_26 \\
\prod_{n \in \omega} A
\end{array}
$$

in which each triangle is inhabited by a homotopy coherent isomorphism.

Since $A$ is pointed and admits pullbacks, it lies in the $\infty$-cosmos $(\mathcal{K}_*)_\omega \hookrightarrow \mathcal{K}$. Note that pullback functors automatically preserve zero elements, so $(\mathcal{K}_*)_\omega \cong \mathcal{K}_* \cap \mathcal{K}_\omega$. For the same reason, the loops functor preserves zero elements and pullbacks, so the loops functor $\Omega: A \to A$ also lies in $(\mathcal{K}_*)_\omega$. Since this $\infty$-cosmos is cosmologically embedded in $\mathcal{K}$, it follows that the iso-tower $\text{Sp}A$ is again a pointed $\infty$-category that admits pullbacks, and each of the functors $\rho_n: \text{Sp}A \to A$ preserve them.

Indeed, by Propositions 6.4.6 and 6.4.12 the zero element and products are created by the legs $\rho_n$ of the limit cone, which tells us that its loops functor can be chosen to commute with these projections:

$$
\begin{array}{c}
\text{Sp}A \\
\downarrow\rho
\end{array}
\xrightarrow{\rho}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\prod\Omega
\end{array}
$$

By the universal property of $\text{Sp}A$ as a flexible weighted limit we can induce another endofunctor $\Sigma^*: \text{Sp}A \to \text{Sp}A$ from the data of the weighted cone

$$
\begin{array}{c}
\text{Sp}A \\
\downarrow\rho_0
\end{array}
\xrightarrow{\rho_1}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_2
\end{array}
\xrightarrow{\rho_3}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_4
\end{array}
\xrightarrow{\rho_5}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_6
\end{array}
\xrightarrow{\rho_7}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_8
\end{array}
\xrightarrow{\rho_9}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{10}
\end{array}
\xrightarrow{\rho_{11}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{12}
\end{array}
\xrightarrow{\rho_{13}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{14}
\end{array}
\xrightarrow{\rho_{15}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{16}
\end{array}
\xrightarrow{\rho_{17}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{18}
\end{array}
\xrightarrow{\rho_{19}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{20}
\end{array}
\xrightarrow{\rho_{21}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{22}
\end{array}
\xrightarrow{\rho_{23}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{24}
\end{array}
\xrightarrow{\rho_{25}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{26}
\end{array}
\xrightarrow{\rho_{27}}
\begin{array}{c}
\prod_{n \in \omega} A \\
\downarrow\rho_{28}
\end{array}
$$

obtained by restricting along the inclusion $\Sigma: n \mapsto n + 1: \omega^\text{op} \to \omega^\text{op}$ to shift the data in the weighted limit cone. To analyze this functor more formally, consider the factorization of the natural isomorphism $\sigma: W^\leftarrow \cong W^\leftarrow \Sigma$ through the left Kan extension:

$$
\begin{array}{c}
\omega^\text{op} \\
\downarrow W^\leftarrow
\end{array}
\xrightarrow{\sigma}
\begin{array}{c}
\text{sSet}
\end{array}
\xrightarrow{\Sigma}
\begin{array}{c}
\omega^\text{op} \\
\downarrow W^\leftarrow
\end{array}
\xrightarrow{\eta}
\begin{array}{c}
\text{sSet}
\end{array}
$$

In this way, the map $\Sigma^*$ fits into a commutative diagram of induced maps on weighted limits

$$
\begin{array}{c}
\text{lim}_{W^\leftarrow} F \\
\downarrow a^*
\end{array}
\xrightarrow{\Sigma^*} 
\begin{array}{c}
\text{lim}_{W^\leftarrow} F \Sigma \\
\downarrow a^* \Sigma^*
\end{array}
\xrightarrow{\sigma^*} 
\begin{array}{c}
\text{lim}_{W^\leftarrow} F \Sigma \\
\downarrow a^* \Sigma^*
\end{array}
\xrightarrow{\eta^*}
\begin{array}{c}
\text{lim}_{W^\leftarrow} F \Sigma \\
\downarrow a^* \Sigma^*
\end{array}
$$

Note the bottom horizontal composite exhibits the isomorphism of Lemma A.6.20 by a general result of enriched category theory [67, 4.63] that says that the weighted limit of a restricted diagram agrees with the limit weighted by the left Kan extension of the weight. From this result and the isomorphisms $\sigma: W^\leftarrow \cong W^\leftarrow \Sigma$ and $F \cong F \Sigma$ we see that all of the objects in this diagram are isomorphic to $\text{Sp}A$. 

232
Since \( \Sigma \) is fully faithful, \( \eta \) is an isomorphism, and hence so is \( \alpha \Sigma \), so the map \( \Sigma^* : \text{Sp} A \to \text{Sp} A \) of interest is isomorphic to the map induced on weighted limits from the inclusion \( \alpha : \text{lan}_\Sigma W^\leftarrow W^\leftarrow \). This map is a projective cell complex between flexible weights, defined by attaching a single generalized projective cell \( \mathbb{I} \times \omega(\mathbb{I},0) \hookrightarrow \mathbb{I} \times \omega(\mathbb{I},0) \) at 0. Put another way, it is an isomorphism on all but one component; via the isomorphism \( W^\leftarrow \cong \text{lan}_\Sigma W^\leftarrow \Sigma \), its zeroth component is \( \alpha_0 : W^\leftarrow_0 \to W^\leftarrow_0^\leftarrow \). Thus, we see that \( \alpha \) defines a pointwise Joyal weak equivalence between projective cell complexes. It follows from the pullback diagram

\[
\begin{array}{ccc}
\lim_{\Sigma W^\leftarrow} F & \longrightarrow & \lim_{\mathbb{I} \times \omega(\mathbb{I},0)} F \\
\alpha^* \downarrow & & \downarrow \\
\lim_{\text{lan}_\Sigma W^\leftarrow} F & \longrightarrow & \lim_{\mathbb{I} \times \omega(\mathbb{I},0)} F
\end{array}
\]

that the induced map on weighted limits \( \Sigma^* : \text{Sp} A \to \text{Sp} A \) is an equivalence.

By construction the composite \( \Omega \Sigma^* : \text{Sp} A \to \text{Sp} A \) is naturally isomorphic to the identity functor, where this isomorphism can be induced by the weak universal property of the pullback (6.4.18) from the isomorphisms \( \Omega \rho_{n+1} \cong \rho_n \) of the weighted limit cone. Thus, by 2-of-3 and stability of equivalences under natural isomorphism, \( \Omega \) is an equivalence.

We have shown that \( \text{Sp} A \) is a pointed \( \infty \)-category with pullbacks for which the loops functor is an equivalence. By Theorem 4.4.12(v), \( \text{Sp} A \) is a stable \( \infty \)-category as claimed. \( \square \)

**Exercises.**

6.4.i. **Exercise.** Let \( \mathcal{L} \hookrightarrow \mathcal{K} \) be a replete subcategory of an \( \infty \)-cosmos. Show that for all \( A, B \in \mathcal{L} \), the map

\[
\text{Fun}_\mathcal{L}(A, B) \hookrightarrow \text{Fun}_\mathcal{K}(A, B)
\]

is both a monomorphism and an isofibration between quasi-categories. This latter property may be summarized by saying that the simplicial functor \( \mathcal{L} \to \mathcal{K} \) is a local isofibration.\(^3\)

6.4.ii. **Exercise.** For any \( \infty \)-cosmos \( \mathcal{K} \), compare the cosmologically embedded \( \infty \)-cosmoi \( \mathcal{K}_\perp \cap \mathcal{K}_\top \) and \( \mathcal{K}_* := (\mathcal{K}_\top)_\perp \cong (\mathcal{K}_\perp)_\top \) appearing in the discussion surrounding Proposition 6.4.6.

6.4.iii. **Exercise.** Consider a functor between isofibrations

\[
\begin{array}{ccc}
E & \xrightarrow{s} & F \\
p \downarrow & & \downarrow q \\
\mathcal{B} & \xleftarrow{r} & \mathcal{F}
\end{array}
\]

in which \( p \) admits a right adjoint right inverse \( r \) and \( q \) admits a right adjoint right inverse \( s \). Use naturality of whiskering to show that if \( qr \cong s \), then the mate of the identity \( qg = p \) is an isomorphism. This proves that the 0-arrows in the \( \infty \)-cosmos \( \mathcal{R}_\text{ari}(\mathcal{K})/\mathcal{B} \) are exact transformations between right adjoint right inverse adjunctions.

6.4.iv. **Exercise.** Prove that \( \mathcal{L}_\text{ari}(\mathcal{K}) \cong \mathcal{R}_\text{ari}(\mathcal{K}_0)^{\mathcal{B}} \).

\(^3\)The inclusions of replete subcategories are also global isofibrations in a sense appropriate for \((\infty,2)\)-category theory: namely the full data of an equivalence in \( \mathcal{K} \) involving one object in the subcategory \( \mathcal{L} \) can be lifted to \( \mathcal{L} \).
6.4.v. **EXERCISE.** Show that if $\mathcal{L} \hookrightarrow \mathcal{K}$ is a cosmologically embedded $\infty$-cosmos, then an object $A \in \mathcal{L}$ is discrete if and only if $A$ is discrete as an object of $\mathcal{K}$.

6.4.vi. **EXERCISE ([45, 4.1.5]).** Given a diagram

\[
\begin{array}{ccc}
E' & \longrightarrow & E \\
\downarrow & & \downarrow \\
B' & \longrightarrow & B \\
\end{array}
\begin{array}{ccc}
& & \leftarrow \\
& & \downarrow \\
& & B'' \\
\end{array}
\begin{array}{ccc}
& & \leftarrow \\
& & \downarrow \\
& & E'' \\
\end{array}
\]

where the vertical maps are cocartesian fibrations and the squares define cartesian functors, verify that the induced functor

\[E' \times_E E'' \to B' \times_B B''\]

is a cocartesian fibration and the projections define cartesian functors. Show also that if the vertical maps are discrete cocartesian fibrations so is this induced functor.
Part II

The Calculus of Modules
In Chapter 1 we established a convention to refer to an object \(A\) in an \(\infty\)-cosmos \(\mathcal{K}\) as an \("\infty\)-category." The \(\infty\)-cosmos provides access to its elements \(z: 1 \to A\) and to its internal mapping spaces \(\text{Hom}_A(x, y)\), defined as bifibers
\[
\begin{array}{ccc}
\text{Hom}_A(x, y) & \longrightarrow & A^2 \\
\downarrow & & \downarrow (\eta_1, \eta_0) \\
1 & \longrightarrow & A \times A
\end{array}
\]
over a pair of elements. Proposition 3.4.10 proves that internal mapping spaces are discrete \(\infty\)-categories. If \(\mathcal{K}\) is an \(\infty\)-cosmos of \((\infty, 1)\)-categories, then the discrete \(\infty\)-categories are the "\(\infty\)-groupoids" in the \(\infty\)-cosmos, and these structures justify part of the intuition that \((\infty, 1)\)-categories are categories weakly enriched over \(\infty\)-groupoids.

Thus suggests that the arrow \(\infty\)-category is of particular importance. Propositions 3.2.5 and 3.2.6 describe its weak 2-categorical universal property: natural transformations
\[
\begin{array}{ccc}
X & \overset{a}{\longrightarrow} & A \\
\downarrow \sigma g & \swarrow b \\
A
\end{array}
\]

correspond to natural transformations \(\sigma g: X \to A^2\) with \(p_0 \sigma g = a\) and \(p_1 \sigma g = b\) up to fibered isomorphism over \(A \times A\). By Proposition 3.2.10 this weak universal property characterizes the arrow \(\infty\)-category up to fibered equivalence over \(A \times A\). However, it does not capture the additional fact that natural transformations from \(X\) to \(A\) can be composed vertically
\[
\begin{array}{ccc}
X & \overset{a}{\longrightarrow} & A \\
\downarrow \psi g & \swarrow \psi h \\
X & \overset{x}{\longrightarrow} & A
\end{array}
\]

defining commuting contravariant and covariant actions on the domains and codomains of the 2-cell \(g: a \Rightarrow b\).

In Chapter 5, we discovered one way to express the actions, proving in Propositions 5.2.16 and Proposition 5.4.4 that the domain-projection functor \(p_0: A^2 \to A\) and the codomain-projection functor \(p_1: A^2 \to A\) respectively define a cartesian fibration and a cocartesian fibration. Particular \(p_0\)-cartesian lifts and \(p_1\)-cocartesian lifts can be used to define pre- and post-composition functors:

\[
\begin{array}{ccc}
\text{Hom}_A(a, b) & \overset{f^*}{\longrightarrow} & \text{Hom}_A(A, b) \\
\downarrow & \swarrow p_0 \sigma g \\
\text{Hom}_A(x, b) & \overset{a}{\longrightarrow} & A
\end{array}
\]

\[
\begin{array}{ccc}
\text{Hom}_A(a, b) & \overset{h^*}{\longrightarrow} & \text{Hom}_A(a, A) \\
\downarrow & \swarrow p_1 \sigma g \\
\text{Hom}_A(a, y) & \overset{b}{\longrightarrow} & A
\end{array}
\]

with universal properties that imply that \(f^* g^* \simeq (gf)^*\) and \(h^* g_* \simeq (hg)_*\).
To see that the post- and pre-composition actions commute with each other, defining an essentially commutative square

\[
\begin{array}{ccc}
\Hom_A(a, b) & \cong & \Hom_A(a, y) \\
\downarrow f^* & & \downarrow h^* \\
\Hom_A(x, b) & & \Hom_A(x, y) \\
\uparrow h_* & & \uparrow f_*
\end{array}
\]

of functors over \(X\), necessitates considering the codomain and domain-projection functors as a span \(A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A\), rather than individually. This is the aim of Chapter 7, which introduces two-sided fibrations, given by a span whose left leg is a cocartesian fibration and right leg is a cartesian fibration, with commuting “fiberwise” actions.

The span \(A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A\) is not merely a two-sided fibration, but a two-sided fibration that is discrete as an object in the sliced \(\infty\)-cosmos over \(A \times A\). In particular, this implies that the fibers over a pair of elements are discrete \(\infty\)-categories. In terminology introduced at the end of Chapter 7, this discreteness means that \(E\) defines a module from \(A\) to \(B\).

In Chapter 8, we develop the calculus of modules, which closely resembles the calculus of (bi)modules between unital rings. In Chapter 9, we deploy this calculus to further develop the formal category theory of \(\infty\)-categories. Notably, we make use of modules to define and develop pointwise right and left Kan extensions, which are notably missing from Part I. We note also that many of the results in previous chapters encode \(\infty\)-categorical notions as an equivalence of modules. Accordingly, modules form the cornerstone of our proof of the model independence of \((\infty, 1)\)-category theory in Part III.
CHAPTER 7

Two-Sided Fibrations and Modules

In Chapter 5 we studied those families of isofibrations for which the arrows in the base act covariantly or contravariantly on the fibers. A prototypical example of a so-called cocartesian fibration is the codomain-projection functor \( p_1 : A^2 \to A \) associated to the arrow \( \infty \)-category, where the fiberwise action is by postcomposition. Dually, the domain-projection functor \( p_0 : A^2 \to A \) is a cartesian fibration, with fiberwise action by precomposition.

In this section, we refine and sharpen our understanding of these fibration structures by considering the codomain- and domain-projection functors as a span \( A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A \) rather than separately. A few observations come quickly to mind. Firstly, \( p_1 \)-cocartesian lifts can be chosen to define natural transformations with codomain \( A^2 \) whose domain-components are identities; that is, \( p_1 \)-cocartesian lifts can be chosen to lie “over \( p_0 : A^2 \to A \).” Dually, \( p_0 \)-cartesian lifts can be chosen to lie over \( p_1 \)-cocartesian lifts.

Secondly, the pre-composition action on fibers \( f^* : \text{Hom}_A(a, A) \to \text{Hom}_A(x, A) \) induced by a natural transformation \( f : x \Rightarrow a \) with codomain \( A \), commutes with the post-composition action \( h_* : \text{Hom}_A(A, b) \to \text{Hom}_A(A, y) \) induced by \( h : b \Rightarrow y \) in a suitable sense. These first two properties are summarized by saying that the span associated to the arrow \( \infty \)-category defines a two-sided fibration from \( A \) to \( A \).

Finally, the bifibers of the isofibration \( (p_1, p_0) : A^2 \to A \times A \) define discrete \( \infty \)-categories, namely the internal mapping spaces of \( A \). Indeed, \( A^2 \) is itself discrete when considered as an object in the sliced \( \infty \)-cosmos over \( A \times A \). This additional property implies that \( A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A \) defines a discrete two-sided fibration from \( A \) to \( A \), which we abbreviate by saying that \( A^2 \) defines a module from \( A \) to \( A \).

Recall from Proposition 6.4.13 that for any \( \infty \)-category \( B \) in an \( \infty \)-cosmos \( K \), the quasi-categorically enriched categories \( \text{coCart}(K)_B \) and \( \text{Cart}(K)_B \) define \( \infty \)-cosmoi, inheriting their limits, isofibrations, and equivalences from their cosmological embedding into \( K_B \). In this chapter, we introduce another cosmologically embedded \( \infty \)-cosmos \( A(\text{Fib}(K))_B \subset K_{/A \times B} \) whose objects are two-sided fibrations from \( A \) to \( B \). Several equivalent definitions of this notion are given in §7.1. Iterating Proposition 6.4.13 reveals that \( A(\text{Fib}(K))_B \) is again an \( \infty \)-cosmos, which we study in §7.2.

A two-sided fibration from \( B \) to \( 1 \) is simply a cocartesian fibration over \( B \), while a two-sided fibration from \( 1 \) to \( B \) is a cartesian fibration over \( B \), so results about two-sided fibrations simultaneously generalize these one-sided notions. Certain closure properties of two-sided fibrations developed in §7.2, such as closure under pullback, are familiar from Chapter 5, while others, such as closure under span composition, are specific to the two-sided context.

In §7.3, we introduce two-sided representables and prove a two-sided version of the Yoneda lemma, generalizing Theorem 5.7.6 and Corollary 5.7.23 for representable (co)cartesian fibrations. This is the formulation of the Yoneda lemma that will prove most useful going forward.

239
The main reason for our interest in two-sided fibrations is the fact that the discrete objects in \( \mathcal{A} \mathbf{Fib}_B \) are precisely the modules\(^1\) from \( A \) to \( B \), which we define and study in §7.4. The calculus of modules, developed in Chapter 8, is the main site of the formal category theory of \( \infty \)-categories, which is the subject of Chapter 9.

### 7.1. Two-Sided Fibrations

By factoring, any span in \( \mathcal{K} \) from \( A \) to \( B \) may be replaced up to equivalence by a two-sided isofibration, a span \( A \xleftarrow{q} E \xrightarrow{p} B \) for which the functor \( (q, p) : E \to A \times B \) is an isofibration. Two-sided isofibrations from \( A \) to \( B \) are the objects of the \( \infty \)-cosmos \( \mathcal{K}_{/A \times B} \). In this section, we describe what it means for a two-sided isofibration to be cocartesian on the left or cartesian on the right, and then introduce two-sided fibrations, which integrate these notions.

To motivate these concepts, consider the span \( A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A \) associated to the arrow \( \infty \)-category of \( A \) in an \( \infty \)-cosmos \( \mathcal{K} \). In Proposition 5.6.14, we observed that

\[
A^2 \xrightarrow{(p_1, p_0)} A \times A
\]

defines a cartesian fibration in the sliced \( \infty \)-cosmos \( \mathcal{K}_{/A} \)—in fact a discrete cartesian fibration, though we postpone consideration of discreteness until we introduce modules in §7.4. To prove this we invoke Theorem 5.2.10(ii) which characterizes cartesian fibrations via a fibered adjunction over the codomain. In this instance, the fibered adjunction lies in the \( \infty \)-cosmos \( (\mathcal{K}_{/A})_{/A} \xrightarrow{} \mathcal{K}_{/A \times A} \) and is equivalent to the canonical adjunction

\[
\begin{array}{ccc}
2 & \xleftarrow{2 \times 1} & 2 \times 2 \\
\uparrow \delta^0 \downarrow \kappa & & \uparrow \ell \downarrow \sigma^0 \\
(1, 0) & \xleftarrow{\delta^1} & (2, 0)
\end{array}
\]

\[
\begin{array}{ccc}
2 \times 2 & \xrightarrow{2 \times 1} & 2 \times 1 \\
\uparrow \delta^0 \downarrow \kappa & & \uparrow \ell \downarrow \sigma^0 \\
(1, 0) & \xleftarrow{\delta^1} & (2, 0)
\end{array}
\]

arising from an adjunction between the indexing categories. In terminology we presently introduce this is what it means to say that the two-sided isofibration \( A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A \) is cartesian on the right.

When we postcompose with the projection \( \pi : A \times A \to A \) onto the right factor, we are left with an adjunction

\[
\begin{array}{ccc}
A^2 & \xrightarrow{p_1} & A^3 \\
\downarrow \sigma^0 \uparrow \pi & & \downarrow r \uparrow \tau_{p_0} \uparrow \tau_{p_0} \\
A \times A & \xrightarrow{(p_1, p_0)} & A^3
\end{array}
\]

\[
\begin{array}{ccc}
A^2 & \xrightarrow{p_1} & A^3 \\
\downarrow \sigma^0 \uparrow \pi & & \downarrow r \uparrow \tau_{p_0} \uparrow \tau_{p_0} \\
A \times A & \xrightarrow{(p_1, p_0)} & A^3
\end{array}
\]

\[1\)In the 1- and \( \infty \)-categorical literature, the names “distributor” [8], “profunctor” [128], and “correspondence” [3, 74] are all used as synonyms for “module.”
that witnesses the fact established in Proposition 5.2.16 that $p_0: A^2 \to A$ is a cartesian fibration. So part of what it means for a two-sided isofibration to be cartesian on the right is that its right leg is a cartesian fibration. To say that this adjunction lies over $A \times A$ not merely over $A$ amounts to the assertion that $p_0$-cartesian lifts can be chosen to lie in fibers of $p_1: A^2 \to A$, whiskering along the left leg to identity arrows. It follows that every $p_0$-cartesian transformation whiskers with $p_1$ to an isomorphism.

These two properties can be expressed in another way: by demanding that the functor

$$
\begin{array}{ccc}
A^2 & \xrightarrow{(p_1,p_0)} & A \times A \\
p_0 & \downarrow & \pi \\
A & &
\end{array}
$$

lies in the $\infty$-cosmos $\text{Cart}(\mathcal{K})_A \subset \mathcal{K}_A$. This asserts firstly that $p_0: A^2 \to A$ is a cartesian fibration and secondly that $(p_1,p_0)$ defines a cartesian functor from this cartesian fibration to the cartesian fibration $\pi: A \times A \to A$ of Example 5.4.6. As observed there, $\pi$-cartesian cells are those natural transformations that whisker with the other projection to isomorphisms. Thus to say that $(p_1,p_0)$ is a cartesian functor is exactly to say that $p_1$ carries $p_0$-cartesian transformations to isomorphisms.

We now formalize these intuitions:

7.1.1. **Lemma** (cartesian on the right). For a two-sided isofibration $A \leftrightarrow E \to B$ in an $\infty$-cosmos $\mathcal{K}$, the following are equivalent:

(i) The functor

$$
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
q & \downarrow & \pi \\
A & &
\end{array}
$$

is a cartesian fibration in the slice $\infty$-cosmos $\mathcal{K}_A$.

(ii) The functor

$$
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
p & \downarrow & \pi \\
B & &
\end{array}
$$

in $\mathcal{K}_B$ lies in the sub $\infty$-cosmos $\text{Cart}(\mathcal{K})_B$.

(iii) The functor induced by $\text{id}_p$

$$
\begin{array}{ccc}
E & \xrightarrow{\text{id}_p} & \text{Hom}_B(B,p) \\
(q,p) & \downarrow & (q,p) \\
A \times B & &
\end{array}
$$

admits a right adjoint in $\mathcal{K}_{A \times B}$.

(iv) The isofibration $p: E \to B$ is a cartesian fibration in $\mathcal{K}$ and for every $p$-cartesian transformation

$$
X \xrightarrow{\eta X} E, \text{ the composite } X \xrightarrow{\psi X} E \xrightarrow{q} A \text{ is an isomorphism.}
$$
A two-sided isofibration $A \leftrightarrow E \xrightarrow{p} B$ is cartesian on the right when these equivalent conditions are satisfied.

**Proof.** We first prove that the equivalence (i)$\iff$(iii) is exactly the interpretation of the equivalence Theorem 5.2.10(i)$\iff$(ii) applied to the isofibration $(q,p): E \to A \times B$ of the $\infty$-cosmos $\mathcal{K}_A$. This latter result asserts that the isofibration $(q,p): E \to A \times B$ is a cartesian fibration in $\mathcal{K}_A$ if and only if the functor induced by $\text{id}_{(q,p)}$ from $E$ to the right representation of the functor $(q,p): E \to A \times B$ admits a right adjoint over the codomain $\pi: A \times B \to A$; since $(\mathcal{K}_A)_{/\pi}\cong \mathcal{K}_{/A \times B}$ this is the same as asserting this adjunction over $A \times B$.

The only subtlety in interpreting Theorem 5.2.10 in $\mathcal{K}_A$ has to do with the correct interpretation of the left representable comma $\infty$-category in $\mathcal{K}_A$ for the functor $(q,p): E \to A \times B$. This comma $\infty$-category is constructed as a subobject of the $\mathcal{Z}$-cotensor of the object $\pi: A \times B \to A$ in $\mathcal{K}_A$, which Proposition 1.2.22 tells us is formed as the left-hand vertical of the pullback diagram

$$
\begin{array}{ccc}
A \times B & \longrightarrow & (A \times B)^2 \\
\downarrow^{\pi} & & \downarrow^{\pi^2} \\
A & \longrightarrow & A^2
\end{array}
$$

By (3.4.2) the comma $\infty$-category is constructed by the pullback in $\mathcal{K}_A$

$$
\begin{array}{ccc}
\text{Hom}_B(B,p) & \longrightarrow & A \times B^2 \\
p_1 \downarrow & & \downarrow^{\text{id} \times p_0} \\
E & \longrightarrow & A \times B
\end{array}
\quad (7.1.2)
$$

which is created by the forgetful functor $\mathcal{K}_A \to \mathcal{K}$, and its domain-projection functor is the top composite $(qp_1,p_0): \text{Hom}_B(B,p) \to A \times B$. Now we see that the interpretation of Theorem 5.2.10(i)$\iff$(ii) in $\mathcal{K}_B$ is exactly the equivalence (i)$\iff$(iii).

It remains to demonstrate the equivalence with (ii) and (iv). Assuming (iii) and composing with $\pi: A \times B \to B$, yields a fibered adjunction that demonstrates that $p$ is a cartesian fibration. The counit of both fibered adjunctions is the same, and by Theorem 5.2.10(v) the composite

$$
\begin{array}{ccc}
\text{Hom}_B(B,p) & \longrightarrow & E \\
\downarrow^r & & \downarrow^{p_1} \\
\text{Hom}_B(B,p) & \longrightarrow & E
\end{array}
$$

is the generic $p$-cartesian cell. Since $e$ is fibered over $A \times B$, when we postcompose with $q$ we get an identity, which tells us that $q: E \to A$ carries $p$-cartesian cells to isomorphisms. This proves that (iii) implies (iv).

By Example 5.4.6, the cartesian cells for the cartesian fibration $\pi: A \times B \to B$ are precisely those 2-cells whose component with codomain $A$ is an isomorphism, so (iv) says exactly that $(q,p): E \to A \times B$ defines a cartesian functor from $p$ to $\pi$. Thus (iv) implies (ii).

242
To complete the argument, we show that (ii) implies (i). Assume (ii) and consider a 2-cell in $\mathcal{K}/A$ 

\[
\begin{array}{ccc}
X & \xrightarrow{e} & E \\
\downarrow_{(a,b)} & \searrow_{(q,p)} & \downarrow_{(q,\beta)} \\
A \times B & \rightarrow & A \\
\end{array}
\]

Because $p$ is a cartesian fibration, $\beta : b \Rightarrow pe$ has a $p$-cartesian lift $\chi : e' \Rightarrow e : X \rightarrow E$, and since $(q, p)$ is a cartesian functor, the whiskered 2-cell $q\chi : qe' \Rightarrow a$ is an isomorphism. Because $(q, p) : E \rightarrow A \times B$ is an isofibration, we may lift the 2-cell $(q\chi^{-1}, id) : (a, b) \Rightarrow e'$ to an invertible 2-cell $\gamma : e'' \Rightarrow e'$ with $p\gamma = id_b$. The composite $\chi \cdot \gamma : e'' \Rightarrow e$ is a lift of $(id, \beta)$ along $(q, p)$ over $A$, which is easily verified to satisfy the weak universal properties that characterize a $(q, p)$-cartesian lift of $(id, \beta)$ in $\mathcal{K}/A$ as established by Proposition 5.2.18. This proves (i).

The dual to Lemma 7.1.1 defines the class of two-sided isofibrations that are cocartesian on the left. Combining Lemma 7.1.1 and its dual:

7.1.3. **Corollary.** A two-sided isofibration $A \xleftarrow{q} E \xrightarrow{p} B$ is cocartesian on the left and cartesian on the right if the following equivalent conditions are satisfied:

(i) The functor 

\[
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
\downarrow_{q} & \searrow_{\pi} & \downarrow_{\pi} \\
A & \Rightarrow & B \\
\end{array}
\]

lies in coCart($\mathcal{K}$)$_{A}$ and defines a cartesian fibration in $\mathcal{K}$$_{A}$.

(ii) The functor 

\[
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
\downarrow_{p} & \swarrow_{\pi} & \downarrow_{\pi} \\
B & \Leftarrow & A \\
\end{array}
\]

lies in Cart($\mathcal{K}$)$_{B}$ and defines a cocartesian fibration in $\mathcal{K}$$_{B}$.

By Corollary 5.6.16, the comma span $C \xleftarrow{p_{1}} \text{Hom}_A(f, g) \xrightarrow{p_{0}} B$ associated to any cospan of functors

$C \xrightarrow{g} A \xleftarrow{f} B$ is both cocartesian on the left and cartesian on the right. In our motivating example $A \xleftarrow{p_{1}} A^2 \xrightarrow{p_{0}} A$ and this family of examples these structures are interrelated in a way that we now introduce. A two-sided fibration is a span that is cocartesian on the left, cartesian on the right, and satisfies a further compatibility condition that can be stated in a number of equivalent ways, which boil down to the assertion that the processes of taking $q$-cocartesian and $p$-cartesian lifts commute:

7.1.4. **Theorem.** For a two-sided isofibration $A \xleftarrow{q} E \xrightarrow{p} B$ in $\mathcal{K}$, the following are equivalent:

(i) The functor 

\[
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
\downarrow_{q} & \searrow_{\pi} & \downarrow_{\pi} \\
A & \Rightarrow & B \\
\end{array}
\]

defines a cartesian fibration in coCart($\mathcal{K}$)$_{A}$.
(ii) The functor
\[
\begin{array}{ccc}
E & \to & A \times B \\
\downarrow & & \downarrow \pi \\
B & \to & \\
\end{array}
\]
defines a cocartesian fibration in \(\text{Cart}(\mathcal{K})_B\).

(iii) The canonical functors admit the displayed adjoints in \(\mathcal{K}_{A \times B}\)
\[
\begin{array}{ccc}
E & \leftrightsquigarrow & \text{Hom}_B(B, p) \\
\downarrow & & \downarrow \\
\text{Hom}_A(q, A) & \perp & \text{Hom}_A(q, A) \times \text{Hom}_B(B, p) \\
\end{array}
\]
and the mate of the identity 2-cell in this displayed commutative square defines an isomorphism \(\ell r \cong r \ell\).

(iv) The two-sided isofibration \(A \xleftarrow{q} E \xrightarrow{p} B\) is cocartesian on the left, cartesian on the right, and satisfies a further condition: Given any pair of natural transformations as below-left together with a \(q\)-cocartesian lift \(\psi : e \Rightarrow \alpha \cdot e\) over \(B\) and a \(p\)-cartesian lift \(\chi : \beta \cdot e \Rightarrow e\) of \(\beta\) over \(A\) as below-right:
\[
\begin{array}{ccc}
A & \xleftarrow{q} & E \xrightarrow{p} B \\
\downarrow & & \downarrow \\
X & \xrightarrow{a} & B \\
\downarrow \alpha & & \downarrow \beta \\
A & \xleftarrow{q} & E \xrightarrow{p} B \\
\end{array}
\]
then there is an isomorphism \(\alpha \cdot \beta \cdot e \cong \beta \cdot \alpha \cdot e\) over \(A \times B\) commuting with the \(q\)-cocartesian lift of \(\alpha \cdot q \chi\) over \(B\) and the \(p\)-cartesian lift of \(p \psi \cdot \beta\) over \(A\).

A two-sided isofibration \(A \xleftarrow{q} E \xrightarrow{p} B\) defines a two-sided fibration from \(A\) to \(B\) when these equivalent conditions are satisfied.

PROOF. Our strategy will be to show that condition (i) is equivalent to (iii), an equationally witnessed condition in the slice \(\infty\text{-cosmos } \mathcal{K}_{A \times B}\). A dual argument will show that condition (ii) is equivalent to (iii). We then unpack this condition to prove its equivalence with (iv).

If (i) holds, then \(A \xleftarrow{q} E \xrightarrow{p} B\) also satisfies condition (i) of Corollary 7.1.3, since the property of being a cartesian fibration is preserved by the cosmological functor \(\text{coCart}(\mathcal{K})_A \hookrightarrow \mathcal{K}_A\). So \(A \xleftarrow{q} E \xrightarrow{p} B\) is in particular cocartesian on the left and cartesian on the right and is thus equipped
with adjunctions

\[
\begin{align*}
\Hom_A(q, A) & \xrightarrow{\ell} E \\
\Hom_B(B, p) & \xleftarrow{r}
\end{align*}
\]

By Lemma 3.6.6, we may pull back the left-hand adjunction along \(A \times p_1: A \times B^2 \to A \times B\) and then compose with \(A \times p_0: A \times B^2 \to A \times B\) to obtain the right-hand fibered adjunction below, and also pull back the right-hand adjunction along \(p_0 \times B: A^2 \times B \to A \times B\) and then compose with \(p_1 \times B: A^2 \times B \to A \times B\) to obtain the left-hand fibered adjunction below:

\[
\begin{align*}
\Hom_A(q, A) \times E & \xrightarrow{\ell} \Hom_B(B, p) \\
A \times B & \xleftarrow{r}
\end{align*}
\]

It remains to account for the assumption in (i) that \((q, p)\) defines a cartesian fibration in \(\text{coCart}(\mathcal{K})\) rather than merely in \(\mathcal{K}/A\). By Theorem 5.2.10(ii) this additional condition is equivalent to the assertion that the right adjoint

\[
\Hom_A(q, A) \xrightarrow{\ell} E
\]

defines a cartesian functor from the cocartesian fibration \(p_1\) to the cocartesian fibration \(q\). By Theorem 5.3.4(ii) this is equivalent to the assertion that the mate of the isomorphism in the solid-arrow square

\[
\begin{align*}
\Hom_B(B, p) & \xrightarrow{r} E \\
\Hom_A(q, A) \times E & \xleftarrow{\ell}
\end{align*}
\]

defines an isomorphism.\(^2\) This proves that (i) implies (iii).

Conversely assuming (iii), by Lemma 7.1.1 and Corollary 7.1.3 we conclude from two of the adjunctions that the functor

\[
\begin{align*}
E & \xrightarrow{(q, p)} A \times B \\
A & \xleftarrow{\pi}
\end{align*}
\]

\(^2\)The isomorphism in the solid-arrow square is the inverse of the mate that witnesses the fact that \(\text{id}_q\) defines a cartesian functor from \(p\) to \(p_0\), which is part of what it means for \((q, p)\) to be cartesian on the right.
lies in \( \text{coCart}(\mathcal{K}/A) \) and defines a cartesian fibration in \( \mathcal{K}_{/A} \). By Theorem 5.2.10(ii) it defines a cartesian fibration in \( \text{coCart}(\mathcal{K}/A) \) if and only if the right adjoint \( r \) defines a cartesian functor from \( p_1 : \text{Hom}_A(q, A) \to A \) to \( q : E \to A \); recall that the inclusion \( \text{coCart}(\mathcal{K}/A) \to \mathcal{K}_{/A} \) is full on positive dimensional arrows so there is no comparable condition on the unit and counit. By Theorem 5.3.4(ii) this follows from the invertibility of the mate \( \ell r \cong r \ell \). In this way we see that (iii) implies (i).

Thus, we have shown that condition (i) is equivalent to (iii) positing the existence of adjunctions in \( \mathcal{K}_{/A \times B} \) so that all of the mates of the solid-arrow diagram are isomorphisms. Dualizing this argument, we see that (iii) is equivalent to condition (ii).

Finally, (iii) and (iv) are equivalent since the existence of the left adjoints in (iii) is equivalent to the span being cocartesian on the left, the existence of the right adjoints is equivalent to being cartesian on the right, and the compatibility condition for the cartesian and cocartesian lifts is the meaning of the isomorphism \( \ell r \cong r \ell \).

The internal characterization of two-sided fibrations has a familiar consequence:

7.1.5. Corollary. Any two-sided isofibration \((a, b) : X \to A \times B\) that is equivalent over \( A \times B \) to a two-sided fibration \((q, p) : E \to A \times B\) is a two-sided fibration.

Proof. The assertion of Theorem 7.1.4(iii) is invariant under fibered equivalence.

Theorem 7.1.4 will help us establish an important family of examples involving the ordinal categories from Definition 1.1.4.

7.1.6. Proposition. For any \( \infty \)-category \( A \) and any \( n \geq 2 \), the two-sided isofibration \( A \overset{p_{n-1}} \leftarrow A^n \overset{p_0} \to A \) defines a two-sided fibration.

This result is a generalization of Proposition 5.2.16 and its dual and the proof uses similar ideas.

Proof. We use Theorem 7.1.4(iii). The right representable comma \( \infty \)-category associated to the evaluation at the initial object \( p_0 : A^n \to A \) is constructed by the pullback

\[
\begin{array}{ccc}
A^{2 \vee n} & \longrightarrow & A^2 \\
\downarrow & & \downarrow p_1 \\
A^n & \longrightarrow & A
\end{array}
\]

which is equivalent to \( (p_{n-1}, p_0) : A^{n+1} \to A \times A \) over the endpoint evaluation maps. The canonical functor that tests whether \( (p_{n-1}, p_0) : A^n \to A \times A \) is cartesian on the right is given by restriction along the epimorphism \( \sigma^0 : n + 1 \to n \) that sends the objects \( 0, 1 \in n + 1 \) to \( 0 \in n \). This functor admits a left adjoint under the endpoint inclusions

which provides the desired fibered right adjoint displayed above left.

\[246\]
A dual argument shows that \( (p_{n-1}, p_0) : A^n \to A \times A \) is cocartesian on the left. The final condition asks that the mate of the commutative square defined by the degeneracy maps

\[
\begin{array}{cccc}
\delta^1 & 1 & \delta^1 \\
\delta^n & \sigma^n & \sigma^{n+1} & \delta^{n+1} \\
\delta^1 & 1 & \delta^1 \\
\delta^n & \sigma^n & \sigma^{n+1} & \delta^{n+1} \\
\end{array}
\]

is an isomorphism, encoding one of the familiar simplicial identities. The square in Theorem 7.1.4(iii) is obtained by applying \( A^{(-)} \).

We defer further discussion of the closure properties of the class of two-sided fibrations to the next section, where we deploy cosmological arguments to streamline their proofs. These observations will allow us to enlarge our family of examples.

To prepare for that work, we need to consider the structure-preserving morphisms between two-sided fibrations, proving a relative analogue of Theorem 7.1.4:

**7.1.7. Proposition.** For map of spans between a pair of two-sided fibrations from \( A \) to \( B \) in an \( \infty \)-cosmos

\[
\begin{array}{cccc}
A & E & B \\
q & h & p \\
s & r & F
\end{array}
\]

the following are equivalent:

(i) \( h \) defines a cartesian functor between the cartesian fibrations in \( \text{coCart}(\mathcal{K})_A \).

(ii) \( h \) defines a cartesian functor between the cocartesian fibrations in \( \text{Cart}(\mathcal{K})_B \).

(iii) The mates of the canonical isomorphisms

\[
\begin{array}{cccc}
E & h & F \\
\ell & \cong & \ell \\
\ell & \cong & \ell \\
\end{array}
\]

\[
\begin{array}{cccc}
E & h & F \\
\ell & \cong & \ell \\
\ell & \cong & \ell \\
\end{array}
\]

\[
\begin{array}{cccc}
\text{Hom}_A(q, A) & \cong & \text{Hom}_A(s, A) \\
\text{Hom}_B(B, p) & \cong & \text{Hom}_B(B, r) \\
\end{array}
\]

define isomorphisms in \( \mathcal{K}_{/A \times B} \).

(iv) \( h \) defines a cartesian functor between the cocartesian fibrations \( q \) and \( s \) and also a cartesian functor between the cartesian fibrations \( p \) and \( r \) in \( \mathcal{K} \).

The map of spans (7.1.8) defines a cartesian functor between two-sided fibrations from \( A \) to \( B \) when these equivalent conditions are satisfied.

**Proof.** By Theorem 5.3.4(ii),(iii) is equivalent to demanding that the two mates on display in (iii) are isomorphisms in \( \mathcal{K}_{/A} \) and \( \mathcal{K}_{/B} \) respectively. But since the spans are two-sided fibrations from \( A \) to \( B \) and \( h \) is a map over \( A \times B \), both natural transformations lie in \( \mathcal{K}_{/A \times B} \). By Proposition 3.6.2, if these natural transformations admit inverses in \( \mathcal{K}_{/A} \) and \( \mathcal{K}_{/B} \), then these inverse transformations lift to an inverse isomorphism in \( \mathcal{K}_{/A \times B} \). This proves that (iii) is equivalent to (iii).
We next prove that (i) is equivalent to (iii). The proof of the equivalence of (ii) and (iii) is dual. To assert, as in (i) that the map 

\[ \begin{array}{ccc}
E & \xrightarrow{h} & F \\
\downarrow \scriptstyle{\text{id}_q} & \cong & \downarrow \scriptstyle{\text{id}_s} \\
\Hom_A(q, A) & \cong & \Hom_A(s, A)
\end{array} \]

defines a cartesian functor between cartesian fibrations in \( \text{coCart}(\mathcal{K})/A \), means firstly that the mate

\[ h \downarrow \scriptstyle{\text{id}_q} \quad \cong \quad \downarrow \scriptstyle{\text{id}_s} \]

defines an isomorphism in \( \mathcal{K}/A \), because \( h \) defines a cartesian functor between the cocartesian fibrations \( q \) and \( s \), over \( A \) and secondly that the mate

\[ \begin{array}{ccc}
E & \xrightarrow{h} & F \\
\downarrow \scriptstyle{\text{id}_p} & \cong & \downarrow \scriptstyle{\text{id}_r} \\
\Hom_B(B, p) & \cong & \Hom_B(B, r)
\end{array} \]

is an isomorphism in \( \text{coCart}(\mathcal{K})/A \) \( / \pi \). Since the spans are two-sided fibrations and \( h \) is a map over \( A \times B \), the first pair of mates lies in \( \mathcal{K}/A \times B \). And since the inclusion \( \text{coCart}(\mathcal{K})/A \) \( / \pi \hookrightarrow \mathcal{K}/A \times B \) is full on positive-dimensional arrows, to ask that the second pair of mates are isomorphisms in \( \text{coCart}(\mathcal{K})/A \) \( / \pi \) is equivalent to asking the same condition in \( \mathcal{K}/A \times B \). This proves the equivalence with (iii).

It follows from the internal characterizations of Theorem 7.1.4 and Proposition 7.1.7.

7.1.9. Corollary. Any cosmological functor preserves two-sided fibrations and cartesian functors between them.

Proof. By Proposition 1.3.3(vi) any cosmological functor \( F: \mathcal{K} \rightarrow \mathcal{L} \) induces a cosmological functor \( F: \mathcal{K}/A \times B \rightarrow \mathcal{L}/F/A \times F/B \) for any pair of \( \infty \)-categories \( A \) and \( B \) in \( \mathcal{K} \). This functor preserves the fibered adjunctions and invertible mates of Theorem 7.1.4(iii). Thus \( F: \mathcal{K} \rightarrow \mathcal{L} \) preserves two-sided fibrations. Similarly, any cosmological functor preserves the invertible mates of Proposition 7.1.7(iii).

Exercises.

7.1.i. Exercise. Prove that

(i) A two-sided isofibration \( 1 \xleftarrow{p} E \xrightarrow{p} B \) defines a two-sided fibration from 1 to \( B \) if and only if \( p: E \rightarrow B \) is a cartesian fibration.
(ii) A map of spans

\[
\begin{array}{c}
1 \\
\downarrow h \\
E \xrightarrow{p} B
\end{array}
\]

defines a cartesian functor of two-sided fibrations if and only if \( h : E \to F \) defines a cartesian functor from \( p \) to \( q \).

7.1.ii. Exercise. Suppose \( A \leftarrow E \rightarrow B \) and \( A \leftarrow F \rightarrow B \) are two-sided fibrations and \( \alpha : h \cong h' \) is a fibered natural isomorphism

\[
\begin{array}{c}
A \\
\downarrow s \\
E \xrightarrow{p} B
\end{array}
\xrightarrow{\alpha} \xrightarrow{h} \xleftarrow{h'} \xleftarrow{r} \xrightarrow{q} \xrightarrow{s} \xrightarrow{r} \xrightarrow{F}
\]

so that \( r\alpha = \text{id}_p \) and \( s\alpha = \text{id}_q \); in particular, \( h \) and \( h' \) each define maps of spans. Show that \( h \) is a cartesian functor if and only if \( h' \) is a cartesian functor.

7.2. The \( \infty \)-Cosmos of Two-Sided Fibrations

The first pair of equivalent conditions of Theorem 7.1.4 and Proposition 7.1.7 provide two equivalent ways to define the \( \infty \)-cosmos of two-sided fibrations, using the \( \infty \)-cosmoi of Proposition 6.4.13.

7.2.1. Definition (the \( \infty \)-cosmos of two-sided fibrations). By Theorem 7.1.4 and Proposition 7.1.7, for any \( \infty \)-categories \( A \) and \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \) the pair of quasi-categorically enriched subcategories

\[
\text{Cart}(\text{coCart}(\mathcal{K})/_{\pi : A \times B \to A}) \quad \text{and} \quad \text{coCart}(\text{Cart}(\mathcal{K})/_{\pi : A \times B \to B})
\]

of \( \mathcal{K}_{/A \times B} \) coincide. We write

\[
A_{/\mathcal{K}/B} \subset \mathcal{K}_{/A \times B}
\]

for this common subcategory and refer to it as the \( \infty \)-cosmos of two-sided fibrations from \( A \) to \( B \), employing terminology we will justify momentarily.

By definition

\[
\text{Fun}_{A_{/\mathcal{K}/B}}(E, F) := \text{Fun}_{A \times B}(E, F) \subset \text{Fun}_{A \times B}(E, F)
\]

is the quasi-category of maps of spans that define cartesian functors from \( E \) to \( F \) in the sense of Proposition 7.1.7.

Since a two-sided isofibration from \( A \) to \( B \) is simply an isofibration over \( A \times B \), we may refer to \( \mathcal{K}_{/A \times B} \) as the \( \infty \)-cosmos of two-sided isofibration from \( A \) to \( B \).

7.2.2. Proposition. For any \( \infty \)-categories \( A \) and \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \), \( A_{/\mathcal{K}/B} \subset \mathcal{K}_{/A \times B} \) is a cosmologically embedded \( \infty \)-cosmos, with the inclusion creating an \( \infty \)-cosmos structure on the \( \infty \)-cosmos of two-sided fibrations from the \( \infty \)-cosmos of two-sided isofibrations.

Proof. This inclusion factors as

\[
A_{/\mathcal{K}/B} \equiv \text{coCart}(\text{Cart}(\mathcal{K})/_{A \times B \to A}) \hookrightarrow (\text{Cart}(\mathcal{K})/_{A \times B \to B}) \hookrightarrow (\mathcal{K}/_{A \times B \to B}) \equiv \mathcal{K}_{/A \times B}
\]

and by Proposition 6.4.13, both inclusions are cosmological embeddings. \( \square \)
7.2.3. Observation (two-sided fibrations generalize (co)cartesian fibrations). By Exercise 7.1.i, a two-sided fibration from \(B\) to \(1\) is a cocartesian fibration over \(B\), while a two-sided fibration from \(1\) to \(B\) is a cartesian fibration over \(B\). Indeed, as \(\infty\)-cosmoi

\[
\text{coCart}(\mathcal{K})/\mathbb{B} \cong \mathcal{B}\text{Fib}(\mathcal{K})/1 \quad \text{and} \quad \text{Cart}(\mathcal{K})/\mathbb{B} \cong \mathcal{1}\text{Fib}(\mathcal{K})/\mathbb{B}.
\]

In this sense, statements about two-sided fibrations simultaneously generalize statements about cartesian and cocartesian fibrations.

We now turn our attention to the promised closure properties:

7.2.4. Proposition. For any pair of functors \(a: A' \to A\) and \(b: B' \to B\), the cosmological pullback functor restricts to define a cosmological functor

\[
\begin{array}{ccc}
A\text{Fib}(\mathcal{K})/B & \xrightarrow{(a, b)^*} & \mathcal{K}/A \times B' \\
\downarrow (a, b)^* & & \downarrow b^* \\
A\text{Fib}(\mathcal{K})/B' & \xrightarrow{b^*} & \mathcal{K}/B'
\end{array}
\]

In particular, the pullback of a two-sided fibration is again a two-sided fibration.

Proof. By factoring the functor \((a, b)\) as \(A' \times B' \xrightarrow{id \times b} A' \times B \xrightarrow{a \times id} A \times B\) we see that it suffices to consider pullback along one side at a time. Proposition 5.2.4 proves that pullback along \(b: B' \to B\) preserves cartesian fibrations and Exercise 5.3.i extends this to cartesian functors, defining a restricted functor

\[
\begin{array}{ccc}
\text{Cart}(\mathcal{K})/B & \xrightarrow{b^*} & \mathcal{K}/B \\
\downarrow b^* & & \downarrow b^* \\
\text{Cart}(\mathcal{K})/B' & \xrightarrow{b^*} & \mathcal{K}/B'
\end{array}
\]

Since limits and isofibrations in \(\text{Cart}(\mathcal{K})/B\) are created in \(\mathcal{K}/B\), this restricted functor is a cosmological functor. Applying this result to the map

\[
\begin{array}{ccc}
A \times B' & \xrightarrow{id \times b} & A \times B \\
\downarrow \pi & & \downarrow \pi \\
A & \xleftarrow{\pi} & A
\end{array}
\]

in the \(\infty\)-cosmos \(\text{coCart}(\mathcal{K})/A\), we conclude that pullback restricts to define a cosmological functor

\[
\begin{array}{ccc}
A\text{Fib}(\mathcal{K})/B & \xrightarrow{(id \times b)^*} & \mathcal{K}/A \times B' \\
\downarrow (id \times b)^* & & \downarrow (id \times b)^* \\
A\text{Fib}(\mathcal{K})/B' & \xrightarrow{(id \times b)^*} & \mathcal{K}/A \times B'
\end{array}
\]

\(\square\)

7.2.5. Lemma. If \(A \xleftarrow{q} E \xrightarrow{p} B\) is a two-sided fibration from \(A\) to \(B\), \(v: A \to C\) is a cocartesian fibration and \(u: B \to D\) is a cartesian fibration, then the composite span

\[
C \xleftarrow{v} A \xleftarrow{q} E \xrightarrow{p} B \xrightarrow{u} D
\]

250
defines a two-sided fibration from $C$ to $D$. Moreover, a cartesian functor between two-sided fibrations from $A$ to $B$ induces a cartesian functor

\[
\begin{array}{c}
A \\
\downarrow v \\
\downarrow h \\
B \\
\downarrow u \\
D
\end{array}
\]

between two-sided fibrations from $C$ to $D$.

Note composition in the sense being described here does not define a cosmological functor from $A/Fib(K)/B$ to $C/Fib(K)/D$ because it does not preserve flexible weighted limits.

**Proof.** By Theorem 7.1.4, it suffices to consider composition on one side at a time, say with a cocartesian fibration $v : A \to C$. Working in the $\infty$-cosmos $Cart(K)/B$, we are given cocartesian fibrations

\[
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
\downarrow p & & \downarrow \pi \\
B & & \downarrow \pi \\
F & & \downarrow \pi
\end{array}
\quad \quad \quad
\begin{array}{ccc}
A \times B & \xrightarrow{v \times \text{id}} & C \times B \\
\downarrow \pi & & \downarrow \pi \\
B & & \downarrow \pi
\end{array}
\]

These compose to define a cocartesian fibration

\[
\begin{array}{c}
E \\
\downarrow p \\
B \\
\downarrow \pi \\
C \times B
\end{array}
\]

and hence a two-sided fibration from $C$ to $B$, as desired.

By Lemma 5.2.3, the $vq$-cocartesian cells are the $q$-cocartesian lifts of the $v$-cocartesian cells. If $h$ is a cartesian functor from $q$ to $s$, then these are clearly preserved, proving that $h$ also defines a cartesian functor from $vq$ to $vs$. By Proposition 7.1.7(iv) this proves that $h$ defines a cartesian functor between the whiskered two-sided fibrations. \qed

Proposition 7.2.4 and Lemma 7.2.5 combine to prove that two-sided fibrations can be composed “horizontally.”

**7.2.6. Proposition.** The pullback of a two-sided fibration from $A$ to $B$ along a two-sided fibration from $B$ to $C$

\[
\begin{array}{c}
E \times F \\
\downarrow \pi_1 \\
A \\
\downarrow p \\
B \\
\downarrow s \\
F \\
\downarrow r \\
C
\end{array}
\]

defines a two-sided fibration from $A$ to $C$ as displayed.
**Proof.** The composite two-sided fibration is constructed in two stages, first by pulling back

\[
\begin{array}{c}
E \times F \\
\downarrow \downarrow \downarrow \\
B \ F \\
\downarrow \downarrow \downarrow \\
E \times C \\
\downarrow \downarrow \downarrow \\
B \times C
\end{array}
\]

and then by composing the left leg with the cocartesian fibration \( q: E \rightarrow A \). By Proposition 7.2.4 and Lemma 7.2.5, this results is a two-sided fibration from \( A \) to \( C \). Alternatively, the composite can be constructed by pulling back along \( A \times s \) and composing with the cartesian fibration \( r: F \rightarrow C \), resulting in another two-sided fibration from \( A \) to \( C \) that is canonically isomorphic to the first. \( \square \)

With these results in hand, we may add to our library of examples:

**7.2.7. Example.** If \( p: E \rightarrow B \) is a cartesian fibration and \( q: F \rightarrow A \) is a cocartesian fibration, then the span

\[
A \leftarrow F \leftarrow F \times E \rightarrow E \rightarrow B
\]

defines a two-sided fibration from \( A \) to \( B \).

**7.2.8. Example.** By Proposition 7.1.6 and Proposition 7.2.4, a general comma span

\[
C \leftarrow \text{Hom}_A(f, g) \rightarrow B
\]

is a two-sided fibration, as a pullback of \( A \leftrightarrow A^2 \rightarrow A \).

**7.2.9. Example.** By Proposition 7.2.6, “horizontal composites” of comma spans are also two-sided fibrations. For instance, the two-sided fibrations \( A \leftarrow A^{n+1} \rightarrow A \) are \( n \)-ary horizontal composites of the arrow span \( A \leftrightarrow A^2 \rightarrow A \).

Other two-sided fibrations we will soon have occasion to consider include the horizontal composite associated to a cospan \( C \rightarrow A \leftarrow B \)

\[
\begin{array}{c}
\text{Hom}_A(A, g) \times \text{Hom}_A(f, A) \\
\downarrow \downarrow \downarrow \\
C \rightarrow A \leftarrow B
\end{array}
\]

and the horizontal composite associated to a span \( A \leftarrow X \rightarrow B \)

\[
\begin{array}{c}
\text{Hom}_A(a, A) \times \text{Hom}_B(B, b) \\
\downarrow \downarrow \downarrow \\
A \rightarrow X \leftarrow B
\end{array}
\]
Exercises.

7.2.i. Exercise. Consider a diagram

\[
\begin{array}{ccc}
A & \xrightarrow{p} & E \\
& \searrow{q} & \downarrow{h} & \swarrow{q'} \\
E' & \xrightarrow{p'} & B \\
& \searrow{s'} & \downarrow{s} & \swarrow{r'} \\
& \downarrow{k} & \downarrow{r} & \\
B' & \xrightarrow{k} & C \\
\end{array}
\]

in which \(h\) and \(k\) define cartesian functors between two-sided fibrations, from \(A\) to \(B\) and from \(B\) to \(C\), respectively. Prove that \(h\) and \(k\) pullback to define a cartesian functor \((h, k): E \times_B F \to E' \times_B F'\) between two-sided fibrations from \(A\) to \(C\).

7.2.ii. Exercise. Prove the assertion made in Example 7.2.7.

7.3. Representable Two-Sided Fibrations and the Yoneda Lemma

We now introduce representable two-sided fibrations and prove a two-sided version of the Yoneda lemma.

7.3.1. Definition. By the construction of Example 7.2.9, for any pair of generalized elements \(a: X \to A\) and \(b: X \to B\), the span

\[
\begin{array}{ccc}
A & \xleftarrow{p_1} & \text{Hom}_A(a, A) \times_{X} \text{Hom}_B(B, b) \\
& \xrightarrow{p_0} & B \\
\end{array}
\]

defines a two-sided fibration from \(A\) to \(B\) that we refer to as the two-sided fibration represented by \(a\) and \(b\). As was the case for one-sided representables, there is a canonical generalized element \((\text{id}_a^\triangleright, \text{id}_b^\triangleright): X \to \text{Hom}_A(a, A) \times_{X} \text{Hom}_B(B, b)\) in the fiber over \((a, b): X \to A \times B\).

The terminology of Definition 7.3.1 is justified by the Yoneda lemma for two-sided fibrations, which we prove using the Yoneda lemma for generalized elements of Corollary 5.7.23.

7.3.2. Theorem (Yoneda lemma). For any pair of generalized elements \(a: X \to A\) and \(b: X \to B\) and any two-sided fibration \(A \leftarrow E \rightarrow B\), restriction along \((\text{id}_a^\triangleright, \text{id}_b^\triangleright): X \to \text{Hom}_A(a, A) \times_{X} \text{Hom}_B(B, b)\) defines an equivalence of quasi-categories

\[
\text{ev}_{(\text{id}_a^\triangleright, \text{id}_b^\triangleright)}: \text{Fun}_{A \times B}^\text{cart} \left( \begin{array}{ccc}
\text{Hom}_A(a, A) \times_{X} \text{Hom}_B(B, b) & E \\
(\text{id}_a^\triangleright, \text{id}_b^\triangleright) & (a, b) \\
A \times B & A \times B \\
\end{array} \right) \xrightarrow{\sim} \text{Fun}_{A \times B} \left( \begin{array}{ccc}
X & E \\
(\text{id}_a^\triangleright, \text{id}_b^\triangleright) & (a, b) \\
A \times B & A \times B \\
\end{array} \right).
\]

Proof. We prove this result using the perspective of Theorem 7.1.4(i), considering the target two-sided fibration \(A \leftarrow E \rightarrow B\) in an \(\infty\)-cosmos \(\mathcal{K}\) as a cartesian fibration over \(\pi: A \times B \to A\) in the \(\infty\)-cosmos \(\text{coCart}(\mathcal{K})_{/A \times B}\). We deduce this result by applying the Yoneda lemma for generalized elements of Corollary 5.7.23 twice: first for cartesian fibrations over \(\pi: A \times B \to A\) in \(\text{coCart}(\mathcal{K})_{/A}\) and then for cocartesian fibrations over \(A\) in \(\mathcal{K}\).
To prepare for the first application of Yoneda, we need to produce a generalized element with codomain \( \pi : A \times B \to A \) in \( \text{coCart}(\mathcal{K})/A \) from the map

\[
\begin{array}{ccc}
X & \xrightarrow{(a,b)} & A \times B \\
\downarrow & \searrow_{a} & \swarrow_{\pi} \\
A & & \\
\end{array}
\]

over \( A \). Corollary 5.7.23 supplies an equivalence

\[
\text{Fun}^\text{cart}_A(\text{Hom}_A(a, A) \xrightarrow{p_1} A, A \times B \xrightarrow{\pi} A) \xrightarrow{\text{ev}_{id\_a}} \text{Fun}_A(X \xrightarrow{a} A, A \times B \xrightarrow{\pi} A)
\]

which tells us that the reflection of \( a : X \to A \) into \( \text{coCart}(\mathcal{K})/A \) is given by \( p_1 : \text{Hom}_A(a, A) \to A \). So we take our generalized element to be the cartesian functor

\[
\text{Hom}_A(a, A) \xrightarrow{(p_1, b_p_0)} A \times B \xrightarrow{\pi} A
\]

between cocartesian fibrations over \( A \).

By Corollary 5.7.23 once more, the reflection of the object (7.3.3) of \( (\text{coCart}(\mathcal{K})/A)_{\pi} : A \times B \to A \) into \( A/\mathcal{Fib}_B \) is given by the codomain projection from its right comma representation, formed in \( \text{coCart}(\mathcal{K})/A \). This recovers exactly the two-sided fibration

\[
\text{Hom}_A(a, A) \times \text{Hom}_B(B, b) \xrightarrow{(p_1, p_0, \pi_0)} A \times B
\]

Thus, that result supplies an equivalence

\[
\text{cv}_{(id, id\_a \_0)} : \text{Fun}^\text{cart}_{A \times B}(\text{Hom}_A(a, A) \times \text{Hom}_B(B, b), E) \xrightarrow{\text{ev}_{id\_a \_0}} \text{Fun}^\text{cart}_{A \times B}(\text{Hom}_A(a, A) \times \text{Hom}_B(B, b), E) \xrightarrow{\text{Fun}^\text{cart}_{A \times B}(\text{Hom}_A(a, A), E) \xrightarrow{p_1} A, E \xrightarrow{q} A)
\]

where the right-hand functor space is defined by the pullback

\[
\begin{array}{ccc}
\text{Fun}^\text{cart}_{A \times B}(\text{Hom}_A(a, A), E) & \xrightarrow{(p_1, b_p_0)} & \text{Fun}^\text{cart}_A(\text{Hom}_A(a, A) \xrightarrow{p_1} A, A \times B \xrightarrow{\pi} A) \\
\downarrow & \downarrow_{(q, p)_*} & \downarrow \searrow_{(q, p)_*} \\
\text{Fun}^\text{cart}_A(\text{Hom}_A(a, A) \xrightarrow{p_1} A, A \times B \xrightarrow{\pi} A) & & \\
\end{array}
\]
of functor spaces in \( \text{coCart}(\mathcal{K})_{/A} \). The Yoneda lemma of Corollary 5.7.23 again supplies natural equivalences

\[
\begin{align*}
\text{Fun}^\text{cart}_A(\text{Hom}_A(a, A) \xrightarrow{p_1} A, E \xrightarrow{q} A) & \xrightarrow{\text{ev}_{\text{id}_a}^\gamma} \text{Fun}_A(X, E) \\
\downarrow (q,p)_* & \\
\text{Fun}^\text{cart}_A(\text{Hom}_A(a, A) \xrightarrow{p_1} A, A \times B \xrightarrow{\pi} A) & \xrightarrow{\text{ev}_{\text{id}_a}^\gamma} \text{Fun}_A(X, A \times B) \\
\downarrow (q,p)_* & 
\end{align*}
\]

inducing an equivalence from the quasi-category \( \text{Fun}^\text{cart}_{A \times B}(\text{Hom}_A(a, A), E) \) of maps of spans from \( \text{Hom}_A(a, A) \) to \( E \) that define cartesian functors between the left legs to the pullback

\[
\begin{align*}
\text{Fun}_{A \times B}(X, E) & \longrightarrow \text{Fun}_A(X, E) \\
\downarrow \delta & \\
\text{Fun}_{A \times B}(X, A \times B) & \longrightarrow \text{Fun}(X, A \times B) \\
\downarrow (q,p)_* & \\
\text{Fun}_A(X, A) & \longleftarrow \text{Fun}(X, A)
\end{align*}
\]

To see that this pullback is isomorphic to the quasi-category \( \text{Fun}_{A \times B}(X, E) \), observe that the right-hand isofibration is itself a pullback

\[
\begin{align*}
\text{Fun}_A(X, E) & \xrightarrow{\delta} \text{Fun}(X, E) \\
\downarrow & \\
\text{Fun}_A(X, A \times B) & \xrightarrow{\pi_*} \text{Fun}(X, A \times B) \\
\downarrow & \\
\text{Fun}_A(X, A) & \longleftarrow \text{Fun}(X, A)
\end{align*}
\]

This composite equivalence is the map defined by precomposition with the canonical generalized element

\[
(\langle \text{id}_a^\gamma, \text{id}_b^\gamma \rangle) : X \to \text{Hom}_A(a, A) \times \text{Hom}_B(b, b),
\]

completing the proof. \( \square \)

7.3.4. REMARK. As in Corollary 5.7.23, we interpret Theorem 7.3.2 as defining a left biadjoint to the inclusion

\[
A_\text{Fib} \hookrightarrow \mathcal{K}_{/A \times B}
\]

defined by sending a two-sided isofibration \( A \xleftarrow{a} X \xrightarrow{b} B \) to the composite two-sided fibration

though as observed in the proof, the equivalence of functor spaces can be defined for any pair of generalized elements \( a : X \to A \) and \( b : X \to B \), whether or not this span defines a two-sided isofibration.

In the case of spans represented by a single non-identity functor a “one-sided” version of Theorem 7.3.2, which is much more simply established, may be preferred:
7.3.5. Proposition (one-sided Yoneda for two-sided fibrations). For any two-sided isofibration \( A \xleftarrow{q} E \xrightarrow{p} B \) and functor \( f : A \to B \), restriction along the canonical functor

\[
\begin{tikzcd}
A 
& B \\
\Hom_B(B, f) 
& \Hom_B(B, f) 
\end{tikzcd}
\]

induce equivalences of functor spaces

\[
\begin{pmatrix}
\Hom_B(B, f) \\
A \times B
\end{pmatrix}
\xrightarrow{\text{restriction}}
\begin{pmatrix}
\Hom_B(B, f) \\
A \times B
\end{pmatrix}
\xrightarrow{\text{functor}}
\begin{pmatrix}
A \\
E
\end{pmatrix}
\xrightarrow{\text{restriction}}
\begin{pmatrix}
A \\
E
\end{pmatrix}
\]

**Proof.** This follows immediately from the Yoneda lemma of Theorem 5.7.6 applied to the element \((\text{id}, f) : A \to A \times B\) and the cartesian fibration \((q, p) : E \to A \times B\) in the \(\infty\)-cosmos \(\text{coCart}(\mathcal{K})_A\). \(\square\)

**Exercises.**
7.3.i. Exercise. State and prove the other one-sided Yoneda lemma for two-sided fibrations, establishing an equivalence of functor spaces below-left induced by restricting along the functor below-right

\[
\begin{pmatrix}
\Hom_A(f, A) \\
A \times B
\end{pmatrix}
\xrightarrow{\text{restriction}}
\begin{pmatrix}
\Hom_A(f, A) \\
A \times B
\end{pmatrix}
\xrightarrow{\text{functor}}
\begin{pmatrix}
B \\
E
\end{pmatrix}
\xrightarrow{\text{restriction}}
\begin{pmatrix}
B \\
E
\end{pmatrix}
\]

7.4. Modules as Discrete Two-Sided Fibrations

We now turn our attention to a special property of certain two-sided fibrations, such as comma spans, which are discrete as objects in a sliced \(\infty\)-cosmos.

7.4.1. Definition. A **module from** \(A\) **to** \(B\) in an \(\infty\)-cosmos \(\mathcal{K}\) is a two-sided fibration \( A \xleftarrow{q} E \xrightarrow{p} B \) that is a discrete object in \(A\backslash\text{Fib}(\mathcal{K})_B\).

Note that an object in the cosmologically embedded \(\infty\)-cosmos \(A\backslash\text{Fib}(\mathcal{K})_B \hookrightarrow \mathcal{K}_{A \times B}\) is discrete in there if and only if it is discrete as an object of \(\mathcal{K}_{A \times B}\); see Exercise 6.4.v. Our work in this chapter enables us to give a direct characterization of modules:

7.4.2. Proposition. A two-sided isofibration \( A \xleftarrow{q} E \xrightarrow{p} B \) defines a module from \(A\) to \(B\) if and only if it is

(i) cocartesian on the left,

(ii) cartesian on the right,

(iii) and discrete as an object of \(\mathcal{K}_{A \times B}\).
Proof. Comparing Definition 7.4.1 with the statement, we see that we need only argue that these three properties suffice to prove that \( E \) is a two-sided fibration from \( A \) to \( B \). Theorem 7.1.4(iv) tells us that a two-sided fibration \( E \) from \( A \) to \( B \) in \( \mathcal{K} \) is a two-sided isofibration that is cocartesian on the left, cartesian on the right, and for which a certain natural transformation with codomain \( E \) in \( \mathcal{K}_{/A \times B} \) is an isomorphism. When \( E \) is a discrete object in \( \mathcal{K}_{/A \times B} \) all natural transformations with codomain \( E \) are invertible, so properties (i), (ii), and (iii) suffice. \( \square \)

The following properties of modules are easily deduced from our results about two-sided fibrations.

7.4.3. Lemma. If \( A \xleftarrow{q} E \xrightarrow{p} B \) defines a module from \( A \) to \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \), then

(i) The functors
\[
\begin{array}{ccc}
E & \xrightarrow{(q,p)} & A \times B \\
\downarrow{p} & & \downarrow{\pi} \\
B & \xleftarrow{\pi} & A
\end{array}
\]
define a discrete cocartesian fibration and a discrete cartesian fibration, respectively, in the \( \infty \)-cosmos \( \text{Cart}(\mathcal{K})_B \) and \( \text{coCart}(\mathcal{K})_A \).

(ii) The functors \( q: E \to A \) and \( p: E \to B \) respectively define a cocartesian fibration and a cartesian fibration in \( \mathcal{K} \).

(iii) For any 2-cell \( \psi \) with codomain \( E \), \( \psi \) is \( p \)-cartesian if and only if \( q\psi \) is invertible, and \( \psi \) is \( q \)-cocartesian if and only if \( p\psi \) is invertible.

(iv) In particular, any 2-cell that is fibered over \( A \times B \) is both \( p \)- and \( q \)-cocartesian and any map of spans from a two-sided fibration
\[
\begin{array}{ccc}
A & \xleftarrow{s} & F & \xrightarrow{r} & B \\
\downarrow{q} & & \downarrow{g} & & \downarrow{p} \\
E & \xrightarrow{r} & B
\end{array}
\]
to a module defines a cartesian functor of two-sided fibrations, and also a cartesian functor from \( s \) to \( q \) and from \( r \) to \( p \).

Proof. By Lemma 7.1.1, conditions (ii) and (iii) of Proposition 7.4.2 combine to tell us that the two-sided isofibration \( (q,p): E \to A \times B \) defines a discrete cartesian fibration in \( \mathcal{K}_{/A} \). Since modules are two-sided fibrations and discreteness is reflected by cosmological embeddings, in fact \( (q,p): E \to A \times B \) defines a discrete cartesian fibration in \( \text{coCart}(\mathcal{K})_{/A} \), proving (i).

Statement (ii) holds for any two-sided fibration; the point of reasserting it here is that it is not necessarily the case that the legs of a module are themselves discrete fibrations (see Exercise 7.4.i).

One direction of statement (iii) is proven as Lemma 7.1.1(iv). For the converse, consider a natural transformation \( \psi \) with codomain \( E \) and suppose \( q\psi \) is invertible. Composing with a lift of \( q\psi^{-1} \) along the isofibration \( q: E \to A \), we see that \( \psi \) is isomorphic to a natural transformation \( \psi' \) with \( q\psi' \) an identity. By isomorphism stability of \( p \)-cartesian transformations, it suffices to prove that \( \psi' \) is \( p \)-cartesian. By Proposition 3.6.2, \( \psi' \) can be lifted along the smothering 2-functor \( \mathcal{h}(\mathcal{K}_{/A}) \to (\mathcal{h}\mathcal{K})_{/A} \) to a natural transformation in the sliced \( \infty \)-cosmos \( \mathcal{K}_{/A} \) with codomain \( q: E \to A \); as we typically perform such liftings without comment, we retain the notation \( \psi' \) for the fibered natural transformation in \( \mathcal{K}_{/A} \).

Since \( (q,p): E \to A \times B \) is a discrete cartesian fibration in \( \mathcal{K}_{/A} \), every such natural transformation is \( (q,p) \)-cartesian. By Theorem 5.2.10(v), it follows that \( \psi' \) is isomorphic to a whiskered copy of the
counit of the fibered adjunction \( \gamma \text{id}_p \to r \) over \( A \times B \). As the same data, regarded this time as a fibered adjunction over \( B \), witnesses the fact that \( p : E \to B \) is a cartesian fibration. Theorem 5.2.10(v) also tells us that \( \psi' \) and thus \( \psi \) is \( p \)-cartesian, as claimed.

Statement (iv) follows from (iii) and Proposition 7.1.7(iv).

We have seen that the modules are exactly the discrete objects in the \( \infty \)-cosmos of two-sided fibrations. Hence:

**7.4.4. Corollary.** For any \( \infty \)-categories \( A \) and \( B \) in an \( \infty \)-cosmos \( \mathcal{K} \), there is a cosmologically embedded \( \infty \)-cosmos

\[
\begin{array}{ccc}
A \backslash \text{Mod} (\mathcal{K})_{/B} & 
\xleftarrow{\mathcal{K}_{/A \times B}} & 
A \backslash \text{Fib} (\mathcal{K})_{/B} \\
\end{array}
\]

defined as a full subcategory of either the \( \infty \)-cosmos of two-sided fibrations from \( A \) to \( B \) or of the \( \infty \)-cosmos of isofibrations from \( A \) to \( B \).

**Proof.** Proposition 6.1.6 proves that \( A \backslash \text{Mod} (\mathcal{K})_{/B} \hookrightarrow A \backslash \text{Fib} (\mathcal{K})_{/B} \) is a cosmologically embedded \( \infty \)-cosmos of the \( \infty \)-cosmos of Proposition 7.2.2, while Lemma 7.4.3(iv) proves that the inclusion \( A \backslash \text{Mod} (\mathcal{K})_{/B} \hookrightarrow \mathcal{K}_{/A \times B} \) is also full.

An important property of modules is that they are stable under pullback:

**7.4.5. Proposition.** If \( A \leftarrow E \to B \) is a module from \( A \) to \( B \) and \( a : A' \to A \) and \( b : B' \to B \) are any pair of functors, then the pullback defines a module \( A' \leftarrow E(b, a) \to B' \) from \( A' \) to \( B' \).

**Proof.** The cosmological functor

\[
(a, b)^* : A \backslash \text{Fib} (\mathcal{K})_{/B} \to A' \backslash \text{Fib} (\mathcal{K})_{/B'}
\]

of Proposition 7.2.4 preserves discrete objects in these \( \infty \)-cosmoi.

Applying Proposition 7.4.5 to a pair of elements \( a : 1 \to A \) and \( b : 1 \to B \), we see that a module from \( A \) to \( B \) is a two-sided fibration whose fibers \( E(b, a) \) are discrete \( \infty \)-categories. The converse does not generally hold: being discrete as an object of the sliced \( \infty \)-cosmos \( \mathcal{K}_{/A \times B} \) is a stronger condition than merely having discrete fibers. However, when \( \mathcal{K} \) is an \( \infty \)-cosmos of \((\infty,1)\)-categories, Proposition 12.2.3 proves that discreteness in a slice is implied by fiberwise discreteness, essentially because in such \( \infty \)-cosmoi the terminal \( \infty \)-category 1 is a “generator” in a sense explored in §12.2. In anticipation of those results, we prove:

**7.4.6. Lemma.** If \( E \to A \times B \) is a two-sided fibration of quasi-categories whose fibers are Kan complexes, then \( E \) is a module.

**Proof.** By definition, \( E \to A \times B \) defines a discrete object in \( QC\text{at}_{/A \times B} \) if any 1-simplex in \( E^{X} \) that lies over a degenerate 1-simplex in \( (A \times B)^X \) is an isomorphism. As isomorphisms in functor quasi-categories are determined pointwise by Corollary 1.1.21, it suffices to consider the case \( X = 1 \) and now this reduces to the hypothesis that the fibers \( E(b, a) \) over any pair of points \( (a, b) \in A \times B \) are Kan complexes.

The prototypical examples of modules are given by the arrow and comma \( \infty \)-category constructions.

**7.4.7. Proposition (comma \( \infty \)-categories are modules).**
(i) For any ∞-category $A$, the arrow ∞-category $A^2$ defines a module from $A$ to $A$.

(ii) For any cospan $C \xrightarrow{g} A \xleftarrow{f} B$, the comma ∞-category $\text{Hom}_A(f, g)$ defines a module from $C$ to $B$.

As just remarked, the fact that $A^2 \to A \times A$ is discrete is related to but stronger than the fact, proven in Proposition 3.4.10, that the internal mapping space between any pair of elements of $A$ is a discrete ∞-category.

**Proof.** By Proposition 7.4.5, the second statement follows from the first, but it is no harder to prove both statements at once from our suite of established results. Proposition 7.1.6 and Example 7.2.8 prove that arrow and comma spans define two-sided fibrations, so it remains only to verify the discreteness conditions. Discreteness of $A^2 \to A \times A$ in the sliced ∞-cosmos over $A \times A$ and $\text{Hom}_A(f, g) \to C \times B$ in the sliced ∞-cosmos over $C \times B$ are immediate consequences of 2-cell conservativity of Proposition 3.2.5 and Proposition 3.4.6: for the latter, if $\tau$ is any 2-cell with codomain $\text{Hom}_A(f, g)$ so that $p_0 \tau$ and $p_1 \tau$ are invertible, then $\tau$ is itself invertible. \[\square\]

Two special cases of these comma modules, those studied in §3.5, deserve a special name:

**7.4.8. Definition.** To any functor $f : A \to B$ between ∞-categories

(i) the module $\text{Hom}_B(B, f)$ from $A$ to $B$ is right or covariantly represented by $f$, while

(ii) the module $\text{Hom}_B(f, B)$ from $B$ to $A$ is left or contravariantly represented by $f$.

More generally, a module is covariantly or contravariantly represented by $f$ if it is fibered equivalent to the left or right represented modules.

As we saw in §5.7, the Yoneda lemma for two-sided fibrations simplifies when mapping into a module on account of the observation in Lemma 7.4.3(iv) that any map of spans from a two-sided fibration to a module defines a cartesian functor.

**7.4.9. Theorem (Yoneda for modules).** For any generalized elements $a : X \to A$ and $b : X \to B$ and any module $A \xleftarrow{E} \xrightarrow{p} B$, restriction along $(\text{id}_a, \text{id}_b) : X \to \text{Hom}_A(a, A) \times \text{Hom}_B(B, b)$ defines an equivalence of Kan complexes

$$\text{ev}_{(\text{id}_a, \text{id}_b)} : \text{Fun}_{A \times B} \left( \begin{array}{c}
\text{Hom}_A(a, A) \times \text{Hom}_B(B, b) \\
E \\
(\text{id}_1, \text{id}_2)
\end{array} \right) \xrightarrow{\sim} \text{Fun}_{A \times B} \left( \begin{array}{c}
X \\
E \\
(a, b)
\end{array} \right).$$

Similarly for any functors $f : A \to B$ or $g : B \to A$, restriction along $(\text{id}_f, \text{id}_g) : A \to \text{Hom}_B(B, f)$ or $(\text{id}_g, \text{id}_f) : B \to \text{Hom}_A(g, A)$ define equivalences of Kan complexes

$$\text{ev}_{\text{id}_f} : \text{Fun}_{A \times B} \left( \begin{array}{c}
\text{Hom}_B(B, f) \\
E \\
(\text{id}_1, \text{id}_2)
\end{array} \right) \xrightarrow{\sim} \text{Fun}_{A \times B} \left( \begin{array}{c}
A \\
E \\
(id, f)
\end{array} \right).$$

$$\text{ev}_{\text{id}_g} : \text{Fun}_{A \times B} \left( \begin{array}{c}
\text{Hom}_A(g, A) \\
E \\
(\text{id}_1, \text{id}_2)
\end{array} \right) \xrightarrow{\sim} \text{Fun}_{A \times B} \left( \begin{array}{c}
B \\
E \\
(g, id)
\end{array} \right).$$ \[\square\]
We have not yet explained the curious terminology—why we refer to discrete two-sided fibrations as “modules.” This moniker is intended to suggest a deep structural analogy between the calculus of modules and the calculus of the more familiar algebraic structure, a subject to which we now turn.

Exercises.

7.4.i. Exercise. Demonstrate by means of an example that if $A \xleftarrow{q} E \xrightarrow{p} B$ defines a module from $A$ to $B$ then it is not necessarily the case that $p: E \rightarrow B$ is a discrete cartesian fibration or $q: E \rightarrow A$ is a discrete cocartesian fibration.

7.4.ii. Exercise.

(i) Explain why the two-sided fibration $(p_{n-1}, p_0): A^n \rightarrow A \times A$ of Proposition 7.1.6 does not define a module for $n > 2$.

(ii) Conclude that the horizontal composite of modules, as defined in Proposition 7.2.6, is not necessarily a module.

7.4.iii. Exercise. State and prove an analogue of Exercise 7.1.i characterizing modules from $1$ to $B$ and modules from $B$ to $1$, and resolve any apparent conflicts between this statement and Exercise 7.4.i.
The Calculus of Modules

The calculus of modules between $\infty$-categories bears a strong resemblance to the calculus of (bi)modules between unital rings. Here $\infty$-categories take the place of rings, with functors between $\infty$-categories playing the role of ring homomorphisms, which we display vertically in the table below. A module $E$ from $A$ to $B$, like the two-sided fibrations considered in Chapter 7, is an $\infty$-category on which $A$ “acts on the left” and $B$ “acts on the right” and these actions commute; this is analogous to the notation of $A$–$B$ bimodule in ring theory and explains our choice of terminology. A module $A \xleftarrow{q} E \xrightarrow{p} B$ will now be depicted as $A \xrightarrow{E} B$ whenever explicit names for the legs of the constituent span are not needed.

Finally, there is a notion of module map, to be introduced presently, whose boundary in the most general case is a square comprised of two modules and two functors as above. In ring theory, a module map with this boundary is given by an $A'$–$B'$ module homomorphism $E' \rightarrow E(b, a)$, whose codomain is the $A'$–$B'$ bimodule defined by restricting the scalar multiplication in the $A$–$B$ module $E$ along the ring homomorphisms $a$ and $b$. A similar idea is encoded by Definition 8.1.6.

The analogy extends deeper than this: unital rings, ring homomorphisms, bimodules, and module maps define a proarrow equipment, in the sense of Wood [128].¹ Our main result in this chapter is Theorem 8.2.6, which asserts that $\infty$-categories, functors, modules, and module maps in any $\infty$-cosmos define a virtual equipment, in the sense of Cruttwell and Shulman [32].

As a first step, in §8.1 we introduce the double category of two-sided fibrations, which restricts to define a virtual double category of modules. A double category is a sort of 2-dimensional category with objects; two varieties of 1-morphisms, the “horizontal” and the “vertical”; and 2-dimensional cells fitting into “squares” whose boundaries consist of horizontal and vertical 1-morphisms with compatible

¹This can be seen as a special case of the prototypical equipment comprised of $\mathcal{V}$-categories, $\mathcal{V}$-functors, $\mathcal{V}$-modules, and $\mathcal{V}$-natural transformations between them, for any closed symmetric monoidal category $\mathcal{V}$. The equipment for rings is obtained from the case where $\mathcal{V}$ is the category of abelian groups by restricting to abelian group enriched categories with a single object.
domains and codomains. A motivating example from abstract algebra is the double category of modules: objects are rings, vertical morphisms are ring homomorphisms, horizontal morphisms are bimodules, and whose squares are bimodule homomorphisms. Vertical composition is by composing homomorphisms, a strictly associative and unital operation, while horizontal composition is by tensor product of modules, which is associative and unital up to coherent natural isomorphism. In the literature, this sort of structure is sometimes called a pseudo double category — morphisms and squares compose strictly in the “vertical” direction but only up to isomorphism in the “horizontal” direction — but we refer to this simply as a “double category” as it is the only variety considered here.

Our aim in §8.1 is to describe a similar structure whose objects and vertical morphisms are the $\infty$-categories and functors in any fixed $\infty$-cosmos, whose horizontal morphisms are modules, and whose squares are module maps. If the horizontal morphisms are replaced by the larger class of two-sided fibrations, this does define a double category with the horizontal composition operation defined by Proposition 7.2.6. However, on account of Exercise 7.4.ii, the horizontal composition of two-sided fibrations does not preserve the class of modules: the arrow $\infty$-category $A^2$ defines a module from $A$ to $A$ whose horizontal composite with itself is equivalent to the two-sided fibration $p_2 : A \to A \times A$ of Proposition 7.1.6, which is not discrete in the sliced $\infty$-cosmos over $A \times A$. To define a genuine “tensor product for modules” operation would require a two-stage construction: first forming the pullback that defines a composite two-sided fibration as in Proposition 7.2.6, and then reflecting this into a two-sided discrete fibration by means of some sort of “homotopy coinverter” construction. As colimits that are not within the purview of the axioms of an $\infty$-cosmos, this presents somewhat of an obstacle.

Rather than leave the comfort of our axiomatic framework in pursuit of a double category of modules, we instead describe the structure that naturally arises within the axiomatization, which turns out to be familiar to category theorists and robust enough for our desired applications. We first demonstrate that $\infty$-categories, functors, modules, and module maps assemble into a virtual double category, a weaker structure than a double category in which cells are permitted to have a multi horizontal source, as a “virtual” replacement for horizontal composition of modules. Virtual double categories relate to double categories as multicategories relate to monoidal categories; indeed virtual double categories are the “generalized multicategories” defined relative to the free category monad on directed graphs [32].

A virtual equipment is a virtual double category satisfying two additional axioms. One of these provides a “restriction of scalars” operation, allowing a horizontal morphism $A \to B$ to be pulled back along a pair of vertical morphisms $a' : A' \to A$ and $b' : B' \to B$. The other condition requires each object to have a horizontal “unit” morphism, satisfying a suitable universal property that serves as a substitute, in the absence of a composition operation, for the unital composition rules. Once the definition of a virtual equipment is given in §8.2, these axioms are very easily checked. The final two sections are devoted to exploring the consequences of this structure, which will be put to full use in Chapter 9, which develops the formal category theory of $\infty$-categories by introducing Kan extensions in the virtual equipment of modules. In §8.3, we explain how certain horizontal composites of modules can be recognized in the virtual equipment, even if the general construction of the tensor product of an arbitrary composable pair of modules is not known. The final §8.4 collects together many special properties of the modules $A_{\Hom_B(B,f)} \to B$ and $B_{\Hom_B(f,B)} \to A$ represented by a functor $f : A \to B$ of $\infty$-categories, revisiting some of the properties first established in §3.5.
8.1. The Double Category of Two-Sided Fibrations

Our first task is to define the 2-dimensional morphisms in the double categories that we will introduce. We build up to the generation notion in Definition 8.1.6 in stages.

8.1.1. Definition. Let \( A \xleftarrow{q} E \xrightarrow{p} B \) and \( A \xleftarrow{s} F \xrightarrow{r} B \) be two-sided isofibrations. A fibered map of two-sided isofibrations from \( A \xleftarrow{q} E \xrightarrow{p} B \) to \( A \xleftarrow{s} F \xrightarrow{r} B \) is a fibered isomorphism class of strictly commuting functors

\[
\begin{array}{ccc}
A & \xleftarrow{q} & E \\
\downarrow{s} & & \downarrow{p} \\
F & \xleftarrow{q} & B
\end{array}
\]

where two such functors \( h \) and \( h' \) are considered equivalent if there exists a natural isomorphism \( \alpha : h \cong h' \) so that \( r\alpha = \text{id}_p \) and \( s\alpha = \text{id}_q \).

8.1.2. Definition. Let \( A \xleftarrow{q} E \xrightarrow{p} B \) and \( A \xleftarrow{s} F \xrightarrow{r} B \) be two-sided fibrations. A fibered map of two-sided fibrations from \( A \xleftarrow{q} E \xrightarrow{p} B \) to \( A \xleftarrow{s} F \xrightarrow{r} B \) is a fibered map of two-sided isofibrations in which any and hence every representing map

\[
\begin{array}{ccc}
A & \xleftarrow{q} & E \\
\downarrow{s} & & \downarrow{p} \\
F & \xleftarrow{q} & B
\end{array}
\]

defines a cartesian functor of two-sided fibrations defined in Proposition 7.1.7.

8.1.3. Definition. Let \( A \xleftarrow{q} E \xrightarrow{p} B \) and \( A \xleftarrow{s} F \xrightarrow{r} B \) be modules. A fibered map of modules from \( E \) to \( F \) is just a fibered map of two-sided isofibrations from \( A \xleftarrow{q} E \xrightarrow{p} B \) to \( A \xleftarrow{s} F \xrightarrow{r} B \), that is a fibered isomorphism class of strictly commuting functors

\[
\begin{array}{ccc}
A & \xleftarrow{q} & E \\
\downarrow{s} & & \downarrow{p} \\
F & \xleftarrow{q} & B
\end{array}
\]

8.1.4. Observation (the 1-categories of spans and fibered maps). The 1-category of two-sided isofibrations from \( A \) to \( B \) in an \( \infty \)-cosmos \( K \) may be obtained as a quotient of the quasi-categorically enriched category \( K_{/A \times B} \), or of its homotopy 2-category \( h(K_{/A \times B}) \), or of the slice homotopy 2-category \( h(K_{/A \times B}) \): it is the 1-category with the same set of objects and in which the morphisms are isomorphism classes of 0-arrows.

Similarly, the 1-category of two-sided fibrations from \( A \) to \( B \) and maps of two-sided fibrations may be obtained as a quotient of the quasi-categorically enriched category \( A \downarrow \text{Fib}(K)_{/B} \), or of its homotopy 2-category \( h(A \downarrow \text{Fib}(K)_{/B}) \): it is the 1-category with the same set of objects and in which the morphisms are isomorphism classes of 0-arrows.
By Lemma 7.4.3, the 1-category of modules from $A$ to $B$ and modules maps is a full subcategory of either of the two 1-categories just considered, or alternatively may be regarded as a quotient of the Kan complex enriched category $A\backslash \text{Mod}(\mathcal{K})/B$, or of its homotopy 2-category $\mathcal{h}(A\backslash \text{Mod}(\mathcal{K})/B)$ in the same manner.

The 1-categories of Observation 8.1.4 are of interest because they precisely capture the correct notion of equivalence between two-sided isofibrations, two-sided fibrations, or modules first introduced in Definition 3.2.7.

8.1.5. LEMMA. In an $\infty$-cosmos $\mathcal{K}$:

(i) A pair of two-sided isofibrations are equivalent in $\mathcal{K}_{A\times B}$ if and only if they are isomorphic in the 1-category of spans from $A$ to $B$.

(ii) A pair of two-sided fibrations are equivalent in $A\backslash \text{Fib}(\mathcal{K})/B$ if and only if they are isomorphic in the 1-category of two-sided fibrations from $A$ to $B$.

(iii) A pair of modules are equivalent over $A$ times $B$ if and only if they are isomorphic in the 1-category of modules from $A$ to $B$. □

Each of the definitions just presented admits a common generalization, which defines the 2-dimensional maps inhabiting squares.

8.1.6. DEFINITION (maps in squares). A map of modules or map of two-sided fibrations or map of two-sided isofibrations from $A' \leftarrow q' \rightarrow E' \rightarrow B'$ to $A \leftarrow q \rightarrow E \rightarrow B$ over $a: A' \rightarrow A$ and $b: B' \rightarrow B$, depicted as

$$
\begin{array}{ccc}
A' & \xrightarrow{E'} & B' \\
\downarrow a & & \downarrow b \\
A & \xrightarrow{E} & B
\end{array}
$$

is a fibered isomorphism class of strictly commuting functors $h$ as displayed below-right,

$$
\begin{array}{ccc}
A' & \xleftarrow{q'} & E' & \xrightarrow{p'} & B' \\
\downarrow a & & \downarrow h & & \downarrow b \\
A & \xleftarrow{q} & E & \xrightarrow{p} & B
\end{array}
$$

which in the case of two-sided fibrations must preserve the cartesian and cocartesian transformations, where two such functors $h$ and $h'$ are considered equivalent if there exists a natural isomorphism $\alpha: h \cong h'$ so that $q\alpha = \text{id}_{q'q}$ and $p\alpha = \text{id}_{pp'}$.

8.1.7. OBSERVATION. In the case of modules or two-sided isofibrations, the functor space $\text{Fun}_{A\times B}(E', E)$ of maps from $E'$ to $E$ over $A \times B$ is defined by the pullback

$$
\begin{array}{ccc}
\text{Fun}_{A\times B}(E', E) & \longrightarrow & \text{Fun}(E', E) \\
\downarrow & & \downarrow \cong{(q,p)} \\
\mathbb{I} & \xrightarrow{(aq', fp')} & \text{Fun}(E', A \times B)
\end{array}
$$

In the case of two-sided fibrations, the functor space is taken to be the full sub quasi-category $\text{Fun}_{A\times B}^{\text{cart}}(E', E) \subset \text{Fun}_{A\times B}(E', E)$.
of all \(n\)-simplices whose vertices define cartesian functors between two-sided fibrations. As in Observation 8.1.4, module maps are defined to be isomorphism classes of objects in this functor space.

We now introduce the double categories of isofibrations and of two-sided fibrations. These structures can be viewed either as a collection of data present in the homotopy 2-category \(\mathcal{K}\) of an \(\infty\)-cosmos or as a quotient of quasi-categorically enriched structures described in Exercise 8.1.1. In some sense the latter point of view is more natural, as it avoids the use of isomorphism classes in the definition of maps of modules, but the 2-categorical approach is more familiar and provides a convenient setting within which to develop the formal category theory of \(\infty\)-categories, as we shall discover.

8.1.8. Proposition (the double category of two-sided (iso)fibrations). The homotopy 2-category of an \(\infty\)-cosmos \(\mathcal{K}\) supports a (non-unital) double category of two-sided isofibrations whose:

- objects are \(\infty\)-categories,
- vertical arrows are functors,
- horizontal arrows \(A \xrightarrow{E} B\) are two-sided isofibrations \(A \leftrightarrow E \rightarrow B\), and
- cells with boundary

\[
\begin{array}{ccc}
A' & \xrightarrow{E'} & B' \\
\downarrow^a & \Downarrow & \downarrow^b \\
A & \xrightarrow{E} B
\end{array}
\]

are maps of two-sided isofibrations over \(a \times b\), or equivalently, are isomorphism classes of objects in the quasi-category \(Fun_{\text{ax}}(E', E)\).

The (non-unital) double category of two-sided fibrations is the sub double category that has the same objects and vertical arrows but whose:

- horizontal arrows \(A \xrightarrow{E} B\) are two-sided fibrations \(A \leftrightarrow E \rightarrow B\) and
- cells with boundary

\[
\begin{array}{ccc}
A' & \xrightarrow{E'} & B' \\
\downarrow^a & \Downarrow & \downarrow^b \\
A & \xrightarrow{E} B
\end{array}
\]

are maps of two-sided fibrations over \(a \times b\), or equivalently, are isomorphism classes of objects in the quasi-category \(Fun_{\text{car}}(E', E)\).

Proof. Vertical composition of arrows and cells is by composition in \(\mathcal{K}\). The composition of horizontal arrows is defined in Proposition 7.2.6, while the horizontal composition of cells is defined in Exercise 7.2.1. By simplicial functoriality of pullback and composition in \(\mathcal{K}\), both constructions are associative up to canonical natural isomorphism.

The double categories just introduced do not contain horizontal unit arrows. For technical reasons, we find it most convenient to leave them out:

8.1.9. Remark (why we left out the horizontal identity). The unit for the span composition operation defined in Proposition 7.2.6 is the identity span, which is not typically a two-sided isofibration. Rather than formally adjoin horizontal identities to the “double categories” of Proposition 8.1.8, we find it less
confusing to leave them out because when we restrict to the structure of greatest interest—the virtual equipment of modules—we will see that the arrow $\infty$-category plays the role of the horizontal unit for composition in a sense to be described in Proposition 8.2.4, even though it does not define a horizontal composition unit in the conventional sense.

By Exercise 7.4.ii, modules do not form double category under span composition, which leads us to search for another categorical structure to axiomatize their behavior. A virtual double category is a multicategorical analogue of a double category appropriate for settings when horizontal composition and units may or may not be defined. This notion has been studied by Burroni [24] and Leinster [73] under various names, though we adopt the terminology and notation of Cruttwell and Shulman [32].

8.1.10. Definition (virtual double category). A virtual double category consists of

- a category of objects and vertical arrows
- for any pair of objects $A$, $B$, a class of horizontal arrows $A \to B$
- cells, with boundary depicted as follows

\[
\begin{array}{cccccc}
A_0 & \overset{E_1}{\longrightarrow} & A_1 & \overset{E_2}{\longrightarrow} & \cdots & \overset{E_n}{\longrightarrow} & A_n \\
\downarrow f & & \downarrow \uparrow & & \downarrow \downarrow g & \\
B_0 & \underset{F}{\longrightarrow} & B_1 & \cdots & \cdots & \cdots & B_n
\end{array}
\]

(8.1.11)

including, in the case $A_0 = A_n$, those whose horizontal source has length zero
- a composite cell as below-right, for any configuration as below-left

\[
\begin{array}{cccccc}
A_0 & \overset{E_{11}, \ldots, E_{1k_1}}{\longrightarrow} & A_1 & \overset{E_{21}, \ldots, E_{2k_2}}{\longrightarrow} & \cdots & \overset{E_{n1}, \ldots, E_{nk_n}}{\longrightarrow} & A_n \\
\downarrow f_0 & \downarrow f_1 & \downarrow f_2 & \cdots & \downarrow f_n & & \\
B_0 & \overset{E_0}{\longrightarrow} & B_1 & \cdots & \cdots & \cdots & B_n
\end{array}
\quad \overset{hf_n}{\longrightarrow} \quad \begin{array}{cccccc}
A_0 & \overset{E_{11}, \ldots, E_{nk_n-1}, E_{nk_n}}{\longrightarrow} & A_n \\
\downarrow g_0 & \downarrow g_1 & \downarrow g_2 & \cdots & \downarrow g_n & \downarrow h & \\
C_0 & \overset{G}{\longrightarrow} & C_1 & \cdots & \cdots & \cdots & C_n
\end{array}
\]

(8.1.12)

• an identity cell for every horizontal arrow

\[
\begin{array}{ccc}
A & \overset{E}{\longrightarrow} & B \\
\downarrow \id_E & & \downarrow \id_E \\
A & \underset{E}{\longrightarrow} & B
\end{array}
\]

so that composition of cells is associative and unital in the usual multi-categorical sense.

8.1.13. Lemma. There exists a virtual double category of isofibrations and a virtual double category of two-sided fibrations whose:

- objects are $\infty$-categories,
- vertical arrows are functors,
- horizontal arrows are two-sided isofibrations or two-sided fibrations as appropriate, and
- **n-ary cells** (8.1.11) are maps of two-sided isofibrations or maps of two-sided fibrations as appropriate over \( f \times g \)

\[
\begin{array}{ccc}
A_0 & \xrightarrow{E_1 \times \cdots \times E_n} & A_n \\
\downarrow f & & \downarrow g \\
B_0 & \xrightarrow{F} & B_n
\end{array} \quad \iff \quad \begin{array}{ccc}
A_0 & \xleftarrow{A_1} & A_{n-1} \\
\downarrow f & & \downarrow g \\
B_0 & \xleftarrow{F} & B_n
\end{array}
\]

whose single vertical source is the \((n-1)\)-fold span composite of the sequence of spans comprising the vertical source in (8.1.11).

**Proof.** The required composition laws can be defined by embedding the virtual double categories into the double categories of Proposition 8.1.8. For instance, the composition of a configuration as on the left of (8.1.12) can be defined by horizontally composing the \( k \) top cells in the double category of isofibrations, and then vertically composing the result with the bottom cell. The result will be a \( k_1 + \cdots + k_n \)-ary cell in the virtual double category of the correct form.

It remains only to define the nullary cells\(^3\) which have an empty sequence as their vertical domain

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow g & \downarrow & \downarrow \rho \\
A & \xleftarrow{h} & C
\end{array} \quad \iff \quad \begin{array}{ccc}
A & \xrightarrow{f} & B \xleftarrow{h} & C \\
\downarrow g & \downarrow & \downarrow \rho & \downarrow \sigma \\
A & \xleftrightarrow{s} & B & \xleftrightarrow{r}
\end{array}
\]

which we interpret as a 0-fold pullback, this being the identity span from \( A \) to \( A \). So the nullary cells displayed above-left are fibered isomorphism classes of maps above-right where \( h \) and \( h' \) lie in the same equivalence class if there exists a natural isomorphism \( \alpha : h \cong h' \) so that \( s \alpha = \text{id}_f \) and \( r \alpha = \text{id}_g \).

8.1.15. **Remark.** For instance, the map

\[
\begin{array}{ccc}
A & \xleftarrow{q_1} & A \xrightarrow{\Delta} A \\
\downarrow q_0 & \downarrow & \downarrow q_0 \\
A & \xleftrightarrow{A} & A
\end{array}
\]

defines a nullary morphism with codomain \( A \xrightarrow{A} A \) in the virtual double category of two-sided isofibrations. Note, however, that despite the fact that \( \Delta : A \Rightarrow A \xrightarrow{\Delta} A \) defines an equivalence in the ambient \( \infty \)-cosmos, this cell does not define an isomorphism in the virtual double category of any kind. This nullary morphism will endow \( A \xrightarrow{A} A \) with the structure of a unit in a sense suitable to virtual double categories; see Exercise 8.2.iii. It is for this sort of reason that we left out the identity horizontal arrows in Proposition 8.1.8.

\(^3\)Note the use of the symbol \( A \xrightarrow{A} A \) to denote the nullary source of a nullary cell, adopted so such cells fit naturally into composite diagrams of cells in a virtual double category.
Our main example of interest is a full sub virtual double category defined by restricting the class of horizontal arrows and taking all cells between them. Since the only operations given in the structure of a virtual double category are vertical sources and targets, vertical identities, and vertical composition, it is clear that this substructure is closed under all of these operations, and thus inherits the structure of a virtual double category:

8.1.16. Corollary. For any ∞-cosmos \( \mathcal{K} \), there is a virtual double category of modules \( \text{Mod}(\mathcal{K}) \) defined as a full subcategory of either the virtual double categories of isofibrations or the virtual double category of two-sided fibrations whose

- objects are ∞-categories,
- vertical arrows are functors,
- horizontal arrows \( A \xrightarrow{E} B \) are modules \( E \) from \( A \) to \( B \),
- \( n \)-ary cells are fibered isomorphism classes of maps of two-sided isofibrations over \( f \times g \):

\[
\begin{array}{ccc}
  A_0 & \xrightarrow{E_1} & A_1 \\
  f \downarrow & & \downarrow \delta \\
  B_0 & \xrightarrow{\delta} & B_1
\end{array}
\quad
\begin{array}{ccc}
  A_0 & \xrightarrow{E_1 \times \cdots \times E_n} & A_n \\
  f \downarrow & & \downarrow \delta \\
  B_0 & \xrightarrow{\delta} & B_n
\end{array}
\]

The \( n \)-ary module maps of (8.1.17) can be thought of as special cases of the \( n \)-ary cells of Lemma 8.1.13 where \( E_1, \ldots, E_n, F \) are all required to be modules: the single horizontal source in the diagram (8.1.14) is the two-sided fibration defined by the \((n-1)\)-fold pullback of the sequence of modules comprising the horizontal source in the left-hand diagram. We refer to the finite sequence of modules occurring as the horizontal domain of an \( n \)-ary module map as a compatible sequence of modules, which just means that their horizontal sources and targets are compatible in the evident way.

A hint at the relevance of this notion of \( n \)-ary module map is given by the following special case.

8.1.18. Lemma. There is a bijection between \( n \)-ary module maps whose codomain module \( B \xrightarrow{\text{Hom}_D(h,k)} C \) is a comma as displayed below-left and natural transformations in the homotopy 2-category whose boundary is displayed above-right.

\[
\begin{array}{ccc}
  A_0 & \xrightarrow{E_1} & A_1 \\
  f \downarrow & & \downarrow \delta \\
  B & \xrightarrow{\delta} & C
\end{array}
\quad
\begin{array}{ccc}
  A_0 & \xrightarrow{E_1 \times \cdots \times E_n} & A_n \\
  f \downarrow & & \downarrow \delta \\
  B & \xrightarrow{\delta} & C
\end{array}
\]

Proof. Combine Definition 8.1.6 with Proposition 3.4.7. \( \square \)

For any pair of objects \( A \) and \( B \) in the virtual double category of modules, there is a vertical 1-category of modules from \( A \) to \( B \) and module maps over a pair of identity functors, which coincides with the 1-category of modules from \( A \) to \( B \) introduced in Observation 8.1.4.
8.1.19. **Lemma.** A parallel pair of modules $A \overset{E}{\to} B$ and $A \overset{F}{\to} B$ are isomorphic as objects of vertical 1-category of modules in the virtual double category of modules if and only if $E \cong_{A \times B} F$, i.e., if the modules $E$ and $F$ are equivalent as spans from $A$ to $B$.

**Proof.** This is a restatement of Lemma 8.1.5(iii). □

For consistency with the rest of the text, we write $E \cong F$ or $E \cong_{A \times B} F$ whenever the modules $A \overset{E}{\to} B$ and $A \overset{F}{\to} B$ are isomorphic as objects of the vertical 1-category of modules from $A$ to $B$. For instance, Proposition 4.1.1 proves that a functor $f: B \to A$ is left adjoint to a functor $u: A \to B$ if and only if $\text{Hom}_A(f, A) \cong \text{Hom}_B(B, u)$ over $A \times B$, that is, if and only if the modules $B \overset{\text{Hom}_A(f, A)}{\to} A$ and $A \overset{\text{Hom}_B(B, u)}{\to} B$ are isomorphic as objects of the vertical 1-category of modules from $A$ to $B$. We will have more to say about this sort of statement in §8.4.

**Exercises.**

8.1.i. **Exercise.** By Exercise 6.1.iii, for any $\infty$-cosmos $\mathbf{K}$, there is an $\infty$-cosmos $\mathbf{K}^\otimes$ whose objects are two-sided isofibrations between an arbitrary pair of $\infty$-categories, these being exactly the “fibrant diagrams” indexed by the span, considered as an inverse category. Use this $\infty$-cosmos together with the endpoint-evaluation functors $\mathbf{K}^\otimes \to \mathbf{K}$ to give a second description of the double category of two-sided isofibrations as as quotient of a non-unital internal category defined at the level of $\infty$-cosmoi, cosmological functors, and simplicial natural isomorphisms.³

8.1.ii. **Exercise.** Prove that any double category defines a virtual double category.⁴

8.1.iii. **Exercise.** Use the three statements of Theorem 7.4.9 to describe three bijections between cells with various boundary shapes in the virtual double category of modules.

### 8.2. The Virtual Equipment of Modules

The virtual double category of modules $\text{Mod}(\mathbf{K})$ in an $\infty$-cosmos $\mathbf{K}$ has two special properties that characterize what Cruttwell and Shulman term a *virtual equipment*. Before stating the definition, we explore each of these in turn.

8.2.1. **Proposition (restriction).** Any diagram in $\text{Mod}(\mathbf{K})$ as below-left can be completed to a cartesian cell as below-right

\[
\begin{array}{ccc}
A' & \overset{E}{\to} & B' \\
\downarrow_{a} & & \downarrow_{b} \\
A & \to & B
\end{array}
\quad \sim \quad
\begin{array}{ccc}
A' & \overset{E(b,a)}{\to} & B' \\
\downarrow_{a} & \Downarrow_{\rho} & \downarrow_{b} \\
A & \overset{E}{\to} & B
\end{array}
\]

³We consider it to be an open problem whether it is useful to take a “double quasi-categorical” on the non-unital double category of two-sided fibrations or the virtual double category of modules.

⁴If the double category lacks horizontal identity morphisms, the corresponding virtual double category may lack nullary morphisms — unless these can be defined in some other way as we did in the proof of Lemma 8.1.13. Note that if we added identity spans to our double category of two-sided isofibrations, then the corresponding virtual double category would be the correct one, which contains the virtual double category of modules. See Remark 8.1.15 however.
characterized by the universal property that any cell as displayed below-left factors uniquely through $\rho$ as below-right:

\[
\begin{array}{c}
X_0 \xrightarrow{E_1} X_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} X_n \\
\downarrow{af} \Downarrow{\mathcal{E}} \\
A \xrightarrow{E} B
\end{array}
\quad =
\begin{array}{c}
X_0 \xrightarrow{E_1} X_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} X_n \\
\downarrow{f} \Downarrow{\exists!} \downarrow{bg} \\
A' \xrightarrow{E(\mathcal{B},\mathcal{A})} B'
\end{array}
\]

**Proof.** The horizontal source of the cartesian cell is defined by restricting the module $A \xrightarrow{E} B$ along the functors $a$ and $b$:

\[
\begin{array}{c}
E(\mathcal{B},\mathcal{A}) \xrightarrow{\rho} E \\
\downarrow{\mathcal{A}} \downarrow{\mathcal{B}(a,b)} \\
A' \times B' \xrightarrow{(a,b)} A \times B
\end{array}
\]  

(8.2.2)

By Proposition 7.4.5, this left-hand isofibration defines a module from $A'$ to $B'$, while by Definition 8.1.6 the top horizontal functor represents a module map inhabiting the desired square. By Observation 8.1.7, the simplicial pullback in $\mathcal{K}$ induces an equivalence\(^4\) of functor spaces:

\[
\text{Fun}_{f \times g}(E_1 \times \cdots \times E_n, E) \xrightarrow{\rho^\ast} \text{Fun}_{af \times bg}(E_1 \times \cdots \times E_n, E)
\]

which descends to a bijection on isomorphism classes of objects. This defines the unique factorization of cells as displayed above left through the cartesian restriction cell $\rho$. \hfill \square

We refer to the module $A' \xrightarrow{E(\mathcal{B},\mathcal{A})} B'$ as the restriction of $A \xrightarrow{E} B$ along the functors $a$ and $b$, because the pullback (8.2.2) is analogous to the restriction of scalars of a bimodule along a pair of ring homomorphisms.

**8.2.3. Example.** The module $C \xrightarrow{\text{Hom}_{A}(f,g)} B$ is the restriction of the module encoded by the arrow $\infty$-category $A \xleftarrow{p_1} A^2 \xrightarrow{p_0} A$ along $g : C \to A$ and $f : B \to A$. To make this restriction relationship more transparent, we typically write $A \xrightarrow{\text{Hom}_{A}(f,g)} A$ when regarding the arrow $\infty$-category as a module.

\[
\begin{array}{c}
C \xrightarrow{g} B \\
\downarrow{\mathcal{A}} \Downarrow{\mathcal{B}(a,b)} \\
A \xrightarrow{\text{Hom}_{A}(f,g)} A
\end{array}
\]

\(^4\)If the pullbacks are defined strictly, then in fact pullback induces an isomorphism of functor spaces, but even if $E(\mathcal{B},\mathcal{A})$ is replaced by an equivalent module, the functor spaces are still equivalent, which enough to induce a bijection on isomorphism classes of objects.
Since the common notation for “homs” places the contravariant variable on the left and the covariant variable on the right, we have adopted a similar notation convention for restrictions in Proposition 8.2.1.

8.2.4. PROPOSITION (units). Any object $A$ in $\mathbf{Mod}(\mathcal{K})$ is equipped with a nullary cocartesian cell as displayed below:

$$
\begin{array}{c}
A \\ \downarrow t \\ A \\
\end{array}
\quad
\begin{array}{c}
A \\
\downarrow t \\
A
\end{array}
$$

characterized by the universal property that any cell in $\mathbf{Mod}(\mathcal{K})$ whose horizontal source includes the object $A$ factors uniquely through $t$ as below-right:

$$
\begin{array}{c}
E_1 \to \cdots \to E_n \to A \\
\downarrow f \\
B
\end{array}
\quad
\begin{array}{c}
X \\
\downarrow E_1 \\
E_n
\end{array}
\quad
\begin{array}{c}
F_1 \to \cdots \to F_m \\
\downarrow f \\
C
\end{array}
\quad
\begin{array}{c}
Y \\
\downarrow \text{id}
\end{array}
$$

PROOF. The nullary cell is represented by the map of spans

$$
\begin{array}{c}
A \\
\downarrow \text{id}
\end{array}
\quad
\begin{array}{c}
A \\
\downarrow \text{id}
\end{array}
$$

induced by the identity 2-cell at the identity 1-cell at $A$; recall from Example 8.2.3 that we write $A \Rightarrow A$ for the module encoded by the arrow $\infty$-category construction to help us recognize its restrictions.

In the case where both of the sequences $E_i$ and $F_i$ are empty, the one-sided version of the Yoneda lemma for modules given by Theorem 7.4.9 tells us that restriction along the this map induces an equivalence of functor spaces

$$
\text{Fun}_{A \times A}(\text{Hom}_A, G(f)) \cong \text{Fun}_{A \times A}(A, G(g, f)).
$$

Taking isomorphism classes of objects gives the bijection of the statement.

In the case where one or both of the sequences are non-empty, we may form their horizontal composite two-sided fibrations and then form either the horizontal composite $E \times A$ or the
horizontal composite $\text{Hom}_A \times F$ of the composable triple below:

$$
\begin{array}{c}
E \times \text{Hom}_A \times F \\
\downarrow \text{Hom}_A \downarrow \\
\text{Hom}_A(A, p) \downarrow \\
\downarrow \text{Hom}_A \downarrow \\
E \downarrow q \\
\downarrow p \\
A \downarrow p_1 \\
\downarrow p_0 \\
F \downarrow r \\
\downarrow s \\
\downarrow X \times A \\
\downarrow A \\
\downarrow A \times Y \\
\downarrow A \\
\downarrow \text{Hom}_A(s, A) \\
\downarrow \text{Hom}_A(s, A) \\
\downarrow (q, p) \\
\downarrow (q, p_0) \\
\downarrow (s, r) \\
\downarrow (p_1, r) \\
\downarrow \text{Fun}_{X \times Y}(E \times \text{Hom}_A \times F, G(g, f)) \\
\end{array}
$$

In the former case, this constructs the two-sided fibration $(q p_1, p_0) : \text{Hom}_A(A, p) \to X \times A$, and in the latter case this constructs the two-sided fibration $(p_1, r p_0) : \text{Hom}_A(s, A) \to A \times Y$. By Theorem 7.1.4, these two-sided fibrations give rise to fibered adjunctions:

$$
\text{Fun}_{X \times Y}(E \times \text{Hom}_A \times F, G(g, f)) \to \text{Fun}_{X \times Y}(E \times F, G(g, f)),
$$

and once again taking isomorphism classes of objects gives the bijection of the statement. □

Propositions 8.2.1 and 8.2.4 imply that the virtual double category of modules is a virtual equipment in the sense introduced by Cruttwell and Shulman [32, §7].

8.2.5. DEFINITION. A virtual equipment is a virtual double category so that

(i) For any horizontal arrow $A \xrightarrow{E} B$ and pair of vertical arrows $a : A' \to A$ and $b : B' \to B$, there exists a horizontal arrow $B' \xrightarrow{E(b, a)} A'$ and unary cartesian cell $\rho$ satisfying the universal property of Proposition 8.2.1.
(ii) Every object $A$ admits a unit horizontal arrow $A \xrightarrow{\text{Hom}_A \Delta} A$ equipped with a nullary cocartesian cell $t$ satisfying the universal property of Proposition 8.2.4.

Thus, Propositions 8.2.1 and 8.2.4 combine to prove:

8.2.6. **Theorem.** The virtual double category $\mathbf{Mod}(\mathcal{K})$ of modules in an $\infty$-cosmos $\mathcal{K}$ is a virtual equipment. □

By abstract nonsense, the relatively simple axioms (i) and (ii) established in Theorem 8.2.6 establish a robust “calculus of modules.” In an effort to familiarize the reader with this little-known categorical structure and expedite the proofs of the formal category theory of $\infty$-categories in Chapter 9, we devote the remainder of this chapter to proving a plethora of results that actually follow formally from this axiomatization: namely, Lemmas 8.3.10 and 8.3.15, Proposition 8.4.1, Theorem 8.4.4, Corollary 8.4.6, Proposition 8.4.7, Corollary 8.4.8, Corollary 8.4.9, and the bijection of Proposition 8.4.11 between unary cells in the virtual equipment of modules.⁶ One additional result is left as Exercise 8.4.v for the reader.

8.2.7. **Notation.** We adopt the following notational conventions to streamline certain virtual equipment diagrams.

- We adopt the convention that an unlabeled unary cell whose vertical boundaries are identities and whose horizontal sources and targets is an identity cell.

\[
\begin{array}{c}
A \xrightarrow{E} B \\
\| \quad \| \\
A \xrightarrow{E} B
\end{array} =
\begin{array}{c}
A \xrightarrow{E} B \\
\| \quad \| \\
A \xrightarrow{E} B
\end{array}
\]

- Cells whose vertical boundary functors are identities and therefore whose source and target spans lie between the same pair of $\infty$-categories

\[
\mu : E_1 \times \cdots \times E_n \Rightarrow E :=
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} A_n \\
\| \quad \| \\
A_0 \xrightarrow{E} A_n
\end{array}
\]

may be displayed in line using the notation $\mu : E_1 \times \cdots \times E_n \Rightarrow E$, an expression which implicitly asserts that the modules appearing in the domain define a compatible sequence, with the symbol “$\times$” meant to suggest the pullback appearing as the horizontal domain of (8.1.11) rather than a product. In the virtual equipment of modules, cells of the form $\mu : E_1 \times \cdots \times E_n \Rightarrow E$ correspond to fibered maps, in the sense introduced in Definitions 8.1.1–8.1.3.

**Exercises.**

8.2.i. **Exercise.** Given functors $E \xrightarrow{k} C \xrightarrow{g} A \xleftarrow{f} B \xleftarrow{h} D$, compute the restriction of the module $C \xrightarrow{\text{Hom}_A(f,g)} B$ along the functors $k$ and $h$.

⁶Here we observe that the composites references in many of these statements are “strong,” a notion that has no meaning in a generic virtual equipment.
8.2.ii. Exercise. Prove that unital rings, ring homomorphisms, bimodules, and bimodule maps also define a virtual equipment.

8.2.iii. Exercise. Prove that the virtual double category of two-sided isofibrations forms a virtual equipment with the units cells of Remark 8.1.15.

8.3. Composition of Modules

In a virtual equipment, there is no assumption that a generic pair \( A \xrightarrow{E} B \) and \( B \xrightarrow{F} C \) of horizontal morphisms admits a composite but there is a mechanism by which a particular horizontal composite \( A \xrightarrow{G} C \) that happens to exist can be recognized. When \( G \) is the horizontal composite of \( E \) and \( F \), we write \( E \otimes F \simeq G \) or \( \mu: E \otimes F \simeq G \) to reinforce the intuition provided by the analogy with bimodules.

In the virtual equipment of modules, there are two possible meanings we can ascribe to a “horizontal composite” of modules. In the first of these appears in Definition 8.3.1, a composition relation \( \mu: E \otimes F \simeq G \) is witnessed by a module map \( E \times F \Rightarrow G \), in the notation of 8.2.7, that defines a cocartesian cell in a sense analogous to the universal property stated in Proposition 8.2.4. This definition of composition can be given in any virtual double category and is well-behaved in any virtual equipment, such as the virtual equipment of modules. Composites of \( n \)-ary sequences of composable modules are defined analogously.

In the virtual equipment of modules, all of our formally-defined composites will satisfy a stronger universal property expressed at the level of the \( \infty \)-cosmos. Recall that a fibered map \( \mu: E \times F \Rightarrow G \) between modules \( A \xrightarrow{E} B \xleftarrow{F} C \) corresponds to a fibered isomorphism class of maps \( \mu^*: E \times_B F \Rightarrow G \) of spans over \( A \times C \). Part of what it means to say that \( \mu \) witnesses a strong composite in Definition 8.3.5 is the requirement that its representing functor induces an equivalence of Kan complexes \( - \circ \mu^*: \text{Fun}_{A \times C}(G,H) \Rightarrow \text{Fun}_{A \times C}(E \times_B F,H) \) for all modules \( A \xrightarrow{H} C \). When this is the case, the module \( G \) may be understood as the “reflection” of the two-sided isofibration \( E \times_B F \) into the subcategory of modules; note however that \( G \) and \( E \times_B F \) are not necessarily equivalent over \( A \times C \). A special case of Theorem 7.3.2, reappearing as Proposition 8.3.11 below, is one instance of a strong composite.

As this terminology suggests, strong composites are necessarily composites. Since the weaker universal property of being a composite characterizes the composite module up to fibered equivalence, if we are working in an \( \infty \)-cosmos where strong composites are guaranteed to exist, then the 2-categorical universal property we introduce now suffices to detect them.\(^7\)

8.3.1. Definition. A compatible sequence of modules

\[
A \xrightarrow{E_1} A_1, A_1 \xrightarrow{E_2} A_2, \ldots, A_{n-1} \xrightarrow{E_n} B
\]

admits a composite if there exists a module \( A \xrightarrow{E} B \) and a cocartesian cell

\[
\mu: E_1 \times \cdots \times E_n \Rightarrow E
\]

\(^7\)This is analogous to the relationship between the universal properties that define weak \( p \)-cartesian transformations and \( p \)-cartesian transformations considered in Proposition 5.2.18.
characterized by the universal property that any cell of the form

\[
\begin{array}{cccccccc}
X & \xrightarrow{F_1} & \cdots & \xrightarrow{F_m} & A & \xrightarrow{E_1} & \cdots & \xrightarrow{E_n} & B & \xrightarrow{G_1} & \cdots & \xrightarrow{G_k} & Y \\
\downarrow f & & & & & & & & & & & & \downarrow g \\
C & \xrightarrow{=} & H & & & & & & & & & & & D
\end{array}
\]

factors uniquely through \(\mu\) as follows:

\[
\begin{array}{cccccccc}
X & \xrightarrow{F_1} & \cdots & \xrightarrow{F_m} & A & \xrightarrow{E_1} & \cdots & \xrightarrow{E_n} & B & \xrightarrow{G_1} & \cdots & \xrightarrow{G_k} & Y \\
\downarrow f & & & & & & & & \downarrow \exists & & & & \downarrow g \\
C & \xrightarrow{=} & H & & & & & & & & & & & D
\end{array}
\]

We have already seen one instance of this definition. Proposition 8.2.4 proves that units define nullary composites \(i: \emptyset \Rightarrow \text{Hom}_A\) in the virtual equipment of modules.

8.3.2. Observation (uniqueness of composites). Immediately from this universal property, composites are unique up to vertical isomorphism in the virtual equipment of modules. Recall from Lemma 8.1.19 that parallel modules are vertically isomorphic in the virtual equipment if and only if they are equivalent in the usual fibered sense.

A composite \(\mu: E_1 \times \cdots \times E_n \Rightarrow E\) can be used to reduce the domain of a cell by replacing any occurrence of the compatible sequence \(E_1 \times \cdots \times E_n\) from \(A\) to \(B\) by a single module \(E\). Particularly in the case of binary composites, we write \(E_1 \otimes E_2\) to denote the composite of the modules \(E_1\) and \(E_2\), appearing as the codomain of the cocartesian cell \(E_1 \times E_2 \Rightarrow E_1 \otimes E_2\). Note that the universal property of Definition 8.3.1 demands more than simply the condition that \(\mu: E_1 \times E_2 \Rightarrow E_1 \otimes E_2\) is universal among binary cells whose source is \(E_1 \times E_2\). As observed by Claudio Hermida, that weaker universal property is not enough to prove that the tensor product of modules is associative; see [50, §8.1] and Exercise 8.3.ii. By contrast, the universal property of Definition 8.3.1 allows us to use an expression like \(E_1 \otimes E_2 \otimes E_3\), without parentheses, for ternary and higher composites, since composition is “associative” in the following sense:

8.3.3. Lemma. Suppose the cells \(\mu_i: E_{i1} \times \cdots \times E_{i k_i} \Rightarrow E_i\) exhibit composites for \(i = 1, \ldots, n\).

(i) If \(\mu: E_1 \times \cdots \times E_n \Rightarrow E\) exhibits a composite then the composite cell

\[
E_{11} \times \cdots \times E_{nk_n} \xrightarrow{\mu_1 \times \cdots \times \mu_n} E_1 \times \cdots \times E_n \xrightarrow{\mu} E
\]

exhibits \(E\) as a composite of the sequence \(E_{11} \times \cdots \times E_{nk_n}\).

(ii) If the composite cell

\[
E_{11} \times \cdots \times E_{nk_n} \xrightarrow{\mu_1 \times \cdots \times \mu_n} E_1 \times \cdots \times E_n \xrightarrow{\mu} E
\]

exhibits \(E\) as a composite of the sequence \(E_{11} \times \cdots \times E_{nk_n}\), then \(\mu: E_1 \times \cdots \times E_n \Rightarrow E\) exhibits \(E\) as a composite of the sequence \(E_1 \times \cdots \times E_n\).
Proof. For (i), the required bijection factors as a composite of \( n + 1 \) bijections induced by the maps \( \mu_1, ..., \mu_n \) and \( \mu \). For (ii), the required bijection induced by \( \mu \) composes with the bijections supplied by the maps \( \mu_1, ..., \mu_n \) to a bijection and is thus itself a bijection. \qed

8.3.4. Remark. On account of the universal property of restrictions established in Proposition 8.2.1, to prove that a cell \( \mu: E_1 \times \cdots \times E_n \Rightarrow E \) exhibits a composite in a virtual equipment, it suffices to prove the factorization property of Definition 8.3.1 in the case where the vertical functors are identities, i.e., when all of the cells are “fibered.”

8.3.5. Definition. A compatible sequence of modules

\[
A \rightarrow A_1, A_1 \rightarrow A_2, \ldots, A_{n-1} \rightarrow B
\]

admits a strong composite if there exists a module \( A \rightarrow B \) and a fibered cell

\[
\mu: E_1 \times \cdots \times E_n \Rightarrow E
\]

represented by a functor \( ^r \mu: E_1 \times \cdots \times E_n \rightarrow E \) over \( A \times B \) that induces an equivalence of Kan complexes

\[
\text{Fun}_{X \times Y}(F_1 \times \cdots \times F_m \times E \times G_1 \times \cdots \times G_k, H) \sim \rightarrow \text{Fun}_{X \times Y}(F_1 \times \cdots \times F_m \times \mu \times G_1 \times \cdots \times G_k, H)
\]

for all compatible sequences of modules \( F_1, ..., F_m \) from \( X \) to \( A \) and \( G_1, ..., G_k \) from \( B \) to \( Y \) and all modules \( X \rightarrow Y \).

8.3.6. Lemma (strong composites are composites). If \( \mu: E_1 \times \cdots \times E_n \Rightarrow E \) is a strong composite then \( \mu \) exhibits \( E \) as the composite \( E_1 \otimes \cdots \otimes E_n \).

Proof. Given a compatible sequence of modules \( F_1, ..., F_m \) from \( X \) to \( A \) and a compatible sequence of modules \( G_1, ..., G_k \) from \( B \) to \( Y \) and form the horizontal composite two-sided fibrations

\[
\begin{array}{ccc}
F & \xrightarrow{p} & A \\
\downarrow{q} & & \downarrow{r} \\
X & & B \\
\end{array}
\quad \quad \quad \quad \begin{array}{ccc}
G & \xrightarrow{s} & \downarrow{r} \\
\downarrow{q} & & \downarrow{r} \\
B & & Y \\
\end{array}
\]

By Remark 8.3.4, it suffices to check the universal property of the composite cell for fibered maps whose codomain is a module \( X \rightarrow Y \). The hypothesis that \( \mu \) is a strong composite provides an equivalence of Kan complexes

\[
\text{Fun}_{X \times Y}(F \times E \times G, H) \sim \rightarrow \text{Fun}_{A \times B}(F \times E_1 \times \cdots \times E_n \times G, H)
\]

An equivalence of Kan complexes defines a bijection on path components, with each path component corresponding to an isomorphism class of 0-arrows by Observation 8.1.4. \qed

At first blush, the definition of “strong composite” appears unreasonably strong. Examples will arise from the same structure used in the proof of Proposition 8.2.4 to demonstrate that units define nullary composites in the virtual equipment of modules.
8.3.7. Lemma. Consider an \( n \)-ary module morphism \( \mu : \bigotimes_{A_1}^{A_n} E_n \Rightarrow E \) in the virtual equipment of modules whose codomain is a module from \( A \) to \( B \). If any representing map of spans

\[
\begin{array}{c}
E_1 \times \cdots \times E_n \\
\downarrow \mu^n \uparrow \\
A \times B
\end{array}
\]

admits a fibered adjoint over \( A \times B \), then \( \mu \) exhibits \( E \) as the strong composite \( \bigotimes_{A_1}^{A_n} E_n \).

Proof. To verify the universal property of Definition 8.3.5, consider a compatible sequence of modules \( F_1, \ldots, F_m \) from \( X \) to \( A \) and a compatible sequence of modules \( G_1, \ldots, G_k \) from \( B \) to \( Y \) and form the horizontal composite two-sided fibrations

\[
\begin{array}{cccccc}
F & \longrightarrow & A \\
\downarrow q & & \downarrow p \\
X & \longrightarrow & A \\
& & \uparrow \\
& & \downarrow \\
B & \longrightarrow & Y \\
\leftarrow & & \leftarrow \\
G & \leftarrow & B \\
\downarrow s & & \downarrow r \\
& & \uparrow \\
& & \downarrow \\
& & \leftarrow \\
& & \\
\end{array}
\]

The fibered adjunction of the statement pulls back along \( p \times s : F \times G \Rightarrow A \times B \) and pushes forward along \( q \times r : F \times G \Rightarrow X \times Y \) to a fibered adjoint to

\[
\begin{array}{c}
F \times E_1 \times \cdots \times E_n \times G \\
\downarrow F \times (\mu \times G) \uparrow \\
X \times Y
\end{array}
\]

Via Remark 8.3.4, it suffices to verify the universal property of the composite for modules \( X \Rightarrow Y \). Since modules are discrete, applying \( \text{Fun}_{X \times Y}(\_ , H) \) transforms this fibered adjunction into an adjoint equivalence

\[
\text{Fun}_{X \times Y}(F \times E \times G, H) \xrightarrow{(F \times \mu \times G)} \text{Fun}_{X \times Y}(F \times E_1 \times \cdots \times E_n \times G, H).
\]

establishing the universal property that characterizes strong composites. \( \square \)

Strong composites satisfy an associativity property analogous to Lemma 8.3.3 with a similar proof:

8.3.8. Lemma. Suppose the cells \( \mu_i : E_{i1} \times \cdots \times E_{ik_i} \Rightarrow E_i \) exhibit strong composites for \( i = 1, \ldots, n \).

(i) If \( \mu : E_1 \times \cdots \times E_n \Rightarrow E \) exhibits a strong composite then the composite cell

\[
\begin{array}{c}
E_{11} \times \cdots \times E_{nk_n} \\
\downarrow \mu_1 \times \cdots \times \mu_n \\
E_1 \times \cdots \times E_n \\
\downarrow \mu \\
E
\end{array}
\]

exhibits \( E \) as a strong composite of the sequence \( E_{11} \times \cdots \times E_{nk_n} \).

(ii) If the composite cell

\[
\begin{array}{c}
E_{11} \times \cdots \times E_{nk_n} \\
\downarrow \mu_1 \times \cdots \times \mu_n \\
E_1 \times \cdots \times E_n \\
\downarrow \mu \\
E
\end{array}
\]

exhibits \( E \) as a strong composite of the sequence \( E_{11} \times \cdots \times E_{nk_n} \), then \( \mu : E_1 \times \cdots \times E_n \Rightarrow E \) exhibits \( E \) as a strong composite of the sequence \( E_1 \times \cdots \times E_n \).

Proof. Exercise 8.3.iii. \( \square \)
We now turn to examples. The trivial instances of composites are easily verified:

8.3.9. LEMMA. In the virtual equipment of modules:

(i) The units \( t : \emptyset \Rightarrow \text{Hom}_A \) of Proposition 8.2.4 define nullary strong composites.
(ii) A unary cell \( \mu : E \Rightarrow F \) is a composite if and only if it is an isomorphism in the vertical category of modules from \( A \) to \( B \) and module maps over identity functors, that is, if and only if the modules \( E \) and \( F \) are equivalent as spans. In this case \( \mu : E \Rightarrow F \) is a strong composite.

Proof. Exercise 8.3.iv.

As one might hope, the unit modules \( A \Rightarrow A \text{Hom}_A \) are units for the composition notion introduced in Definition 8.3.1 in the following sense: for any module \( A \Rightarrow B \), there is a strong composite relation \( \text{Hom}_A \otimes E \otimes \text{Hom}_B \simeq E \).

8.3.10. LEMMA (composites with units). For any module \( A \Rightarrow B \) the unique cell \( E \text{Hom}_A \otimes E \text{Hom}_B \Rightarrow E \) defined using the universal property of the unit cell

\[
\begin{array}{ccc}
A & \xrightarrow{E} & B \\
\downarrow \text{Hom}_A & & \downarrow \text{Hom}_B \\
A & \xrightarrow{E} & B \\
\downarrow \text{E} & & \downarrow \text{E} \\
A & \xrightarrow{E} & B
\end{array}
\]

displays \( E \) as the strong composite \( \text{Hom}_A \otimes E \otimes \text{Hom}_B \).

Proof. The result is immediate from Lemma 8.3.8(ii) and Lemma 8.3.9.

8.3.11. PROPOSITION. Let \( A \Rightarrow B \) be a module encoded by the span \( A \leftarrow E \rightarrow B \). Then the binary module map

\[
\begin{array}{ccc}
A & \xrightarrow{E} & B \\
\downarrow \text{Hom}_A & & \downarrow \text{Hom}_B \\
A & \xrightarrow{E} & B \\
\downarrow \text{E} & & \downarrow \text{E} \\
A & \xrightarrow{E} & B
\end{array}
\]

represented by composite left and right adjoints of Theorem 7.1.4(iii) exhibits a strong composite \( \text{Hom}_A(q,A) \otimes \text{Hom}_B(B,p) \simeq E \) expressing the module as the composite of the modules representing its legs.

Proof. Immediate from Theorem 7.1.4(iii) and Lemma 8.3.7 applied twice.

8.3.12. REMARK. Nothing in the proof of Proposition 8.3.11 requires that the span \( A \leftarrow E \rightarrow B \) is actually a module, rather than a mere two-sided fibration, except for the interpretation that \( \mu \) is a binary cell in the virtual equipment of modules. For any two-sided fibration \( A \leftarrow E \rightarrow B \), it is still the case that restriction along the map of spans \( ^*\mu \) defines a bijection between maps of two-sided isofibrations whose source includes the span \( E \) and whose codomain is a module and maps whose source

\^[8]

Of course the composite of a left and a right adjoint is not an adjoint but here we’re effectively composing adjoint equivalences in which case the direction does not matter.
instead includes $\text{Hom}_A(q, A) \times \text{Hom}_B(B, p)$. In particular, for any compatible sequence of modules $E_1 \times \cdots \times E_n$ from $A$ to $B$ whose span composite defines the two-sided fibration $A \leftrightarrow E \rightarrow B$, there is a bijection between module maps

$$
\begin{array}{c}
\begin{array}{c}
X \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
A \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
E \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
B \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
Y \\
\Downarrow \phi
\end{array}
\end{array}
\end{array}
$$

and module maps

$$
\begin{array}{c}
\begin{array}{c}
X \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
A \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
E \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
B \\
\Downarrow \phi
\end{array}
\end{array}
\begin{array}{c}
\begin{array}{c}
Y \\
\Downarrow \phi
\end{array}
\end{array}
\end{array}
$$

in the virtual equipment of modules.

8.3.13. REMARK. We will make use of another description of the composition map $\mu : \text{Hom}_A(q, A) \times \text{Hom}_B(B, p) \Rightarrow E$ in Proposition 8.3.11 and Remark 8.3.12. The comma cones for $\text{Hom}_A(q, A)$ and $\text{Hom}_B(B, p)$

define a pair of 2-cells to which the premises of Theorem 7.1.4(iv) apply. The conclusion asserts that there is a well-defined fibered isomorphism class of functors $\mu : \text{Hom}_A(q, A) \times \text{Hom}_B(B, p) \rightarrow E$ defined by taking the $q$-cocartesian lift of the left comma cone, composing with the right comma cone, and then taking the codomain of a $p$-cartesian lift of this composite cell — or by first taking the $p$-cartesian lift, composing, and then taking the domain of a $q$-cartesian lift of this composite — this being the functor $\ell r \simeq r \ell$ in the notation of Theorem 7.1.4(iii). In the case where $A \rightarrow B$ is itself a comma module, the resulting fibered isomorphism class of functors $\mu$ is the one that classifies the 2-cell defined by pasting the displayed composite with the comma cone for $E$.

Any virtual double category has a vertical identity cell for each horizontal arrow $A \rightarrow B$ whose vertical boundary arrows are identities. In a virtual equipment, we also have a horizontal unary unit cell for each vertical arrow $f : A \rightarrow B$ whose horizontal boundary is given by the unit modules $A \rightarrow A$ and $B \rightarrow B$ of Proposition 8.2.4 that is defined from the nullary unit cells:

8.3.14. DEFINITION. Using the unit modules in $\text{Mod}(\mathcal{K})$, for any functor $f : A \rightarrow B$ we may define a unary unit cell as displayed below-left by appealing to the universal property of the nullary unit cell.
\[ \iota : \emptyset \Rightarrow \text{Hom}_A \] for \( A \) in the equation below-right:

\[
\begin{array}{c}
A \xrightarrow{\text{Hom}_A} A \\
\downarrow \downarrow \downarrow \downarrow \\
B \xrightarrow{\text{Hom}_B} B
\end{array}
\quad \Leftrightarrow \quad
\begin{array}{c}
A \xrightarrow{f} A \\
\downarrow \downarrow \downarrow \downarrow \\
B \xrightarrow{f} B
\end{array}
\quad \quad
\begin{array}{c}
A \xrightarrow{\iota} A \\
\downarrow \downarrow \downarrow \downarrow \\
B \xrightarrow{\iota} B
\end{array}

In the characterization of Lemma 8.1.18, both sides of the pasting equality defining the unary unit cell correspond to the identity 2-cell \( A \xRightarrow{\iota, \text{id}_f} B \).

As one might hope, the unit cells are units for the vertical composition of cells in the virtual equipment of modules.

8.3.15. **Lemma (composition with unit cells).** Any cell \( \alpha \) as below-right equals the pasted composite below-left:

\[
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n
\end{array}
\quad =
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n
\end{array}
\]

\[
\begin{array}{c}
A_0 \xrightarrow{f, \text{id}_f} A_0 \xrightarrow{\alpha} A_1 \xrightarrow{g} A_2 \quad \cdots \quad \xrightarrow{g} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
B \xrightarrow{E} C
\end{array}
\quad =
\begin{array}{c}
A_0 \xrightarrow{f, \text{id}_f} A_0 \xrightarrow{\alpha} A_0 \xrightarrow{g} A_1 \xrightarrow{g} A_2 \quad \cdots \quad \xrightarrow{g} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
B \xrightarrow{E} C
\end{array}
\]

**Proof.** By Definition 8.3.14 and the laws for composition with identity cells in a virtual double category stated in Definition 8.1.10, the left-hand composite of the statement equals the left-hand composite cell displayed below and the right-hand side of the statement equals the right-hand composite cell displayed below:

\[
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n
\end{array}
\quad =
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
A_0 \xrightarrow{E_1} A_1 \quad \cdots \quad \xrightarrow{E_n} A_n
\end{array}
\]

By Lemma 8.3.10, the left-hand side equals the right-hand side. \( \square \)
8.3.16. Definition (horizontal composition of cells). If given a horizontally compatible sequence of unary cells

\[
\begin{array}{cccccc}
& E_1 & A_1 & E_2 & A_2 & \cdots & A_n \\
A_0 & \downarrow f_0 & \downarrow \| \alpha_1 \downarrow f_1 & \downarrow \| \alpha_2 \downarrow f_2 & \cdots & \downarrow \| \alpha_n \downarrow f_n \\
B_0 & \downarrow f_0 & \downarrow \| \alpha_1 \cdots \alpha_n \downarrow f_n \\
& B_1 & \cdots & B_n \\
\end{array}
\]

for which the compatible sequences \( E_1 \times \cdots \times E_n \) and \( F_1 \times \cdots \times F_n \) both admit composites, then there exists a **horizontal composite unary cell** \( \alpha_1 \ast \cdots \ast \alpha_n \) that is uniquely determined up to the specification of the composites \( \circ : E_i \times \cdots \times E_n \Rightarrow E \) and \( F_1 \times \cdots \times F_n \Rightarrow F \) by the pasting identity:

\[
A_0 \rightarrow A_1 \rightarrow \cdots \rightarrow A_n = B_0 \rightarrow B_1 \rightarrow \cdots \rightarrow B_n
\]

(8.3.17)

By an argument very similar to the proof of Lemma 8.3.15 using the composites of Lemma 8.3.10, the horizontal composite \( \text{Hom}_{f} \ast \alpha \ast \text{Hom}_{g} \) of a unary cell \( \alpha \) with the unit cells \( \text{Hom}_{f} \) and \( \text{Hom}_{g} \) at its vertical boundary functors recovers \( \alpha \); see Exercise 8.3.v. Using the horizontal composition of unary cells of Definition 8.3.16, we can understand \( \text{Mod}(\mathcal{K}) \) to contain various “vertical” and “horizontal” bicategories.

8.3.18. Proposition (the vertical 2-category in the virtual equipment). Any virtual equipment contains a **vertical 2-category** whose objects are the objects of the virtual equipment, whose arrows are the vertical arrows, and whose 2-cells are those unary cells

\[
\begin{array}{cccccc}
A & \rightarrow & A \\
\downarrow \text{Hom}_A & \downarrow \| \downarrow f \\
B & \rightarrow & B \\
\downarrow \text{Hom}_B & \\
\end{array}
\]

whose horizontal boundary arrows are given by the unit modules.

Proof. To prove that these structures define a 2-category we must define “horizontal” composition of 2-cells (composing along a boundary 0-cell) and “vertical” composition of 2-cells (composing along a boundary 1-cell), to adopt the standard terminology from Definition B.1.1. The “horizontal” composition in the 2-category is defined via the vertical composition in the virtual double category described in Definition 8.1.10. The “vertical” composition in the 2-category is defined by Definition 8.3.16. To see that this yields a 2-category and not a bicategory note that any bicategory in which the composition of 1-cells is strictly associative and unital is a 2-category; in this case, the 1-cells are the vertical arrows of the virtual double category, which do indeed compose strictly.

Proposition 8.4.11 will prove that the vertical 2-category in the virtual equipment \( \text{Mod}(\mathcal{K}) \) is isomorphic to the homotopy 2-category \( \mathcal{K} \).
8.3.19. **Remark** (horizontal bicategories in the virtual equipment). Via Definition 8.3.16, a virtual equipment can also be understood to contain various “horizontal” bicategories, defined by taking the 1-cells to be composable modules and the 2-cells to be unary module maps whose vertical boundary functors are identities. Particular horizontal bicategories of interest are described in Definition 8.4.12.

**Exercises.**

8.3.i. **Exercise.** Extending Exercise 8.1.ii, prove that in a virtual double category arising from an actual double category that every compatible sequence of horizontal morphisms admits a composite in the sense of Definition 8.3.1.

8.3.ii. **Exercise ([50, 8.5],[73, 3.3.4]).**

(i) Suppose that for every compatible sequence $E_1 \times \cdots \times E_n$ in a virtual equipment there exists a cell $\mu: E_1 \times \cdots \times E_n \Rightarrow E$ that is *weakly cocartesian* meaning that every $n$-ary cell $E_1 \times \cdots \times E_n \Rightarrow G$ factors uniquely through $\mu$ via a unary cell $E \Rightarrow G$. If moreover the weakly cocartesian cells are closed under composition in the virtual double category, show that every weakly cocartesian cell is in fact cocartesian, satisfying the universal property of Definition 8.3.1, and conclude that the virtual equipment then admits all composites.

(ii) Suppose $\mathcal{K}$ is an $\infty$-cosmos in which every two-sided fibration $A \xleftarrow{q} E \xrightarrow{p} B$ can be reflected into a module, meaning that there exists a map of spans

$$
\begin{array}{c}
\begin{array}{ccc}
A & \xleftarrow{q} & E \\
\mu & & \downarrow \mu \\
\downarrow q & & \downarrow \mu & \\
\tilde{E} & \xrightarrow{\mu} & B \\
\end{array}
\end{array}
$$

with $\tilde{E}$ a module so that for every module $A \xrightarrow{H} B$, $\mu$ induces an equivalence of Kan complexes

$$
\text{Fun}_{A \times B}(\tilde{E}, H) \xrightarrow{\sim \mu} \text{Fun}_{A \times B}(E, H).
$$

Conclude that the virtual equipment $\text{Mod}(\mathcal{K})$ has all composites.

8.3.iii. **Exercise.** Prove Lemma 8.3.8.

8.3.iv. **Exercise.** Prove Lemma 8.3.9.

8.3.v. **Exercise.** For any unary cell

$$
\begin{array}{ccc}
A & \xrightarrow{E} & B \\
\downarrow f & \downarrow \alpha & \downarrow g \\
C & \xrightarrow{F} & D
\end{array}
$$

show that the horizontal composite $\text{Hom}_f \ast \alpha \ast \text{Hom}_g$ equals $\alpha$.

**8.4. Representable Modules**

Any vertical arrow $f: A \rightarrow B$ in a virtual equipment has a pair of associated horizontal arrows $B \xrightarrow{\text{Hom}_f(B,f)} A$ and $A \xrightarrow{\text{Hom}_g(f,B)} B$, defined as restrictions of the horizontal unit arrows, that have universal
properties similar to companions and conjoints in an ordinary double category. In the virtual equipment of modules, these are sensibly referred to as the left and right representations of a functor as a module, using terminology and notation because these coincide exactly with the left and right representables first introduced as comma ∞-categories in §3.5 and reintroduced as modules in Definition 7.4.8.

8.4.1. PROPOSITION (companion and conjoint relations for representables). To any functor $f: A \to B$ in the virtual equipment of modules, there exist canonical restriction cells displayed below-left and application cells displayed below-right

$$
\begin{array}{c}
\text{Hom}_B(f,B) \quad \text{Hom}_B(B,f) \\
\downarrow \rho \downarrow f \quad \downarrow \rho \\
B \quad B
\end{array}
\begin{array}{c}
\text{Hom}_A(f,B) \quad \text{Hom}_A(B,f) \\
\downarrow \kappa \downarrow f \quad \downarrow \kappa \\
A \quad A
\end{array}
\begin{array}{c}
\text{Hom}_A \quad \text{Hom}_A \\
\downarrow \rho \downarrow f \quad \downarrow \rho \\
A \quad A
\end{array}
\begin{array}{c}
\text{Hom}_B(f,B) \quad \text{Hom}_B(B,f) \\
\downarrow \kappa \downarrow f \quad \downarrow \kappa \\
B \quad B
\end{array}
$$

defining unary module maps between the unit modules $A \to A$ and $B \to B$ and the left and right representable modules $B \to A$ and $A \to B$. These satisfy the identities:

\begin{align}
&\text{Hom}_A \quad \text{Hom}_A \\
&\downarrow \rho \quad \downarrow f \quad \downarrow \rho \quad \downarrow \rho \\
&\text{Hom}_B(f,B) \quad \text{Hom}_B(B,f) \quad \text{Hom}_B \quad \text{Hom}_B
\end{align}

(8.4.2)

and

\begin{align}
&\text{Hom}_B(f,B) \quad \text{Hom}_B(B,f) \\
&\downarrow \rho \downarrow f \downarrow \rho \downarrow \rho \downarrow \rho \\
&\text{Hom}_B(f,B) \quad \text{Hom}_B(B,f) \quad \text{Hom}_B \quad \text{Hom}_B
\end{align}

(8.4.3)

PROOF. The unary module maps $\kappa$ are defined by the equations (8.4.2) by appealing to the universal property of the restriction cells in Proposition 8.2.1. The relations (8.4.3) could also be verified directly from the axioms of Theorem 8.2.6 via Propositions 8.2.4 and Lemmas 8.3.10 and 8.3.10. For sake of variety, we appeal to Lemma 8.1.18 to characterize each of the cells in the virtual equipment as 2-cells in the homotopy 2-category.

We prove this for the right representables; the co-dual then proves this for the left representables. By Remark 8.3.13, the binary module morphism on the left-hand side of the rightmost equality of
(8.4.3) represents the 2-cell below-left, while the right-hand composite is below-right:

By the definition of the induced functor \( f \kappa^2 : A^2 \to \text{Hom}_B(B, f), \phi f \kappa^2 = f \kappa \) and by the definition of the comma cone \( \phi \) for \( \text{Hom}_B(B, f), \phi = \kappa \rho \). Thus, the left-hand side equals the right-hand side. □

The companions and conjoints of Proposition 8.4.1 can be deployed to “bend” vertical functors into horizontal modules, producing bijections between cells whose boundaries involve these arrows. The following result is sometimes called the “spider lemma,” in reference to a graphical calculus that can be used to illustrate virtual equipment cells and their composites [85].

8.4.4. THEOREM (spider lemma). In the virtual equipment of modules there are natural bijections between cells of the following four forms

implemented by composing with the canonical cells \( \kappa \) and \( \rho \) of Proposition 8.4.1 and with the composition and nullary cells associated to the units.

PROOF. To save space, we illustrate the construction of these bijections in the case where the source is given by a single module \( E \) from \( A \) to \( B \) rather than a compatible sequence. The construction is the same in the general case.
The composite bijection displayed vertically in the statement carries cells \( \alpha \) and \( \beta \) to the cells displayed below-left and below-right respectively:

By Proposition 8.4.1 and Lemma 8.3.15

The other composite is:
By Lemma 8.3.10, we have

\[
\begin{array}{cccccccc}
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\mu & & \downarrow\mu & & \downarrow\mu & & \downarrow\mu \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\rho & & \downarrow\rho & & \downarrow\rho & & \downarrow\rho \\
F & \xrightarrow{F} & D \\
\end{array}
\]

since both composites equal \(\beta\). By the universal property of the unit cells in Proposition 8.2.4, the bottom two rows of these diagrams are equal, so we may substitute the bottom two rows of the right-hand diagram for the bottom two rows of (8.4.5) to obtain:

\[
\begin{array}{cccccccc}
\hat{\beta} = \begin{array}{cccccccc}
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\mu & & \downarrow\mu & & \downarrow\mu & & \downarrow\mu \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\rho & & \downarrow\rho & & \downarrow\rho & & \downarrow\rho \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
\end{array}
\end{array}
\]

By Proposition 8.4.1 and Lemma 8.3.10 this reduces to \(\beta\).

\[
\begin{array}{cccccccc}
\hat{\beta} = \begin{array}{cccccccc}
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\mu & & \downarrow\mu & & \downarrow\mu & & \downarrow\mu \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\beta & & \downarrow\beta & & \downarrow\beta & & \downarrow\beta \\
C & \xrightarrow{\Hom_C(f, C)} & A & \xrightarrow{E} & B & \xrightarrow{\Hom_D(D,g)} & D \\
\downarrow\rho & & \downarrow\rho & & \downarrow\rho & & \downarrow\rho \\
\end{array}
\end{array}
\]

By vertically bisecting this construction, one obtains the one-sided bijections of the statement. \(\square\)

We frequently apply this result in the following form:

8.4.6. Corollary. Given a compatible sequence of modules \(E_1 \times \cdots \times E_n\) from \(A\) to \(B\), a module \(F\) from \(C\) to \(D\), and functors \(f\): \(A \to C\) and \(g\): \(B \to D\), there is a bijection between fibered module maps
\( \text{Hom}_C(f, C) \times E_1 \times \cdots \times E_n \times \text{Hom}_D(D, g) \Rightarrow F \) and fibered module maps \( E_1 \times \cdots \times E_n \Rightarrow F(g, f) \), i.e., between cells

\[
\begin{array}{ccccccc}
C & \to & A & \to & \cdots & \to & B & \to & D \\
\downarrow & & \downarrow & & & & \downarrow & & \downarrow \\
C & \to & F & \to & D & \to & A & \to & B \\
\end{array}
\]

PROOF. Combine Theorem 8.4.4 with Proposition 8.2.1.

8.4.7. PROPOSITION. For any module \( A \xrightarrow{E} B \) and pair of functors \( a \colon X \to A \) and \( b \colon Y \to B \), the strong composite \( \text{Hom}_A(A, a) \otimes E \otimes \text{Hom}_B(b, B) \) exists and is given by the restriction \( E(b, a) \), with the ternary strong composite map \( \mu : \text{Hom}_A(A, a) \times E \times \text{Hom}_B(b, B) \Rightarrow E(b, a) \) defined by the universal property of the restriction by the pasting diagram:

\[
\begin{array}{ccccccc}
X & \to & A & \xrightarrow{E} & B & \xrightarrow{Hom_B(b, B)} & Y \\
\downarrow \mu & & \downarrow & & \downarrow & & \downarrow \\
X & \xrightarrow{E(b, a)} & Y & \xrightarrow{b} & B & \xrightarrow{Hom_B(b, B)} & B \\
\end{array}
\]

PROOF. The horizontal composite two-sided fibration of the compatible sequence is

\[
\begin{array}{cccc}
\text{Hom}_A(A, a) \times E \times \text{Hom}_B(b, B) & \to & E \\
\text{Hom}_A(A, a) & \to & E & \to & \text{Hom}_B(b, B) \\
\end{array}
\]

from which we see that the binary composite cell

\[
\begin{array}{cccc}
\text{Hom}_A(A, a) \times \text{Hom}_B(b, B) & \to & E \\
\xrightarrow{\mu} & \xrightarrow{a} & E & \xrightarrow{b} & \text{Hom}_B(b, B) \\
\end{array}
\]

of Proposition 8.3.11 pulls back along \( a \times b : X \times Y \to A \times B \) to define the map \( \mu \). By Lemma 8.3.7, we conclude that \( \mu : \text{Hom}_A(A, a) \times E \times \text{Hom}_B(b, B) \Rightarrow E(b, a) \) is a strong composite.

When one of the three modules appearing in the source of the ternary composite of Proposition 8.4.7 is a unit module, we can use Lemma 8.3.8 and the nullary composite cell associated with the unit to reduce this ternary composite to a binary composite; see Exercise 8.4.iii. This argument proves the following corollaries:
8.4.8. **Corollary.** For any cospan of functors $C \xrightarrow{g} A \xleftarrow{f} B$, the comma module $\text{Hom}_A(f, g)$ factors as a strong composite

\[ \text{Hom}_A(A, g) \otimes \text{Hom}_A(f, A) \simeq \text{Hom}_A(f, g). \]

\[ \square \]

A similar reduction proves that right representable modules can always be composed with each other and dually left representable modules can always be composed with each other:

8.4.9. **Corollary.** Any composable pair of functors $A \xrightarrow{f} B \xrightarrow{g} C$ defines a strongly composable pair of right-represented modules and a strongly composable pair of left-represented modules

\[ \text{Hom}_B(B, f) \otimes \text{Hom}_C(C, g) \simeq \text{Hom}_C(C, gf) \quad \text{and} \quad \text{Hom}_C(g, C) \otimes \text{Hom}_B(f, B) \simeq \text{Hom}_B(gf, C). \]

\[ \square \]

Combining this result with Proposition 8.3.11 provides a generalization of Theorem 3.5.12, which allows us to detect representable modules.

8.4.10. **Proposition.** Let $A \xleftarrow{q} E \xrightarrow{p} B$ encode a module.

(i) The module $A \xrightarrow{E} B$ is right representable if and only if its left leg $q : E \rightarrow A$ has a right adjoint $r : A \rightarrow E$ in which case $E \simeq \text{Hom}_B(B, pr)$.

(ii) The module $A \xrightarrow{E} B$ is left representable if and only if its right leg $p : E \rightarrow B$ has a left adjoint $\ell : B \rightarrow E$ in which case $E \simeq \text{Hom}_A(q\ell, A)$.

**Proof.** Lemma 3.5.9 proves that the claimed adjoints to the legs $p_1 : \text{Hom}_B(B, f) \rightarrow A$ and $p_0 : \text{Hom}_B(f, B) \rightarrow A$ of left or right representable modules exist, so it remains only to prove the converse. By Proposition 8.3.11, any module $E$ can be expressed as a composite $\text{Hom}_A(q, A) \otimes \text{Hom}_B(B, p) \simeq E$ of the left representation of its left leg followed by the right representation of its right leg. If $q \dashv r$, then by Proposition 4.1.1 $\text{Hom}_A(q, A) \simeq \text{Hom}_E(E, r)$ as modules from $A$ to $E$, so by Lemma 8.3.3, $\text{Hom}_E(E, r) \otimes \text{Hom}_B(B, p) \simeq E$. By Corollary 8.4.9, $\text{Hom}_E(E, r) \otimes \text{Hom}_B(B, p) \simeq \text{Hom}_B(B, pr)$ so by Lemma 8.3.3 again, $\text{Hom}_B(B, pr) \simeq E$. The case of left representability is dual. \[ \square \]

Finally, we revisit the “cheap” version of the Yoneda lemma presented in Corollary 3.5.11, which encodes natural transformations in the homotopy 2-category as maps of represented modules.

8.4.11. **Proposition.** For any parallel pair of functors there are natural bijections between 2-cells in the homotopy 2-category

\[ A \xrightarrow{f} B \xleftarrow{g} \]

and cells in the virtual equipment of modules:

\[
\begin{array}{cccc}
\text{Hom}_B(B, f) & & \text{Hom}_A & & \text{Hom}_B(B, g) \\
A \rightarrow B & \leftrightarrow & A \rightarrow A & \leftrightarrow & B \rightarrow A \\
\text{Hom}_B(B, g) & & \text{Hom}_B & & \text{Hom}_B(f, B) \\
A \rightarrow B & \leftrightarrow & B \rightarrow B & \leftrightarrow & B \rightarrow A
\end{array}
\]
PROOF. The bijections in $\textbf{Mod}(\mathcal{K})$ can then be derived from Theorem 8.4.4 and Corollary 8.4.6. The bijection between 2-cells in the homotopy 2-category and unary module maps between left or right representables is simply a restatement of Corollary 3.5.11. Lemma 8.1.18 and Proposition 8.2.4 combine to give an alternate proof of the bijection between 2-cells in the homotopy 2-category and the cells displayed in the center. □

8.4.12. DEFINITION (the covariant and contravariant embeddings). Proposition 8.4.11 defines the action on 2-cells of two identity-on-objects locally fully faithful homomorphisms

$$h\mathcal{K} \rightarrow \textbf{Mod}(\mathcal{K})$$

$$A \rightarrow B \mapsto A \rightarrow B$$

that embed the homotopy 2-category fully faithfully into the sub “bicategory” of $\textbf{Mod}(\mathcal{K})$ containing only those unary cells whose vertical boundaries are identities.

This substructure of $\textbf{Mod}(\mathcal{K})$ isn’t quite a bicategory because not all horizontally composable modules can be composed, but if we restrict only to the right representable modules or only to the left representable modules, then by Corollary 8.4.9 the composites do exist and moreover the embeddings are horizontally as well as vertically pseudofunctorial: given $A \rightarrow B \rightarrow C$ we have $\text{Hom}_B(B, f) \otimes \text{Hom}_C(C, g) = \text{Hom}_C(C, gf)$ and $\text{Hom}_B(g, C) \otimes \text{Hom}_B(f, B) \simeq \text{Hom}_C(gf, C)$. We refer to these as the covariant and contravariant embeddings respectively.

As described in Remark 8.3.19, $\textbf{Mod}(\mathcal{K})$ can be understood to contain genuine bicategories whose 2-cells are unary cells between right-represented modules (or between left-represented modules) whose vertical boundaries are identities. In this way, the covariant and contravariant embeddings can be understood to define genuine bicategorical homomorphisms.

There is a third locally fully faithful embedding of the homotopy 2-category $h\mathcal{K}$ into $\textbf{Mod}(\mathcal{K})$ that is identity on objects, sends $f : A \rightarrow B$ to the corresponding vertical 1-cell, and uses the third bijection of Proposition 8.4.11 to define the action on 2-cells. Since $\text{Hom}_A \otimes \text{Hom}_A \simeq \text{Hom}_A$, the unary cells in this image of this embedding can be composed horizontally as well as vertically, and this embedding is functorial in both directions: vertical composites of natural transformations in $h\mathcal{K}$ coincide with horizontal composites of unary cells and horizontal composites of natural transformations in $h\mathcal{K}$ coincide with vertical composites of unary cells. The image is precisely the vertical 2-category of Proposition 8.3.18. We will make much greater use of the covariant and contravariant embeddings of Definition 8.4.12 however.

Exercises.

8.4.i. EXERCISE. Prove Proposition 8.4.1 in any virtual equipment, without appealing to Lemma 8.1.18.

8.4.ii. EXERCISE. State and prove a generalization of Theorem 8.4.4 in which the bottom $n + 2$-ary cell appearing in the statement is not fibered, but has vertical boundary defined by an arbitrary pair of non-identity functors.

8.4.iii. EXERCISE. Prove a binary version of Proposition 8.4.7: that for any module $A \rightarrow B$ and any functors $a : X \rightarrow A$ and $b : Y \rightarrow B$ the strong composites $\text{Hom}_A(A, a) \otimes E$ and $E \otimes \text{Hom}_B(b, B)$ exist and are given by the restrictions $E(1, a)$ and $E(b, 1)$, respectively.
8.4.iv. EXERCISE. Prove the non-strong version of Proposition 8.4.7 in any virtual equipment, without appealing to Lemma 8.3.7.

8.4.v. EXERCISE. For any functor $f: A \to B$, define a canonical unary cell $\eta: \text{Hom}_A \Rightarrow \text{Hom}_B(f, f) \simeq \text{Hom}_B(f, f) \otimes \text{Hom}_B(f, B)$ and a binary cell $\epsilon: \text{Hom}_B(f, B) \times \text{Hom}_B(B, f) \Rightarrow \text{Hom}_B$. Use this data to demonstrate that the modules $A \Rightarrow \text{Hom}_B(B, f)$ and $B \Rightarrow \text{Hom}_B(f, B)$ are “adjoint” in a suitable sense.
Mac Lane famously asserted that "all concepts are Kan extensions" \cite[§X.7]{MacLane1971} — at least in category theory. Kelly later amended this to assert that the \emph{pointwise Kan extensions}, which he calls simply "Kan extensions" are the important ones, writing "Our present choice of nomenclature is based on our failure to find a single instance where a [non-pointwise] Kan extension plays any mathematical role whatsoever" \cite[§4]{Kelly1964}. Using the calculus of modules we can now add the theory of pointwise Kan extensions of functors between $\infty$-categories to the basic $\infty$-category theory developed in Part I.

Right and left extensions of a functor $f: A \to C$ along a functor $k: A \to B$ can be defined internally to any 2-category — at this level of generality the eponym "Kan" is typically dropped. We review this notion in Definition 9.1.1. However, in the homotopy 2-category of an $\infty$-cosmos, the universal property defining left and right extensions is not strong enough, and indeed the correct universal property is associated to the stronger notion of a \emph{pointwise extension}, for which the values of a right or left extension at an element of $B$ can be computed as limits or colimits indexed by the appropriate comma $\infty$-category; see Proposition 9.5.3 for a precise statement.

Our aim in this chapter is to define and study pointwise extensions for functors between $\infty$-categories. In fact, we give multiple definitions of pointwise extension. One is fundamentally 2-categorical: a pointwise extension is an ordinary 2-categorical extension in the homotopy 2-category that is stable under pasting with comma squares. Another definition is that a 2-cell defines a pointwise right extension if and only if its image under the covariant embedding into the virtual equipment of modules defines a right extension there. Theorem 9.3.3 proves that these two notions coincide.

In §9.1, we introduce right liftings and right extensions in the virtual equipment of modules and being to familiarize ourselves with these notions. Before turning our attention to pointwise extensions, we first introduce exact squares in §9.2, a class of squares in the homotopy 2-category that include comma squares and which will be used to characterize the pointwise extensions internally to the homotopy 2-category. Pointwise extensions are introduced in a variety of equivalent ways in §9.3 and applied in §9.4 to develop a few aspects of the formal theory of $\infty$-categories.

The bulk of the formal category theory considered in §9.4 concerns adjunctions and fully faithful functors, revisiting well-trodden ground. The vital applications of pointwise right and left extensions arrive in §9.5 when we are finally able to define limits and colimits of $\infty$-category indexed diagrams in general $\infty$-cosmoi, that are not necessarily cartesian closed. In §9.6, we introduce a more general class of limits and colimits for diagrams between $\infty$-categories that are \emph{weighted} by an arbitrary module and quickly establish the key components of the calculus of weighted limits and colimits. These results can be understood as revealing that many aspects of $\infty$-category are automatically enriched over discrete $\infty$-categories—better known as "$\infty$-groupoids" in $\infty$-cosmoi of $(\infty, 1)$-categories.

There is one question we do not address in this chapter: namely criteria that guarantee the existence of pointwise left and right extensions. We return to this topic in §12.3 where we take advantage of the results about pointwise-defined universal properties established in Chapter 12 to prove the expected
converse to Proposition 9.5.3 in $\infty$-cosmoi of $(\infty, 1)$-categories, reducing the question of the existence of pointwise left or right extensions to the existence of certain colimits or limits.

9.1. Liftings and Extensions of Modules

In this section we introduce and study liftings and extensions in the virtual equipment of modules. To motivate Definition 9.1.2, we briefly recall the standard 2-categorical definition:

9.1.1. Definition. A right extension of a 1-cell $f: A \to C$ along a 1-cell $k: A \to B$ is given by a pair $(r: B \to C, \nu: r k \Rightarrow f)$ as below-left

\[
\begin{align*}
A & \xrightarrow{f} C \\
\downarrow k & \quad \downarrow \nu \\
B & \quad r \\
\end{align*}
\]

so that any similar pair as above-center factors uniquely through $\nu$ as above right.

Dually, a left extension of a 1-cell $f: A \to C$ along a 1-cell $k: A \to B$ is given by a pair $(\ell: B \to C, \lambda: f \Rightarrow \ell k)$ as below-left

\[
\begin{align*}
A & \xrightarrow{f} C \\
\downarrow k & \quad \downarrow \lambda \\
B & \quad \ell \\
\end{align*}
\]

so that any similar pair as above-center factors uniquely through $\lambda$ as above right.

The op-duals of Definition 9.1.1 define right and left lifting diagrams in any 2-category. Analogous notions of right extension and right lifting can be defined for horizontal morphisms in a virtual double equipment, where in the presence of restrictions of modules it suffices to consider “fibered” cells, whose vertical functors are identities. We specialize our language to the virtual equipment of modules, as this will be the case of interest:

9.1.2. Definition. A right extension of a module $A \to R_C$ along a module $A \to R_B$ consists of a pair given by a module $B \to R_C$ together with a binary cell

\[
\begin{align*}
A & \xrightarrow{K} B \xrightarrow{R} C \\
\downarrow \psi & \quad \downarrow \nu \\
A & \xrightarrow{F} C \\
\end{align*}
\]

with the property that every $n + 1$-ary cell of the form displayed below-left factors uniquely through $\nu: K \times R \Rightarrow F$ as below-right:

\[
\begin{align*}
A & \xrightarrow{K} B \xrightarrow{E_1} \cdots \xrightarrow{E_n} C \\
\downarrow & \quad \downarrow \exists \\
A & \xrightarrow{F} C \\
\end{align*}
\]
Dually, a right lifting of $A \overset{F}{\to} C$ through $B \overset{H}{\to} C$ consists of a pair given by a module $A \overset{L}{\to} B$ together with a binary cell

\[
\begin{array}{c}
A \xymatrix{ \ar[r]^L & B \ar[r]^H & C } \\
A \ar@{.>}[r]_F & C
\end{array}
\]

with the property that every $n+1$-ary cell of the form displayed below-left factors uniquely through $\lambda: L \times H \Rightarrow F$ as below-right:

\[
\begin{array}{c}
A \xymatrix{ E_1 \ar[r] & \cdots \ar[r] & B \ar[r]^H & C } \\
A \ar@{.>}[r]_F & C
\end{array}
\qquad =
\begin{array}{c}
A \xymatrix{ E_1 \ar[r] & \cdots \ar[r] & B \ar[r]^H & C } \\
A \ar@{.>}[r]_L & B \ar[r]^H & C \\
A \ar@{.>}[r]_F & C
\end{array}
\]

Because of the asymmetry in Definition 8.1.10, there is no corresponding notion of left extension or left lifting. It follows easily from these definitions that right extensions or right liftings are unique up to vertical isomorphism in $\mathbf{Mod}(K)$; see Exercise 9.1.i.

9.1.3. LEMMA. For any functor $f: A \to B$, there is a binary cell

\[
\begin{array}{c}
\xymatrix{ B \ar[r]^\text{Hom}_B(f,B) & A \ar[r]^\text{Hom}_B(B,f) & B } \\
B \ar@{.>}[r]_\epsilon & B
\end{array}
\]

that defines both a right extension of $B \overset{\text{Hom}_B}{\to} B$ through $B \overset{\text{Hom}_B(f,B)}{\to} A$ and a right lifting of $B \overset{\text{Hom}_B}{\to} B$ through $A \overset{\text{Hom}_B(B,f)}{\to} B$.

Proof. The binary cell $\epsilon: \text{Hom}_B(f,B) \times \text{Hom}_B(B,f) \Rightarrow \text{Hom}_B$, which also appears as a counit of sorts in Exercise 8.4.v, corresponds to the unary unit cell $\text{Hom}_f$ under the bijections of Theorem 8.4.4 and Proposition 8.2.4. The verification of the universal properties is left as Exercise 9.1.ii. □

The result of Lemma 9.1.3 is a special case of a more general family of examples:

9.1.4. LEMMA. For any module $A \overset{E}{\to} B$ and any pair of functors $g: C \to A$ and $f: D \to B$ the canonical cells

\[
\begin{array}{c}
A \xymatrix{ \ar[r]^{\text{Hom}_A(g,A)} & C \ar[r]^{E(1,g)} & B } \\
A \ar@{.>}[r]_\rho & B
\end{array}
\quad \quad \quad \quad \quad
\begin{array}{c}
A \xymatrix{ \ar[r]^{\text{Hom}_B(B,f)} & D \ar[r]^{E(f,1)} & B } \\
A \ar@{.>}[r]_\rho & B
\end{array}
\]

exhibit $E(1,g)$ as the right extension of $E$ through $\text{Hom}_A(g, A)$ and exhibit $E(f,1)$ as the right lifting of $E$ through $\text{Hom}_B(B, f)$.
PROOF. The canonical cells of the statement arise from applying the bijection of Theorem 8.4.4 to the restriction cells of Proposition 8.2.1, which is to say that in the case of the right extension diagram above-left this cell is obtained as the composite

\[
\begin{array}{c}
A \\ \downarrow \rho \\
\text{Hom}_A(g, A) \\
A \\ \downarrow \rho \\
\end{array}
\xrightarrow{E(1, g)}
\begin{array}{c}
C \\ \downarrow \\
\text{Hom}_A(g, A) \\
C \\ \downarrow \\
\end{array}
\xrightarrow{g}
\begin{array}{c}
B \\ \downarrow \\
\text{Hom}_A(g, A) \\
B \\ \downarrow \\
\end{array}
\xrightarrow{E(1, g)}
\begin{array}{c}
E \\
\downarrow \\
E \\
\end{array}
\]

The universal property of the right extension is provided by Corollary 8.4.6. \qed

In particular:

9.1.5. COROLLARY. Any module \( A \overset{E}{\to} B \) is the right extension of itself along \( A \overset{\text{Hom}_A}{\to} A \) as well as the right lifting of itself through \( B \overset{\text{Hom}_B}{\to} B \). \boxed{□}

Right extensions and right liftings can be understood as right adjoints to horizontal composition with a module on the left or on the right, respectively. This leads to the following “associativity” result, which we formulate for right extensions, leaving the dual result for right liftings to the reader.

9.1.6. PROPOSITION. Suppose \( A \overset{K}{\to} B \), \( B \overset{H}{\to} C \), and \( A \overset{E}{\to} D \) are modules so that the composite \( K \otimes H \) and right extension \( B \overset{R_KF}{\to} D \) modules exist. Then the right extension of \( R_KF \) along \( H \) exists if and only if the right extension of \( F \) along \( K \otimes H \) exists, in which case \( R_H(R_KF) \simeq_{C \times D} R_{K \otimes H}F \).

PROOF. The universal property of the binary composite cell \( \mu : K \times H \Rightarrow K \otimes H \) and right extension cell \( \nu : K \times R_KF \Rightarrow F \) provide a bijection between cells involving an arbitrary compatible sequence of modules \( R_1 \times \cdots \times R_n \) from \( C \) to \( D \)

\[
\begin{array}{c}
A \\
\downarrow \mu \\
K \otimes H \\
A \\
\downarrow \nu \\
F \\
\end{array}
\xrightarrow{R_1 \times \cdots \times R_n}
\begin{array}{c}
B \\
\downarrow \\
C \\
\downarrow \\
D \\
\end{array}
\xrightarrow{R_KF}
\begin{array}{c}
C \\
\downarrow \\
D \\
\end{array}
\]

In the case of an empty sequence of modules, this bijection encodes an adjointness between fibered module maps \( K \otimes H \Rightarrow F \) and fibered module maps \( H \Rightarrow R_KF \).

If the right extension \( R_{K \otimes H}F \) exists we take this for \( R \) and use the binary cell on the lower-left to induce the binary cell on the upper-right, which can be shown to exhibit \( R_{K \otimes H}F \) as the right extension \( R_{H}(R_KF) \) of \( R_KF \) along \( H \). Conversely, if the right extension \( R_{H}(R_KF) \) exists we use the binary cell on the upper-right to induce the binary cell on the lower-left, which can be shown to exhibit \( R_{H}(R_KF) \) as the right extension \( R_{K \otimes H}F \) of \( F \) along \( K \otimes H \). This transference of universal properties is straightforward, following again from the bijection just exhibited.
Finally, if separately the right extensions $R_H(R_K F)$ and $R_{K \otimes H} F$ are known to exist, then the argument given above combined with the uniqueness of right extensions combines to show that $R_{K \otimes H} F \simeq R_H(R_K F)$ as modules from $C$ to $D$; see Exercise 9.1.i.

We now explain how Definition 9.1.2 relates to Definition 9.1.1 via the covariant and contravariant embeddings of Definition 8.4.12.

9.1.7. **Lemma.** If

\[
\begin{array}{ccc}
A & \longrightarrow & B \\
\downarrow \downarrow & & \downarrow \downarrow \\
A & \longrightarrow & C \\
\end{array}
\]

\[
\downarrow \downarrow \nu_*
\]

defines a right extension in the virtual equipment of modules, then $\nu: rk \Rightarrow f$ defines a right extension in the homotopy 2-category. Dually if

\[
\begin{array}{ccc}
A & \longrightarrow & B \\
\downarrow \downarrow & & \downarrow \downarrow \\
A & \longrightarrow & C \\
\end{array}
\]

\[
\downarrow \downarrow \lambda^*
\]

defines a right lifting in the virtual equipment of modules, then $\lambda: g \Rightarrow \ell h$ is a left extension in the homotopy 2-category.

**Proof.** By Corollary 8.4.9 binary cells $\nu_*: \text{Hom}_B(B, k) \times \text{Hom}_C(C, r) \Rightarrow \text{Hom}_C(C, f)$ correspond to unary cells $\nu_*: \text{Hom}_C(C, rk) \Rightarrow \text{Hom}_C(C, f)$, which by Proposition 8.4.11 correspond to natural transformations $\nu: rk \Rightarrow f$ in the homotopy 2-category. Under this correspondence the universal property of Definition 9.1.2 clearly subsumes that of Definition 9.1.1 by restricting to right-represented modules. The left extension case is similar, via the contravariant embedding of Definition 8.4.12. □

A sharper characterization of the right extension diagrams of modules in the image of the covariant embedding will have to wait for Theorem 9.3.3, but we can characterize the right lifting diagrams of modules in the image of the covariant embedding now.

Recall the notion of absolute right lifting diagram introduced in Definition 2.3.4.

9.1.8. **Proposition.** A 2-cell in the homotopy 2-category of an $\infty$-cosmos as below-left defines an absolute right lifting diagram if and only if the corresponding binary cell displayed below-right defines a right lifting in the virtual equipment of modules:

\[
\begin{array}{ccc}
C & \longrightarrow & B \\
\downarrow \downarrow \rho & & \downarrow \downarrow \\
C & \longrightarrow & A \\
\end{array}
\]

\[
\downarrow \downarrow \rho_*
\]

\[
\begin{array}{ccc}
\text{Hom}_B(B, r) & \longrightarrow & \text{Hom}_A(A, f) \\
\downarrow \downarrow & & \downarrow \downarrow \\
\text{Hom}_A(A, g) & \longrightarrow & A \\
\end{array}
\]

Dually, a 2-cell in the homotopy 2-category of an $\infty$-cosmos as below-left defines an absolute left lifting diagram if and only if the corresponding binary cell displayed below-right defines a right extension in the virtual equipment.
PROOF. By Proposition 8.4.11, natural transformations in the homotopy 2-category of an ∞-cosmos correspond bijectively to unary squares in the virtual equipment of modules of various forms. By this result, Corollary 8.4.6, and Corollary 8.4.9, there are canonical bijections:

\[
\begin{array}{ccc}
\text{Hom}(A,b) & \overset{\Psi}{\leftrightarrow} & \text{Hom}(A,\ell) \\
\text{Hom}(A,c) & \overset{\Psi}{\leftrightarrow} & \text{Hom}(A,\ell)
\end{array}
\]

If the binary cell \(\rho^* : \text{Hom}(B,r) \times \text{Hom}(A,f) \Rightarrow \text{Hom}(A,g)\) defines a right lifting diagram in the virtual equipment of modules, then there is a unique factorization

\[
\begin{array}{c}
\text{Hom}(A,f) \\
\text{Hom}(A,g)
\end{array}
\]

Reversing the canonical bijection (9.1.9), this defines the desired unique factorization

\[
\begin{array}{ccc}
\text{Hom}(A,f) & \overset{\Psi}{\leftrightarrow} & \text{Hom}(A,g) \\
\text{Hom}(A,f)
\end{array}
\]

in the homotopy 2-category. Thus if \(\rho^* : \text{Hom}(B,r) \times \text{Hom}(A,f) \Rightarrow \text{Hom}(A,g)\) is a right lifting, then \(\rho^* : f \Rightarrow g\) is an absolute right lifting.

Conversely, suppose \(\rho^* : f \Rightarrow g\) is an absolute right lifting and consider a cell in the virtual equipment of modules of the following form:

\[
\begin{array}{c}
\text{Hom}(A,f) \\
\text{Hom}(A,g)
\end{array}
\]

Let \(C \overset{\rho}{\leftrightarrow} E \overset{\mu}{\Rightarrow} B\) denote the composite two-sided fibration \(E_1 \times \cdots \times E_n\). By Remark 8.3.12 applied to \(C \overset{q}{\leftrightarrow} E \overset{p}{\Rightarrow} B\), module maps \(\Psi : E_1 \times \cdots \times E_n \times \text{Hom}(A,f) \Rightarrow \text{Hom}(A,g)\) stand in bijection with
module maps \( \hat{\psi} : \Hom_C(q, C) \times \Hom_B(B, p) \times \Hom_A(A, f) \Rightarrow \Hom_A(A, g) \), as displayed below-left. As argued in (9.1.9), these stand in canonical bijection with natural transformations as below-center:

\[
\begin{array}{c}
\begin{array}{ccc}
C & \longrightarrow & E \\
\| & & \| \\
C & \longrightarrow & \Hom_A(A, g)
\end{array}
\end{array}
\quad \leftrightarrow \quad
\begin{array}{c}
\begin{array}{ccc}
q & \xrightarrow{\hat{\psi}} & E \\
\| & & \| \\
C & \longrightarrow & B
\end{array}
\end{array}
\quad \leftrightarrow \quad
\begin{array}{c}
\begin{array}{ccc}
q & \xrightarrow{\psi} & p \\
\| & & \| \\
C & \longrightarrow & A
\end{array}
\end{array}
\quad \Rightarrow \quad
\begin{array}{c}
\begin{array}{ccc}
E & \longrightarrow & A \\
\| & & \| \\
C & \longrightarrow & B
\end{array}
\end{array}
\]

Since \( \hat{\rho} : fr \Rightarrow g \) is assumed to be an absolute right lifting, \( \psi \) factors uniquely through \( \hat{\rho} \) to define a corresponding 2-cell \( \xi : p \Rightarrow rq \) as above-right. Applying (9.1.9) again, this constructs a unique factorization in the virtual equipment of modules:

\[
\begin{array}{c}
\begin{array}{ccc}
C & \longrightarrow & E_1 \longrightarrow \cdots \longrightarrow E_n \longrightarrow \Hom_A(A, f) \\
\| & & \| \\
C & \longrightarrow & \Hom_A(A, g)
\end{array}
\end{array}
\quad = \quad
\begin{array}{c}
\begin{array}{ccc}
C & \longrightarrow & E_1 \longrightarrow \cdots \longrightarrow E_n \longrightarrow \Hom_A(A, f) \\
\| & & \| \\
C & \longrightarrow & \Hom_B(B, r) \longrightarrow \Hom_A(A, f) \longrightarrow \Hom_A(A, g)
\end{array}
\end{array}
\]

Thus if \( \hat{\rho} : fr \Rightarrow g \) is an absolute right lifting, then \( \hat{\rho} \) is a right lifting.

In Theorem 9.3.3 we will discover that right extensions of modules in the image of the covariant embedding are precisely characterized by the sought-for pointwise right extensions in the homotopy 2-category; dually pointwise left extensions correspond to right liftings of modules in the image of the contravariant embedding. In the next section, we build towards the 2-categorical definition of this notion.

**Exercises.**

9.1.i. **Exercise.** Suppose \( B \xrightarrow{R} C \) and \( B \xrightarrow{S} C \) both define right extensions of a module \( A \xrightarrow{F} C \) along a module \( A \xrightarrow{K} B \) in the sense of Definition 9.1.2. Prove that \( R \simeq_{B \times C} S \).

9.1.ii. **Exercise.** Complete the proof of Lemma 9.1.3 without appealing to Lemma 9.1.4.

9.1.iii. **Exercise.** A virtual equipment is **closed** if the right extensions and right liftings of Definition 9.1.2 always exist. In a closed virtual equipment, prove that a cell \( \mu : E_1 \times \cdots \times E_n \Rightarrow \hat{E} \) is a composite
if and only if restriction along $\mu$ defines a bijection between fibered unary cells $E \Rightarrow F$ and fibered cells $E_1 \times \cdots \times E_n \Rightarrow F$ for all modules $F$ that are parallel to $E$.

9.1.iv. Exercise. Dualize Proposition 9.1.6 to characterize right liftings through a composite of two modules.

9.1.v. Exercise. Verify the dual statement of Proposition 9.1.8, that absolute left lifting diagrams $\lambda : g \Rightarrow f \ell$ correspond to right extension diagrams $\lambda^* : \text{Hom}_A(f, A) \times \text{Hom}_B(\ell, B) \Rightarrow \text{Hom}_A(g, A)$.

9.2. Exact Squares

To motivate the main definition of this section, let us try to guess the universal property of a pointwise right extension in an $\infty$-cosmos by considering a special case that we already understand. If the ambient $\infty$-cosmos is cartesian closed, then the pointwise right extension of a diagram $f : A \rightarrow C$ along a functor $k : A \rightarrow B$ is intended to define the value of a right adjoint, which may or may not exist in toto, to the restriction functor $\text{res}_k : C^B \rightarrow C^A$ at the element $f : 1 \rightarrow C^A$. In the case of extensions along a functor $! : A \rightarrow 1$, the restriction functor is the constant diagram functor $\Delta : C \rightarrow C^A$ considered in Definition 2.3.2, and so via Definition 2.3.7 we can understand the pointwise right extension as computing the limit of $f$. The following lemma describes the transposed form of this universal property.

9.2.1. Lemma. In a cartesian closed $\infty$-cosmos, the triangle below-left is an absolute right lifting diagram — defining the limit element and limit cone of $f$ — if and only if the transposed triangle below-center has the property that for any $\infty$-category $X$, the composite diagram below-right is a right extension diagram.

**Proof.** A factorization of a cone with summit $X$ through the absolute right lifting of $f$ along the constant diagram functor

transposes to a factorization as below:

Lemma 9.2.1 reveals that to define the limit of $f : A \rightarrow C$ in an $\infty$-cosmos that is not necessarily cartesian closed, it is not enough to form the right extension of $! : A \rightarrow 1$. In terminology we will
introduce in Definition 9.3.1 below, we must ask in addition that the right extension diagram is stable under pasting with squares of the form:

\[
\begin{array}{ccc}
X \times A & \xrightarrow{\pi} & A \\
\downarrow & & \downarrow \\
X & \xrightarrow{!} & 1
\end{array}
\]

How might we characterize such squares? Firstly, they are pullbacks each of whose legs is a bifibration. Secondly, they are comma squares, where the comma cone is an identity 2-cell best regarded as pointing in a direction compatible with \( \nu \) in the statement of Lemma 9.2.1. By Lemmas 9.2.6 and 9.2.7, we shall see that both of these are instances of exact squares, which we now introduce.

By Proposition 8.4.11, natural transformations in the homotopy 2-category of an \( \infty \)-cosmos correspond bijectively to unary squares in the virtual equipment of modules of various forms, and in particular, this result, Theorem 8.4.4, Proposition 8.2.4, and Proposition 8.2.1 defines a canonical bijection:

\[
\text{Hom}_C(k, C) \times \text{Hom}_B(B, h) \leftrightarrow \text{Hom}_A(f, g)
\]

9.2.2. Definition (exact squares). A square in the homotopy 2-category of an \( \infty \)-cosmos

\[
\begin{array}{ccc}
C & \xrightarrow{\alpha} & B \\
\downarrow & & \downarrow \\
A & \xleftarrow{f} & D
\end{array}
\]

is exact\(^1\) if and only if the corresponding cell below-left, which under the bijection of Lemma 8.1.18 encodes the below-right pasted composite

\[
\begin{array}{ccc}
C & \xrightarrow{\alpha} & B \\
\downarrow & & \downarrow \\
A & \xleftarrow{f} & D
\end{array}
\leftrightarrow
\begin{array}{ccc}
\text{Hom}_C(k, C) & \xrightarrow{h} & \text{Hom}_B(B, h) \\
\downarrow & & \downarrow \\
\text{Hom}_A(f, g) & \xleftarrow{\phi} & \text{Hom}_C(k, C) \times \text{Hom}_B(B, h)
\end{array}
\]

\[
(9.2.3)
\]

displays \( \text{Hom}_A(f, g) \) as the composite \( \text{Hom}_C(k, C) \otimes \text{Hom}_B(B, h) \) as defined in Definition 8.3.1.

\(^1\)Unfortunately the terminology “exact square” is used in a variety of different settings. We hope that the context will make it clear that the present notion has nothing to do with squares that are both pushouts and pullbacks in a stable \( \infty \)-category.
When the boundary square is clear from context, for economy of language we may write that “\( \alpha : fh \Rightarrow gk \) is an exact square” but note that the meaning of the exactness condition is changed if the positions of any of the four boundary arrows of the square inhabited by the 2-cell \( \alpha \) are shifted.²

9.2.4. REMARK (exactness as a Beck-Chevalley condition). By Corollary 8.4.8, the cell \( \mu : \text{Hom}_A(A, g) \times \text{Hom}_A(f, A) \Rightarrow \text{Hom}_A(f, g) \) encoded by the map of spans defined by 1-cell induction

![Diagram](image)

is a composite. Exactness says that \( \alpha \) induces an isomorphism

\[
\hat{\alpha} : \text{Hom}_{C}(k, C) \otimes \text{Hom}_{B}(B, h) \cong \text{Hom}_A(A, g) \otimes \text{Hom}_A(f, A)
\]

of modules from \( C \) to \( B \).

9.2.5. DIGRESSION (strong exactness). Recall from §8.3 that many of the formally-defined composite cells that exist in any virtual equipment, are in fact strong composites in the virtual equipment of modules associated to an \( \infty \)-cosmos. Based on this experience, one might expect that many of the exact squares we will encounter in the virtual equipment of modules are in fact strongly exact, meaning that the cell \( \hat{\alpha} : \text{Hom}_{C}(k, C) \times \text{Hom}_{B}(B, h) \Rightarrow \text{Hom}_A(f, g) \) is a strong composite, and indeed this is the case. In fact, in \( \infty \)-cosmoi of \((\infty, 1)\)-categories all composites exist and are strong: the tensor product of modules can be defined by a fiberwise coinverter construction that is stable under pullback. Since the composite of any compatible sequence of modules is equivalent to the strong composite, in such \( \infty \)-cosmoi, all composites, and hence all exact squares, automatically satisfy the stronger universal property.

The primary role played by exact squares here is in developing the notion of pointwise left and right extensions, and for this the weaker 2-categorical universal property suffices. We note in passing that our formally-defined exact squares are strong, but typically only appeal to the weaker exactness property in proofs. There is one instance when a stronger notion of exactness may be preferable, which we discuss in Remark 9.5.6.

The remainder of this section is devoted to examples of exact squares.

9.2.6. LEMMA (comma squares are exact). For any cospan \( C \xrightarrow{g} A \xleftarrow{f} B \), the comma cone defines a strongly exact square:

![Diagram](image)

²For instance, compare the statements of Lemmas 9.2.8 and 9.4.4.
Proof. By Proposition 8.3.11, the module $C^\mathrm{Hom}(f, g) \hookrightarrow B$ is the strong composite of the left representation of its left leg followed by the right representation of its right leg: $\mathrm{Hom}_C(p_1, C) \otimes \mathrm{Hom}_B(B, p_0) \cong \mathrm{Hom}_A(f, g)$, and by Remark 8.3.13, the binary composition cell $\mathrm{Hom}_C(p_1, C) \times \mathrm{Hom}_B(B, p_0) \Rightarrow \mathrm{Hom}_A(f, g)$ corresponds under the bijection of Lemma 8.1.18 to the pasted composite

\[
\begin{array}{c}
\mathrm{Hom}_C(p_1, C) \times \mathrm{Hom}_B(B, p_0) \\
\mathrm{Hom}_C(p_1, C) \Rightarrow \mathrm{Hom}_B(B, p_0) \\
\mathrm{Hom}_A(f, g) \Rightarrow \mathrm{Hom}_A(f, g) \\
C \Rightarrow B \\
\xymatrix{C \ar[r]^-f & A} \\
\end{array}
\]

This recovers the cell $\phi$ defined by (9.2.3) that tests the exactness of comma square $\phi : fp_0 \Rightarrow gp_1$. □

9.2.7. Lemma. If $g : C \to A$ is a cartesian fibration or $f : B \to A$ is a cocartesian fibration, then the pullback square

\[
\begin{array}{c}
P \\
\xymatrix{C \ar[r] & B} \\
\end{array}
\]

is strongly exact.

Proof. The two statements are dual though the positions of the cocartesian and cartesian fibrations cannot be interchanged, as the proof will reveal. If $f : B \Rightarrow A$ is a cocartesian fibration in an $\infty$-cosmos $\mathcal{K}$, observe that the functor $\lbrack \text{id} \rbrack : P \to \mathrm{Hom}_A(f, A)$ induced by the identity 2-cell $f \pi_0 = g \pi_1$ is a pullback of the functor $\lbrack \text{id}_f \rbrack : B \to \mathrm{Hom}_A(f, A)$ induced by the identity 2-cell $\text{id}_f$.

Since $f$ is a cocartesian fibration, Theorem 5.2.10(ii) tells us that $\lbrack \text{id}_f \rbrack : B \to \mathrm{Hom}_A(f, A)$ has a fibered left adjoint over $A$. This fibered adjunction pulls back via the cosmological functor $g^* : \mathcal{K}_{/A} \to \mathcal{K}_{/C}$ to define a fibered left adjoint to $\lbrack \text{id} \rbrack : P \to \mathrm{Hom}_A(f, g)$. 

301
Since \( \pi_0 = p_0^\ast \text{id} \), Corollary 8.4.9 implies that the canonical cell
\[
\text{Hom}_\text{p}(\pi_0, \text{id}) \times \text{Hom}_B(B, p_0) \Rightarrow \text{Hom}_B(B, \pi_0)
\]
is a strong composite. Since \( \ell \dashv \text{id} \), \( \text{Hom}(\ell, P) \simeq \text{Hom}_A(f, g) \times \text{id} \) by Proposition 4.1.1. And since \( p_1 = \pi_1 \ell \), Corollary 8.4.9 again implies that the canonical cell
\[
\text{Hom}_C(p_1, C) \times \text{Hom}_P(\ell, P) \Rightarrow \text{Hom}_C(p_1, C)
\]
is a strong composite. Composing these bijections, we see that cells with domain \( \text{Hom}_C(p_1, C) \times \text{Hom}_P(\ell, P) \Rightarrow \text{Hom}_A(f, g) \) and \( \hat{\phi} : \text{Hom}_C(p_1, C) \times \text{Hom}_B(B, p_0) \Rightarrow \text{Hom}_A(f, g) \) correspond under the bijection just described. Since Lemma 9.2.6 proves that \( \hat{\phi} \) is a strong composite, by Lemma 8.3.8 so is \( \text{id} \).

For later use, we observe some trivial examples of exact squares:

9.2.8. **Lemma.** For any functor \( k : A \to B \), the identity cells define strongly exact squares.

**Proof.** Exercise 9.2.i.

More generally:

9.2.9. **Lemma.** For any pair of functors \( f : A \to B \) and \( g : C \to D \) the square
\[
\begin{array}{ccc}
A \times C & \xrightarrow{f \times C} & B \times C \\
\downarrow{A \times g} & & \downarrow{B \times g} \\
A \times D & \xleftarrow{f \times D} & B \times D
\end{array}
\]
is strongly exact.

**Proof.** Exercise 9.2.ii.

Finally, the plethora of examples of exact squares just established can be composed to yield further exact squares:
Lemma (composites of exact squares). Given a diagram of squares in the homotopy 2-category

![Diagram of squares in the homotopy 2-category](image)

if \( \alpha : fh \Rightarrow gk \), \( \beta : bp \Rightarrow hq \), and \( \gamma : kr \Rightarrow cs \) are all exact squares then so are the composite rectangles \( \alpha q \cdot f \beta \) and \( g \gamma \cdot \alpha r \), and these are strongly exact if the constituent squares are. Consequently, arbitrary “double categorical” composites of (strongly) exact squares define (strongly) exact squares.

**Proof.** The two cases are co-duals, so it suffices to prove that the rectangle \( \alpha q \cdot f \beta : g(kq) \Rightarrow (fb)p \) is exact. The corresponding cell \( \overline{\alpha q} \cdot \overline{f \beta} \) displayed below-left factors as below-right:

![Cell factors diagram](image)

through a cell \( \overline{\alpha} \) defined by the universal property of the composite \( \text{Hom}_B(B,h) \otimes \text{Hom}_B(b,B) \approx \text{Hom}_B(B,h) \) of Proposition 8.4.7 by the pasting equality:

![Pasting equality diagram](image)

By exactness of \( \alpha, \overline{\alpha} \) and both cells named \( \circ \) are composites, so by Lemma 8.3.3 or 8.3.8, \( \overline{\alpha} \) is a composite as well. By exactness of \( \beta \) and Lemma 8.3.3 or 8.3.8 again it now follows that \( \overline{\alpha q} \cdot \overline{f \beta} \) is also a composite, proving exactness of the rectangle \( \alpha q \cdot f \beta : g(kq) \Rightarrow (fb)p \). \( \square \)

**Exercises.**

9.3. Pointwise Right and Left Extensions

In this section, we give four definitions of pointwise right extension and prove they are equivalent. Our proof will reveal that the general 2-categorical notion right extensions given in Definition 9.1.1 is too weak on its own.

9.3.1. Definition (stability of extensions under pasting). A right extension diagram \( \nu: r_k \Rightarrow f \) in a 2-category is said to be \textit{stable under pasting with a square} \( \alpha \)

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow{k} & & \downarrow{r} \\
B & & \\
\end{array}
\quad \quad \quad
\begin{array}{ccc}
D & \xrightarrow{g} & A \\
\downarrow{h} & & \downarrow{k} \\
E & \xleftarrow{b} & B \\
\end{array}
\]

if the pasted composite

\[
\begin{array}{ccc}
D & \xrightarrow{g} & A & \xrightarrow{f} & C \\
\downarrow{h} & & \downarrow{k} & & \downarrow{r} \\
E & \xleftarrow{b} & B & & \\
\end{array}
\]

(9.3.2)

defines a right extension \( rb: E \rightarrow C \) of \( fg: D \rightarrow C \) along \( h: D \rightarrow E \). The co-dual of this statement defines what it means for a left extension diagram to be stable under pasting with a square.

9.3.3. Theorem (pointwise right extensions). For a diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow{k} & & \downarrow{r} \\
B & & \\
\end{array}
\]

in the homotopy 2-category of an \( \infty \)-cosmos \( \mathcal{K} \) the following are equivalent:

(i) \( \nu: r_k \Rightarrow f \) defines a right extension in \( \mathcal{V} \mathcal{K} \) that is stable under pasting with exact squares.

(ii) \( \nu: r_k \Rightarrow f \) defines a right extension in \( \mathcal{V} \mathcal{K} \) that is stable under pasting with comma squares.

(iii) \( \nu_*: \text{Hom}_B(B,k) \times \text{Hom}_C(C,r) \Rightarrow \text{Hom}_C(C,f) \) defines a right extension in \( \text{Mod}(\mathcal{K}) \).

(iv) For any exact square

\[
\begin{array}{ccc}
A & \xrightarrow{g} & D \\
\downarrow{k} & & \downarrow{h} \\
B & & \xleftarrow{b} E \\
\end{array}
\]

\( (\nu g \cdot r\alpha)_*: \text{Hom}_E(E,h) \times \text{Hom}_C(C,rb) \Rightarrow \text{Hom}_C(C,fg) \) defines a right extension in \( \text{Mod}(\mathcal{K}) \).

When these conditions hold, we say \( r: B \rightarrow C \) defines a \textit{pointwise right extension} of \( f: A \rightarrow C \) along \( k: A \rightarrow B \).

\textbf{Proof.} Lemma 9.2.6 proves (i) \( \Rightarrow \) (ii).
To show (ii)⇒(iii), suppose \( \nu : rk \Rightarrow f \) defines a right extension in \( \mathbb{K} \) that is stable under pasting with comma squares and consider a cell in \( \text{Mod}(\mathbb{K}) \):

\[
\begin{array}{cccccc}
A & \longrightarrow & B & \longrightarrow & \cdots & \longrightarrow & C \\
| & | & \downarrow & | & | & | & | \\
A & \longrightarrow & \text{Hom}_C(C, f) & & & & C
\end{array}
\]

Let \( B \leftarrow E \rightarrow C \) denote the composite two-sided fibration \( E_1 \times \cdots \times E_n \). By Remark 8.3.12, module maps \( \text{Hom}_B(B, k) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, f) \) stand in bijection with module maps \( \text{Hom}_B(B, k) \times \text{Hom}_B(q, B) \times \text{Hom}_C(C, p) \Rightarrow \text{Hom}_C(C, f) \). By Corollary 8.4.6 and Proposition 8.4.7, such module maps stand in bijection with module maps \( \text{Hom}_B(q, k) \Rightarrow \text{Hom}_C(p, f) \). By Lemma 8.1.18, these module maps correspond bijectively to 2-cells

\[
\begin{array}{ccc}
\text{Hom}_B(q, k) & \longrightarrow & \text{Hom}_B(q, k) \\
p_1 & \downarrow & p_0 \\
A & \longrightarrow & E \\
f & \searrow & \swarrow p \\
& C & \leftarrow \text{Hom}_C(C, p)
\end{array}
\]

in the homotopy 2-category. By the hypothesis (ii),

\[
\begin{array}{ccc}
\text{Hom}_B(q, k) & \longrightarrow & \text{Hom}_B(q, k) \\
p_1 & \downarrow & p_0 \\
A & \longrightarrow & A \\
f & \searrow & \swarrow \gamma \\
& C & \leftarrow \text{Hom}_C(C, p) \\
\end{array}
\]

defines a right extension in \( \mathbb{K} \), so \( \alpha \) factors uniquely through this pasted composite via a natural transformation \( \gamma : p \Rightarrow rq \). By Proposition 8.4.11, this defines a cell \( \gamma_* : \text{Hom}_C(C, p) \Rightarrow \text{Hom}_C(C, rq) \), which by Corollary 8.4.6 gives rise to a canonical cell \( \hat{\gamma} : \text{Hom}_B(q, B) \times \text{Hom}_C(C, p) \Rightarrow \text{Hom}_C(C, r) \). By Remark 8.3.12 again, this produces the desired unique factorization

\[
\begin{array}{ccc}
A & \longrightarrow & B & \longrightarrow & \cdots & \longrightarrow & C \\
| & | & \downarrow & | & | & | & | \\
A & \longrightarrow & \text{Hom}_C(C, f) & & & & C
\end{array}
\]

To show (iii)⇒(iv), consider a diagram (9.3.2) in which \( \alpha : bh \Rightarrow kg \) is exact and \( \nu_* : \text{Hom}_B(B, k) \times \text{Hom}_C(C, r) \Rightarrow \text{Hom}_C(C, f) \) defines a right extension diagram in \( \text{Mod}(\mathbb{K}) \). Now by Corollary 8.4.6, a cell

\( \text{Hom}_E(E, h) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, fg) \)

corresponds to a cell

\( \text{Hom}_A(g, A) \times \text{Hom}_E(E, h) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, f) \).
By exactness of $\alpha$, this corresponds to a cell

$$\text{Hom}_B(b, k) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, f),$$

or equivalently, upon restricting along the composite map $\text{Hom}_B(B, k) \times \text{Hom}_B(b, B) \Rightarrow \text{Hom}_B(b, k)$ to a cell

$$\text{Hom}_B(B, k) \times \text{Hom}_B(b, B) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, f).$$

Since $B \Rightarrow C$ is the right extension of $A \Rightarrow C$ along $A \Rightarrow B$, this corresponds to a cell

$$\text{Hom}_B(b, B) \times E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, r),$$

which transposes via Corollary 8.4.6 to a cell

$$E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_C(C, rb),$$

which gives the factorization required to prove that the module $E \Rightarrow \text{Hom}_C(C, rb)$ is the right extension of $D \Rightarrow \text{Hom}_C(C, r)$ and trace back up through the bijection just described.

Using Lemma 8.1.18 this is straightforward.

Finally Lemma 9.1.7 and the trivial example of Lemma 9.2.8 prove that $(iv) \Rightarrow (i)$.  

Using the various characterizations of Theorem 9.3.3, we can establish some basic stability properties of pointwise right extensions.

9.3.4. COROLLARY. The pasted composite (9.3.2) of a pointwise right extension with an exact square is a pointwise right extension.

PROOF. Lemma 9.2.10, the pasted composite of two exact squares remains an exact square, so by Theorem 9.3.3(i), the pasted composite of a pointwise right extension remains stable under pasting with exact squares.

9.3.5. COROLLARY. Consider a diagram of functors and natural transformations

$$\begin{array}{ccc}
A & \xrightarrow{f} & D \\
\downarrow k \hspace{1cm} & & \hspace{1cm} \downarrow s \\
B & \xrightarrow{r} & C \\
\downarrow h \\
C
\end{array}$$

where $(r, v : rk \Rightarrow f)$ is a pointwise right extension of $f$ along $k$. Then $(s, \sigma : sh \Rightarrow r)$ is a pointwise right extension of $r$ along $h$ if and only if $(s, v \cdot \sigma k : shk \Rightarrow f)$ is a pointwise right extension of $f$ along $hk$.

PROOF. By Theorem 9.3.3, a natural transformation in the homotopy 2-category is a pointwise right extension if and only if its covariant embedding into the virtual equipment of modules is a right extension. The binary module maps $\sigma_* : \text{Hom}_C(C, h) \times \text{Hom}_D(D, s) \Rightarrow \text{Hom}_D(D, r)$ and
Thus, by that result, $\sigma_\ast$ is a right extension if and only if $(\nu \cdot \sigma_k)_\ast$ is a right extension, as claimed. □

Exercises.

9.3.i. Exercise. Using Lemma 9.1.7 as a hint, state and prove a dual version of Theorem 9.3.3 defining pointwise left extensions in the homotopy 2-category of an $\infty$-cosmos.

9.4. Formal Category Theory in a Virtual Equipment

One reason for our interest in the virtual equipment of modules is that it captures their calculus within an $\infty$-cosmos. A stronger motivation is the theorems about $\infty$-category theory that can be proven within a virtual equipment. In this section, we revisit adjunctions and fully faithful functors from a module-theoretic point of view. In the next sections, we bring (co)limits and weighted (co)limits into consideration.

9.4.1. Proposition. For any pair of functors $f : B \to A$ and $u : A \to B$ in an $\infty$-cosmos $\mathcal{K}$ the following are equivalent:

(i) The natural transformation $\epsilon : fu \Rightarrow id_A$ is the counit of an adjunction $f \dashv u$.

(ii) The unary cell representing the map $\epsilon \cdot f(\_): \text{Hom}_B(B, u) \to \text{Hom}_A(f, A)$

\[ A \xrightarrow{\epsilon} B \]
\[ A \xrightarrow{u} B \]
\[ A \xrightarrow{\text{Hom}_A(f, A)} B \]

defines a vertical isomorphism in $\text{Mod}(\mathcal{K})$.

(iii) The square

\[ A \xrightarrow{\epsilon} B \]
\[ A \xrightarrow{u} B \]
\[ A \xrightarrow{\epsilon} B \]

is exact.

(iv) There is a pointwise right extension diagram in $\text{Hom}(\mathcal{K})$

\[ A \xrightarrow{\eta \epsilon} A \]
\[ B \xrightarrow{f} \]

(9.4.2)
that is absolute, preserved by any functor \( h: A \rightarrow C \).

**Proof.** The equivalence (i)⇔(ii) is proven by Proposition 4.1.1, via Lemma 8.1.19. To say that \( \varepsilon: fu \Rightarrow \text{id}_A \) is exact is to say that the binary cell below-left is a composite:

\[
\begin{array}{c}
A \xrightarrow{\text{Hom}_A(f,A)} B \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(f,A)} B
\end{array}
\leftrightarrow
\begin{array}{c}
A \xrightarrow{\text{Hom}_B(B,u)} B \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(f,A)} B
\end{array}
\]

By Lemmas 8.3.9(i) and Lemma 8.3.3, this is the case if and only if the unary cell above-right is a composite, and by Lemma 8.3.9(ii) this is exactly the assertion made in (ii). Thus (ii)⇔(iii).

To prove that (ii)⇔(iv), we must show that the binary cell displayed below-left defines a right extension diagram in the virtual equipment of modules.

\[
\begin{array}{c}
A \xrightarrow{\text{Hom}_B(B,u)} B \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(f,A)} C \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(f,A)} C
\end{array}
\cong
\begin{array}{c}
A \xrightarrow{\text{Hom}_A(A,hf)} C \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(A,hf)} C \\
\| \| \| \| \\
\| \| \| \| \\
A \xrightarrow{\text{Hom}_A(A,hf)} C
\end{array}
\]

By (ii), this binary cell is isomorphic to a binary cell of the form displayed above-center. Indeed, Lemma 8.1.18 and Remark 8.3.13 can be used to check that the cell defined above-right composites with the vertical isomorphism \( \varepsilon(f(-)) \): \( \text{Hom}_B(B,u) \cong \text{Hom}_A(f,A) \) to yield the binary cell above-left. This is why we used the notation \( \varepsilon \) for the binary cell in Lemma 9.1.3. Thus, by Lemma 9.1.4, these binary cells are right extensions in the virtual equipment of modules, so we see that (ii)⇔(iv).

The proof that (iv)⇒(i) can be given entirely in the homotopy 2-category and does not require the adjective “pointwise.” Indeed, this is the op-dual of the part of Lemma 2.3.6 left as Exercise 2.3.iii, whose proof works in any 2-category and in particular in \( \mathcal{K}^{op} \).

□

It follows that right extensions along right adjoints and left extensions along left adjoints are easy to calculate:

9.4.3. **Corollary.** The pointwise right extension of any functor along a right adjoint \( u: A \rightarrow B \) is given by its restriction along the left adjoint \( f: B \rightarrow A \), while the pointwise left extension of any functor along a left adjoint is given by its restriction along the right adjoint:

\[
\begin{array}{c}
A \xrightarrow{h} C \\
\| \| \| \| \\
\| \| \| \| \\
B \xrightarrow{\text{ran}_uhhf} C
\end{array}
\]

\[
\begin{array}{c}
A \xrightarrow{hf} C \\
\| \| \| \| \\
\| \| \| \| \\
B \xrightarrow{\text{ran}_fguf} C
\end{array}
\]
Proof. To say in Proposition 9.4.1 that the counit \( \epsilon \) of an adjunction \( f \dashv u \) is an absolute pointwise right extension means that for any functor \( h: A \to C \) the diagram

\[
\begin{array}{ccc}
A & \xrightarrow{\epsilon} & A \\
\downarrow_{u} & & \downarrow_{h} \\
B & \xrightarrow{f} & C
\end{array}
\]

is a pointwise right extension. In particular, \( hf \cong \text{ran}_u h \).

\[
\square
\]

Corollary 3.5.6 describes a number of equivalent characterizations of fully faithful functors between \( \infty \)-categories, including one characterization that was implicitly module-theoretic: a functor \( k: A \to B \) is fully faithful if and only if \( \tau \text{id}_k: A^2 \Rightarrow \text{Hom}_B(k, k) \) is a fibered equivalence. In the virtual equipment of modules, this condition can be rephrased in a number of ways:

**9.4.4. Lemma.** A functor \( k: A \to B \) is fully faithful when any of the following equivalent conditions hold:

(i) The square

\[
\begin{array}{ccc}
A & \xrightarrow{k} & A \\
\downarrow_{k} & & \downarrow_{k} \\
B & \xrightarrow{k} & B
\end{array}
\]

is exact.

(ii) The unary cell \( \text{id}_k: \text{Hom}_A \Rightarrow \text{Hom}_B(k, k) \) is a composite.

(iii) The module map \( \text{id}_k \) defines an equivalence of modules \( \text{Hom}_A \cong \text{Hom}_B(k, k) \) from \( A \) to \( A \).

Proof. After unpacking the definitions, the equivalence follows from the nullary and unary composites of Lemma 8.3.9 and the composition relation \( \text{Hom}_A \otimes \text{Hom}_A \cong \text{Hom}_A \) of Lemma 8.3.10.

Famously, pointwise left and right extensions along fully faithful functors are genuine extensions, in the sense that the universal natural transformation is an isomorphism.

**9.4.5. Proposition (extensions along fully faithful functors).** If

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow_{k} & & \downarrow_{r} \\
B & \xrightarrow{\nu} & C
\end{array}
\]

is a pointwise right extension and \( k \) is fully faithful, then \( \nu \) is an isomorphism.

Proof. Pasting the pointwise right extension in the statement with the exact square of Lemma 9.4.4 yields a pointwise right extension diagram, whose universal property in the homotopy 2-category can be used to construct an inverse isomorphism to \( \nu \):

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow_{r \epsilon} & & \downarrow_{\nu \epsilon} \\
A & \xrightarrow{f \nu} & C
\end{array}
\]

The dual result, that the 2-cell in a pointwise left extension along a fully faithful functor is invertible, is left to Exercise 9.4.ii.
9.4.6. **Proposition.** A right adjoint \( u : A \to B \) is fully faithful if and only if the counit \( \epsilon : fu \Rightarrow \text{id}_A \) is an isomorphism.

**Proof.** If \( f \dashv u \) with counit \( \epsilon : fu \Rightarrow \text{id}_A \), then by Proposition 9.4.1, the counit \( \epsilon : fu \Rightarrow \text{id}_A \) is exact. If \( u \) is fully faithful, then by Lemma 9.2.10 the composite rectangle below is also exact.

```
\[
\begin{array}{ccc}
A & \xrightarrow{u} & A \\
\downarrow{\epsilon} & & \downarrow{u} \\
A & \xleftarrow{f} & B
\end{array}
\]
```

Unpacking Definition 9.2.2, this is to say, by Lemmas 8.3.10 and 8.3.9, that that the image of \( \epsilon \) under the contravariant embedding of Definition 8.4.12 induces an equivalence of modules \( \epsilon^* : \text{Hom}_A \cong \text{Hom}_A(fu, A) \). By Proposition 8.4.11, this embedding is fully faithful, so it follows that \( \epsilon : fu \Rightarrow \text{id}_A \) is an isomorphism.

Conversely, assume \( f \dashv u \) with invertible counit \( \epsilon : fu \cong \text{id}_A \). By Corollary 8.4.9, we have a canonical composite \( \text{Hom}_A(f, A) \otimes \text{Hom}_B(u, B) \cong \text{Hom}_A(fu, A) \). Composing with the transposing equivalence \( \text{Hom}_B(B, u) \cong \text{Hom}_A(f, A) \) of Proposition 9.4.1(ii), then gives another composite \( \text{Hom}_B(B, u) \otimes \text{Hom}_B(u, B) \cong \text{Hom}_A(fu, A) \). By Corollary 8.4.8, we have a third composite \( \text{Hom}_B(B, u) \otimes \text{Hom}_B(u, B) \cong \text{Hom}_B(u, u) \). Factoring one composite through the other we obtain an equivalence \( \text{Hom}_A(fu, A) \cong \text{Hom}_B(u, u) \) which composes with the equivalence \( \epsilon^* : \text{Hom}_A \cong \text{Hom}_A(fu, A) \) induced by the invertible counit to define a composite equivalence of modules \( \text{Hom}_A \cong \text{Hom}_B(u, u) \), proving, by Lemma 9.4.4, that \( u : A \to B \) is fully faithful. \( \Box \)

**Exercises.**

9.4.i. **Exercise.** Show that the unit

```
\[
\begin{array}{ccc}
A & \xleftarrow{\eta} & B \\
\downarrow{u} & & \downarrow{f} \\
B & \xrightarrow{\epsilon} & A
\end{array}
\]
```

of an adjunction \( f \dashv u \) defines an exact square.

9.4.ii. **Exercise.** Prove that if

```
\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow{k} & & \downarrow{\lambda} \\
B & \xrightarrow{\epsilon} & \text{Fun}(X, A)
\end{array}
\]
```

is a pointwise left extension and \( k \) is fully faithful, then \( \lambda \) is an isomorphism.

**9.5. Limits and Colimits as Pointwise Kan Extensions**

Recall from Definition 1.2.23 that an \( \infty \)-cosmos \( \mathcal{K} \) is cartesian closed if for any \( J \in \mathcal{K} \) there is a cosmological functor \( (-)^J : \mathcal{K} \to \mathcal{K} \) equipped with a simplicial natural isomorphism

\[
\text{Fun}(X \times J, A) \cong \text{Fun}(X, A^J).
\]
It follows that elements \( f : 1 \to A^J \) in the \( \infty \)-category of \( J \)-shaped diagrams in \( A \) correspond bijectively to functors \( f : J \to A \) between \( \infty \)-categories. In such contexts, Definition 2.3.7 defined limits and colimits of an \( \infty \)-category indexed diagram \( f : J \to A \) to be absolute right and left liftings, respectively:

\[
\begin{array}{c}
\lim f & \xrightarrow{\varepsilon} & A \\
\downarrow & & \downarrow \Delta \\
1 & \xrightarrow{f} & A^J
\end{array}
\quad \quad \quad \quad
\begin{array}{c}
\colim f & \xleftarrow{\eta} & A \\
\uparrow & & \uparrow \Delta \\
1 & \xleftarrow{f} & A^J
\end{array}
\]

In this section, we use pointwise right and left extensions to define limits and colimits for arbitrary functors between \( \infty \)-categories in \( \infty \)-cosmoi that are not necessarily cartesian closed. After observing that these notions recover the ones already established in cartesian closed \( \infty \)-cosmoi, we turn to the task of extending other results of Chapter 2 to the general setting.

9.5.1. Definition. A limit of a diagram of \( \infty \)-categories \( f : J \to A \) is given by a pointwise right extension as below-left:

\[
\begin{array}{c}
J & \xrightarrow{f} & A \\
\downarrow & \varepsilon & \downarrow \lim f \\
1 & \xrightarrow{\lim f} & A^J
\end{array}
\]

while a colimit of a diagram of \( \infty \)-categories \( f : J \to A \) is given by a pointwise left extension as above-right.

As in Definition 2.3.7, we refer to the natural transformations \( \varepsilon \) and \( \eta \) as the limit cone and colimit cone, respectively. Our first task is to reconcile these definition with the one given previously in cartesian closed \( \infty \)-cosmoi:

9.5.2. Proposition. In a cartesian closed \( \infty \)-cosmos any limit as encoded by the absolute right lifting diagram below-right transposes to define a pointwise right extension diagram as below-left:

\[
\begin{array}{c}
J & \xrightarrow{f} & A \\
\downarrow & \varepsilon & \downarrow \lim f \\
1 & \xrightarrow{\lim f} & A^J
\end{array} \quad \iff \quad
\begin{array}{c}
\lim f & \xrightarrow{\varepsilon} & A \\
\downarrow & \downarrow \Delta \\
1 & \xrightarrow{f} & A^J
\end{array}
\]

Conversely, any pointwise right extension diagram of this form transposes to define a limit in \( A \).

Proof. By Lemma 9.2.1, the universal property of an absolute right lifting diagram as below-left transposes to the universal property of a right extension diagram that is stable under pasting with pullback squares:

\[
\begin{array}{c}
\lim f & \xrightarrow{\varepsilon} & C \\
\downarrow & \downarrow \Delta \\
1 & \xrightarrow{f} & C^A
\end{array} \quad \iff \quad
\begin{array}{c}
A & \xrightarrow{f} & C \\
\downarrow & \varepsilon & \downarrow \lim f \\
1 & \xrightarrow{\lim f} & A^J
\end{array}
\]

Since comma squares over cospans whose codomain is the terminal \( \infty \)-category reduce to pullbacks, we conclude from Theorem 9.3.3(ii) that \( \varepsilon : \Delta \lim f \Rightarrow f \) is an absolute right lifting diagram if and only if \( \varepsilon : \lim f ! \Rightarrow f \) is a pointwise right extension. \( \square \)
In classical category theory, there is a well-known formula that calculates the values of a pointwise right Kan extension "pointwise" as limits. A dual colimit formula can be used to calculate pointwise left Kan extensions. These can now be recovered, essentially as tautologies.

9.5.3. PROPOSITION. For any pointwise right extension

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow{k} & & \downarrow{r} \\
B & \xrightarrow{\eta} & C
\end{array}
\]

and any element \(b: 1 \to B\), the element \(rb: 1 \to C\) is the limit of the diagram

\[
\text{Hom}_B(b,k) \xrightarrow{p_1} A \xrightarrow{f} C
\]

while for any pointwise left extension

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow{k} & & \downarrow{\ell} \\
B & \xrightarrow{\mu} & C
\end{array}
\]

and any element \(b: 1 \to B\), the element \(\ell b: 1 \to C\) is the colimit of the diagram

\[
\text{Hom}_B(k,b) \xrightarrow{p_0} A \xrightarrow{f} C
\]

Proof. By Theorem 9.3.3(ii), the composite

\[
\begin{array}{ccc}
\text{Hom}_B(b,k) & \xrightarrow{p_1} & A \xrightarrow{f} C \\
\downarrow{} & & \downarrow{k} \\
1 & \xrightarrow{b} & B
\end{array}
\]

is a pointwise right extension. By Definition 9.5.1 this can be interpreted as saying that \(rb: 1 \to B\) defines the limit of the restriction of the diagram \(f: A \to C\) along \(p_1: \text{Hom}_B(b,k) \to A\). \(\square\)

In Definition 2.2.1, initial and terminal elements in \(A\) were defined respectively as left or right adjoints to the unique functor \(!: A \to 1\)

\[
\begin{array}{ccc}
A & \xleftarrow{i} & 1 \\
\downarrow{t} & & \downarrow{t} \\
1 & & 1
\end{array}
\]

or equivalent, by Example 2.3.9, as colimits or limits for the empty diagram in \(A \cong 1\). As observed there, an initial element may also be characterized as a limit and a terminal element may be characterized as a colimit of the identity diagram \(\text{id}_A: A \to A\), as we now show for \(\infty\)-cosmoi that are not necessarily cartesian closed:

9.5.4. PROPOSITION. For an \(\infty\)-category \(A\):

(i) An element \(t: 1 \to A\) is terminal if and only if it defines a colimit for the identity functor \(\text{id}_A: A \to A\) in which case the unit for the adjunction \(! \dashv t\) defines the colimit cone.
(ii) An element $i : 1 \to A$ is initial if and only if it defines a limit for the identity functor $\text{id}_A : A \to A$ in which case the counit for $i \dashv !$ defines the limit cone.

**Proof.** We prove (ii). By Definition 2.2.1, an element $i : 1 \to A$ is initial if and only if it defines a right adjoint to the unique functor $!: A \to 1$. If this adjunction exists, then by Proposition 9.4.1, the counit defines a pointwise right extension diagram

$${\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}={\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}$$

which by Definition 9.5.1 expresses $i$ as the limit of the diagram $\text{id}_A : A \to A$.

Conversely, we must argue that a pointwise right extension diagram $(i, \varepsilon : i! \Rightarrow \text{id}_A)$ gives rise to an adjunction $i \dashv !$ with counit $\varepsilon$. By Lemma 2.2.2 it suffices to show that $\varepsilon i = \text{id}_i$. By naturality of whiskering, as expressed by Lemma B.1.3, the horizontal composite of $\varepsilon$ with itself gives rise to an equation $\varepsilon i \cdot \varepsilon = \varepsilon \cdot \varepsilon i!$. Since the $\infty$-category $1$ is 2-terminal, $\varepsilon i = \text{id}_i$, so this reduces to the pasting equation:

$${\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}={\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}$$

By the uniqueness statement in the universal property of right extensions, it follows that $\varepsilon i = \text{id}_i$ as desired. □

Recall from Definition 2.4.6 that a functor $k : I \to J$ is **final** if and only if for any $\infty$-category $A$, the square

$${\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}={\begin{array}{c}
A \\
\downarrow \nearrow
\end{array}}$$

preserves and reflects all absolute left lifting diagrams. Dually a functor $k : I \to J$ is **initial** if this square preserves and reflects all absolute right lifting diagrams. We can now give a more concise formulation of these notions.

**9.5.5. Definition.** A functor $k : I \to J$ is **final** if and only if the square below-left is exact and **initial** if and only if the square below-right is exact.

$${\begin{array}{ccc}
I & \xrightarrow{k} & J \\
\downarrow & & \downarrow \\
1 & \xrightarrow{!} & 1
\end{array}}$$

$${\begin{array}{ccc}
I & \xleftarrow{k} & J \\
\downarrow & & \downarrow \\
1 & \xleftarrow{!} & 1
\end{array}}$$

Note that the functor $!: J \to 1$ is represented on the right and on the left by the modules $J \xrightarrow{1} 1$ and $1 \xrightarrow{1} J$. So we see that $k : I \to J$ is **final** if and only if the map of spans below-left is a composite in the
virtual equipment of modules

\[
\begin{array}{cc}
\text{Hom}(J, k) & \text{Hom}(k, J) \\
1 & 1
\end{array}
\]

while \( k: I \to J \) is initial if and only if the map of spans above-right is a composite.

9.5.6. Remark. As discussed in Digression 9.2.5, in \( \infty \)-cosmoi of \((\infty, 1)\)-categories exact squares are automatically strongly exact, in which case the universal property satisfied by final functors can be enriched. Since modules from \( 1 \) to \( J \) reduce to discrete cartesian fibrations over \( J \), in such contexts finality of \( k: I \to J \) implies that for every discrete cartesian fibration \( p: E \to J \), the map

\[
\begin{array}{ccc}
\text{Fun}_J(J, E) & \xrightarrow{\sim} & \text{Fun}_J(\text{Hom}_J(J, k), E) \\
& \sim & \rightarrow \\
& \sim & \rightarrow
\end{array}
\]

is an equivalence, the first equivalence by strong exactness and the second by the Yoneda lemma of Corollary 5.7.23.

In fact, \( \infty \)-cosmoi of \((\infty, 1)\)-categories are strongly closed, meaning that right extensions and right liftings of modules always exist and satisfy a universal property expressed as an equivalence of Kan complexes, not merely a bijection of cells in the virtual equipment. It follows, by the strong analog of Exercise 9.1.iii, that \(- \circ k: \text{Fun}_J(J, E) \to \text{Fun}_J(I, E)\) defines an equivalence for all discrete cartesian fibrations over \( J \) if and only if the square of Definition 9.5.5 is strongly exact. Thus, in the \( \infty \)-cosmos of quasi-categories, our notion of final functor is equivalent to a definition of final functor that Lurie attributes to Joyal [74, 4.1.1.1].

We now show that limits are preserved and reflected by reindexing along initial functors.

9.5.7. Proposition. If \( k: I \to J \) is initial and \( f: J \to A \) is any diagram, then a limit of \( f \) also defines a limit of \( f_k: I \to A \) and conversely if the limit of \( f_k: I \to A \) exists, then it also defines a limit of \( f: J \to A \).

Proof. By Definition 9.5.1, a limit of \( f \) defines a pointwise right extension as below left, which by Corollary 9.3.4 and Definition 9.5.5 gives rise to another pointwise right extension below-right.

\[
\begin{array}{cc}
J & A \\
\downarrow \ell & \downarrow \ell \\
1 & 1 \\
\hline
I & A \\
\downarrow \ell & \downarrow \ell \\
1 & 1
\end{array}
\]

By Definition 9.5.1 again, this tells us that \( \ell \) is the limit of \( f_k \).

For the converse, suppose we are given a pointwise right extension diagram

\[
\begin{array}{cc}
I & A \\
\downarrow \ell & \downarrow \ell \\
1 & 1
\end{array}
\]

314
By Theorem 9.3.3(iii), this universal property tells us that for any compatible sequence of modules $E_1 \times \cdots \times E_n$ from 1 to $A$, composing with $\mu : \text{Hom}(1, !) \times \text{Hom}_A(A, \ell) \Rightarrow \text{Hom}_A(A, fk)$ defines a bijection between cells $E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_A(A, \ell)$ and the cells below-left:

$$
\begin{array}{ccc}
I & \rightarrow & 1 \\
\downarrow & & \downarrow \\
\text{Hom}_A(A, fk) & \rightarrow & A
\end{array}
\quad
\begin{array}{ccc}
J & \rightarrow & 1 \\
\downarrow & & \downarrow \\
\text{Hom}_A(A, f) & \rightarrow & A
\end{array}
$$

By Corollary 8.4.6, the cells above-left stand in bijection with the cells above-right.

To say that $k : I \rightarrow J$ is initial means, by Definition 9.5.5, that the map $\text{Hom}_j(k, J) \times \text{Hom}_i(1, !) \Rightarrow \text{Hom}_i(1, !)$ of modules from $J$ to 1 induced by the identity is a composite. Hence, the cells above-right stand in bijection with cells of the form:

$$
\begin{array}{ccc}
J & \rightarrow & 1 \\
\downarrow & & \downarrow \\
\text{Hom}_A(A, f) & \rightarrow & A
\end{array}
$$

The composite bijection between cells $E_1 \times \cdots \times E_n \Rightarrow \text{Hom}_A(A, \ell)$ and cells of this form asserts exactly that the cell $\nu : \text{Hom}_i(1, !) \times \text{Hom}_A(A, \ell) \Rightarrow \text{Hom}_A(A, f)$ that corresponds to the identity cell $\text{id} : \text{Hom}_A(A, \ell) \Rightarrow \text{Hom}_A(A, f)$ under this series of bijections displays $1 \Rightarrow \text{Hom}_A(A, \ell)$ as the right extension of $J \Rightarrow 1$ along $J \Rightarrow 1$. Unpacking the bijections that defined $\nu$, we see that $\nu k = \mu$.

Thus $\nu : \ell ! \Rightarrow f$ is a pointwise right extension and by Proposition 9.5.2 we conclude that $\ell : 1 \rightarrow A$ also defines a limit of $f : J \rightarrow A$ as claimed.  

Exercises.

9.5.i. Exercise. Suppose the diagram below-left is a pointwise right extension diagram in a cartesian closed $\infty$-cosmos.

$$
\begin{array}{ccc}
J & \rightarrow & A \\
\downarrow & \searrow & \downarrow \uparrow \\
K & \rightarrow & 1 & \rightarrow & A^k
\end{array}
$$

Show that its transpose above-right defines an absolute right lifting diagram in the homotopy 2-category, which moreover is stable under pasting with the square $A^\phi$ induced from any exact square $\phi$.

9.5.ii. Exercise. Show that if $k : I \rightarrow J$ is a right adjoint then the square

$$
\begin{array}{ccc}
I & \rightarrow & J \\
\downarrow & \searrow & \downarrow \\
1 & \rightarrow & 1
\end{array}
$$

is exact.
9.6. Weighted Limits and Colimits of \( \infty \)-Categories

In this section we generalize the limits and colimits of diagrams between \( \infty \)-categories encoded by Definition 9.5.1 to limits and colimits weighted by a module. The notions of weighted limit and colimit subsume Definition 9.5.1 — see Exercise 9.6.i — and are quite natural from the point of view of the virtual equipment of modules. This can be understood as the \( \infty \)-categorical version of the theory introduced in §A.6 in the context of enriched categories, though from the outset we allow our weights to be profunctors, as in Exercise A.6.iv.

9.6.1. Definition. Given a module \( A \xrightarrow{W} B \) and a functor \( f : A \to C \), a functor \( \lim_W f : B \to C \) defines the \( W \)-weighted limit of \( f \) if it covariantly represents the right extension of \( \text{Hom}_C(C, f) \) along \( W \):

\[
\begin{array}{ccc}
A & \xrightarrow{W} & B \\
\downarrow \scriptstyle{\lambda} & & \downarrow \scriptstyle{\nu} \\
A & \rightarrow & C \\
\end{array}
\]

\[
\begin{array}{ccc}
C & \rightarrow & A \\
\downarrow \scriptstyle{\mu} & & \downarrow \scriptstyle{\nu} \\
C & \xrightarrow{\text{Hom}_C(C, \lim_W f)} & B \\
\end{array}
\]

Dually, given a module \( A \xrightarrow{W} B \) and a functor \( g : B \to C \), a functor \( \text{colim}_W g : A \to C \) defines the \( W \)-weighted colimit of \( g \) if it contravariantly represents the right lifting of \( \text{Hom}_C(g, C) \) through \( W \):

\[
\begin{array}{ccc}
C & \rightarrow & A \\
\downarrow \scriptstyle{\mu} & & \downarrow \scriptstyle{\nu} \\
C & \rightarrow & B \\
\end{array}
\]

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow \scriptstyle{\lambda} & & \downarrow \scriptstyle{\nu} \\
A & \xrightarrow{\text{Hom}_C(\text{colim}_W g, C)} & C \\
\end{array}
\]

By comparing Definition 9.6.1 with Theorem 9.3.3(iii) we see that pointwise right and left extensions can be understood as special cases of weighted limits and colimits; see also Example A.6.16.

9.6.2. Lemma. The pointwise right extension of \( f : A \to C \) along \( k : A \to B \) is the limit of \( f \) weighted by \( A \xrightarrow{\text{Hom}_B(k, B)} B \), while the pointwise left extension of \( f \) along \( k \) is the colimit of \( f \) weighted by \( B \xrightarrow{\text{Hom}_B(k, B)} A \).

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow \scriptstyle{\nu} & & \downarrow \scriptstyle{\nu} \\
B & \rightarrow & \text{ran}_k f \equiv \text{lim}_{\text{Hom}_B(k, B)} f \\
\end{array}
\]

\[
\begin{array}{ccc}
A & \xrightarrow{f} & C \\
\downarrow \scriptstyle{\lambda} & & \downarrow \scriptstyle{\lambda} \\
B & \rightarrow & \text{lan}_k f \equiv \text{colim}_{\text{Hom}_B(k, B)} f \\
\end{array}
\]

Proof. By Theorem 9.3.3(iii) a pointwise right extension defines a right extension of modules while a pointwise left extension defines a right lifting of modules:

\[
\begin{array}{ccc}
A & \rightarrow & B \\
\downarrow \scriptstyle{\nu} & & \downarrow \scriptstyle{\lambda} \\
A & \rightarrow & C \\
\end{array}
\]

\[
\begin{array}{ccc}
C & \rightarrow & B \\
\downarrow \scriptstyle{\lambda} & & \downarrow \scriptstyle{\lambda} \\
C & \rightarrow & A \\
\end{array}
\]

By Definition 9.6.1 this means that \( \text{ran}_k f \equiv \text{lim}_{\text{Hom}_B(k, B)} f \) and \( \text{lan}_k f \equiv \text{colim}_{\text{Hom}_B(k, B)} f \) as claimed. \( \square \)
In enriched category theory, weighted limits or colimits with representable weights are computed by evaluating at the representing object. By analogy:

9.6.3. Lemma. For any functor \( f : A \to C \) and generalized element \( a : X \to A \), the restriction \( fa : X \to C \) is the limit of \( f \) weighted by \( A \xrightarrow{\text{Hom}_A(a, A)} X \) and also the colimit of \( f \) weighted by \( X \xrightarrow{\text{Hom}_A(A, a)} A \).

Proof. The two assertions are dual. By Lemma 9.1.4 the right extension of \( A \xrightarrow{\text{Hom}_C(C, f)} C \) along \( A \xrightarrow{\text{Hom}_A(a, A)} X \) is given by the restricted module \( X \xrightarrow{\text{Hom}_C(C, \lim_W f)} C \), while the right lifting of \( C \xrightarrow{\text{Hom}_A(A, a)} A \) through \( X \xrightarrow{\text{Hom}_A(A, a)} A \) is given by the restricted module \( C \xrightarrow{\text{Hom}_C(fa, C)} X \).

In the terminology of Definition 9.6.1 this says that the composite functor \( fa : X \to C \) is the limit of \( f \) weighted by the contravariant module representing \( a \) and also the colimit of \( f \) weighted by the covariant module representing \( a \). \( \square \)

By Proposition 9.1.6 and its dual we have immediately:

9.6.4. Proposition. For any functors \( f : A \to E \) and \( g : C \to E \) and weights \( A \xrightarrow{W} B \) and \( B \xrightarrow{V} C \), the functors \( \operatorname{lim}_W (\operatorname{colim}_V f) \) and \( \operatorname{colim}_W (\operatorname{lim}_V g) \) are isomorphic and the functors \( \operatorname{colim}_W (\operatorname{colim}_V g) \) and \( \operatorname{colim}_W (\operatorname{lim}_V g) \) are isomorphic whenever these weighted limits and colimits and the composite weight exist. \( \square \)

Using this result, we are able to deduce various formulae for computing weighted limits and colimits. The first of these determines the values of a weighted limit or colimit functor at a generalized element of its domain.

9.6.5. Lemma. If \( f : A \to C \) admits a limit \( \operatorname{lim}_W f : B \to C \) weighted by \( A \xrightarrow{W} B \) then for any generalized element \( b : X \to B \), the functor \( \operatorname{lim}_W f \circ b : X \to C \) is isomorphic to the limit of \( f \) weighted by \( A \xrightarrow{W(\{a\}, 1)} X \).

Dually, if \( g : B \to C \) admits a colimit \( \operatorname{colim}_W g : A \to C \) weighted by \( W \xrightarrow{V} A \) then for any generalized element \( a : Y \to A \), the functor \( \operatorname{colim}_W g \circ A : Y \to C \) is isomorphic to the colimit of \( g \) weighted by \( Y \xrightarrow{V(1, a)} B \).

Proof. Recall from Proposition 8.4.7 that the module \( W(b, 1) \) is the composite \( W \otimes \text{Hom}_B(b, B) \). Thus, by Proposition 9.6.4, the \( W(b, 1) \)-weighted limit of \( f \) if it exists, is the functor that right-represents the right extension of the module \( \text{Hom}_C(C, \operatorname{lim}_W f) \) along the module \( \text{Hom}_B(b, B) \). By Lemma 9.6.3, the right extension of \( \text{Hom}_C(C, \operatorname{lim}_W f) \) along \( \text{Hom}_B(b, B) \) is given by the restriction \( \text{Hom}_C(C, \text{lim}_W f \circ b) \). By Definition 9.6.1, it follows that \( \operatorname{lim}_W f \circ b : X \to C \) defines the \( W(b, 1) \)-weighted limit of \( f : A \to C \), as claimed. \( \square \)

A second useful computational result reduces general weighted limits or weighted colimits to right or left extensions in the homotopy 2-category.

9.6.6. Lemma. Consider a weight \( A \xrightarrow{W} B \) encoded by the two-sided isofibration \( A \xleftarrow{W} W \xrightarrow{p} B \).
(i) For any functor \( f : A \to C \) the weighted limit \( \lim_W W \) is given by the pointwise right extension
\[
\begin{array}{ccc}
W & \xrightarrow{q} & A \\
p & \nearrow & \\
B & \xrightarrow{\text{ran}_p(fq) \cong \lim_W f} & C
\end{array}
\]

(ii) For any functor \( g : B \to C \) the weighted colimit \( \text{colim}_W W \) is given by the pointwise left extension
\[
\begin{array}{ccc}
W & \xrightarrow{p} & B \\
q & \searrow & \\
A & \xrightarrow{\text{lan}_q(fp) \cong \text{colim}_W f} & C
\end{array}
\]

In particular, limits weighted by modules from \( A \) to \( 1 \) and colimits weighted by modules from \( 1 \) to \( B \) reduce to ordinary limits and colimits.

**Proof.** Recall from Proposition 8.3.11 that any module \( A \xleftarrow{q} W \xrightarrow{p} B \) factors as a composite \( \text{Hom}(q, A) \otimes \text{Hom}(B, p) \cong W \). Thus by Proposition 9.6.4, Lemma 9.6.5, and Lemma 9.6.2
\[
\lim_W f \cong \lim_{\text{Hom}(B, p)} \left( \lim_{\text{Hom}(q, A)} f \right) \cong \lim_{\text{Hom}(B, p)} (f q) \cong \text{lan}_p(f q). \]

9.6.7. *Digression.* We can use weighted limits to re-express stability of pointwise right extensions under pasting with comma squares
\[
\begin{array}{ccc}
\text{Hom}_B(b, k) & \xrightarrow{p_1} & A \\
p_0 & \searrow & \text{ran}_f \downarrow \phi & \searrow & \text{ran}_f & \searrow \text{ran}_0 p_1 \\
\text{ran}_k f \circ b & \cong & \text{ran}_k f \circ b & \cong & \text{ran}_k f \circ b & \cong \text{ran}_k f \circ b
\end{array}
\]

By Lemma 9.6.2, the pointwise right extension \( \text{ran}_k f : B \to C \) encodes the weighted limit functor \( \lim_{\text{Hom}_B(B, k)} f : B \to C \). Now by Lemma 9.6.5, the composite
\[
\text{ran}_k f \circ b \cong \lim_{\text{Hom}_B(B, k)} f \circ b \cong \lim_{\text{Hom}_B(B, k)} f
\]
is the limit of \( f : A \to C \) weighted by the module \( A \xrightarrow{\text{Hom}_A(p_1, A)} X \). By Proposition 8.3.11, the module \( \text{Hom}_B(b, k) \) is the composite \( \text{Hom}_A(p_1, A) \otimes \text{Hom}_X(X, p_0) \) of the modules contravariantly and covariantly represented by its legs. Thus by Proposition 9.6.4
\[
\text{ran}_k f \circ b \cong \lim_{\text{Hom}_B(b, k)} f \circ b \cong \lim_{\text{Hom}_B(b, k)} f \cong \lim_{\text{Hom}_X(X, p_0)}(\lim_{\text{Hom}_A(p_1, A)} f).
\]

Since by Lemma 9.6.3, the limit of \( f : A \to C \) weighted by \( \text{Hom}_A(p_1, A) \) is given by the composite functor \( f p_1 : \text{Hom}_B(b, k) \to C \), it follows that
\[
\text{ran}_k f \circ b \cong \lim_{\text{Hom}_B(b, k)} f \circ b \cong \lim_{\text{Hom}_B(b, k)} f \cong \lim_{\text{Hom}_X(X, p_0)}(\lim_{\text{Hom}_A(p_1, A)} f) \cong \lim_{\text{Hom}_X(X, p_0)}(f p_1) \cong \text{ran}_0(f p_1).
\]

In a cartesian closed \( \infty \)-cosmos, Theorem 2.4.2 proves right adjoints preserve limits and left adjoints preserve colimits of \( \infty \)-category indexed diagrams. We can now extend this result to weighted limits and colimits, while dropping the hypothesis that the ambient \( \infty \)-cosmos is cartesian closed.
9.6.8. Theorem (weighted RAPL/LAPC). Right adjoints preserve weighted limits and left adjoints preserve weighted colimits.

Proof. Consider a weight $\mathcal{W} \colon J \to K$, a diagram $d : J \to A$, and an adjunction with right adjoint $u : A \to B$ and left adjoint $f : B \to A$. The weighted limit $\lim \mathcal{W} d : K \to A$ defines a right extension of modules

\[
\begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{\Hom_A(\lim \mathcal{W} d)} A \\
| \quad \downarrow \lambda \\
J \xrightarrow{\Hom_A(A, d)} A
\end{array}
\]

Our task is to demonstrate that the cell $u \lambda$ defined by the unique factorization of the cell below-left through the composite below-right

\[
\begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{\Hom_A(\lim \mathcal{W} d)} A \xrightarrow{\Hom_B(B, u)} B \\
\downarrow \quad \downarrow \circ \\
J \xrightarrow{\Hom_A(A, d)} A \xrightarrow{\Hom_B(B, u)} B
\end{array} = \begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{\Hom_A(\lim \mathcal{W} d)} A \xrightarrow{\Hom_B(B, u)} B \\
\downarrow \quad \downarrow \circ \\
J \xrightarrow{\Hom_A(A, d)} A \xrightarrow{\Hom_B(B, u)} B
\end{array}
\]

is again a right extension of modules.

To that end consider a cell

\[
\begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{E_1} \cdots \xrightarrow{E_n} B \\
| \quad \downarrow \\
J \xrightarrow{\Hom_B(B, u d)} B
\end{array}
\]

By Corollary 4.1.3, there is an equivalence of modules $\Hom_B(B, u d) \simeq \Hom_A(f, d)$ and hence we have a restriction cell

\[
\begin{array}{c}
J \xrightarrow{\mathcal{W}} B \\
\downarrow \rho \\
J \xrightarrow{\Hom_A(A, d)} A
\end{array} = \begin{array}{c}
J \xrightarrow{\mathcal{W}} B \\
\downarrow \rho \\
J \xrightarrow{\Hom_A(A, d)} A
\end{array}
\]

in the virtual equipment of modules. By Proposition 8.2.1, composition with $\rho$ induces a bijection between the cells $\mathcal{W} \times E_1 \times \cdots \times E_n \Rightarrow \Hom_B(B, u d)$ and cells of the form displayed below-left

\[
\begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{E_1} \cdots \xrightarrow{E_n} B \\
| \quad \downarrow f \\
J \xrightarrow{\Hom_A(A, d)} A
\end{array} \leftrightarrow \begin{array}{c}
J \xrightarrow{\mathcal{W}} K \xrightarrow{E_1} \cdots \xrightarrow{E_n} B \xrightarrow{\Hom_A(A, f)} A \\
| \quad \downarrow f \\
J \xrightarrow{\Hom_A(A, d)} A
\end{array}
\]

319
and by Theorem 8.4.4 these cells are in natural bijection with cells of the form displayed above-right. Since \( \text{Hom}_A(A, \lim_W d) \) is a right extension of \( \text{Hom}_A(A, d) \) along \( W \), such cells are in bijection with cells of the form below-left

\[
\begin{array}{cccccc}
K & E_1 & \cdots & E_n & \text{Hom}_A(A, f) & A \\
\downarrow & & & & \downarrow & \\
\text{Hom}_A(A, \lim_W d) & A
\end{array}
\]

\[
\begin{array}{cccccc}
K & E_1 & \cdots & E_n & \text{Hom}_A(A, \lim_W d) & A \\
\downarrow & & & & \downarrow & \\
K & A
\end{array}
\]

and by Theorem 8.4.4 again these cells are in natural bijection with cells of the form displayed above-right. By Proposition 8.2.1, such cells stand in bijection with the cells defined by factoring through the restriction \( \text{Hom}_A(f, \lim_W d) \) of \( \text{Hom}_A(A, \lim_W d) \) along \( f : B \to A \). By Corollary 4.1.3, there is an equivalence of modules \( \text{Hom}_A(f, \lim_W d) \simeq \text{Hom}_B(B, u \lim_W d) \) so via this restriction the cells are in bijection to cells of the form

\[
\begin{array}{cccccc}
K & E_1 & \cdots & E_n & B \\
\downarrow & & & & \\
\text{Hom}_B(B, u \lim_W d) & B
\end{array}
\]

When we start from the identity cell at the module \( \text{Hom}_B(B, u \lim_W d) \) and reverse this composite bijection we obtain the cell \( u \lambda : W \times \text{Hom}_B(B, u \lim_W d) \Rightarrow \text{Hom}_B(B, ud) \), so this proves that \( u \lambda \) displays \( \text{Hom}_B(B, u \lim_W d) \) as the right extension of \( \text{Hom}_B(B, ud) \) along \( W \). Thus \( u \lim_W d \) is the \( W \)-weighted limit of \( ud \) as claimed.

Theorem 9.6.8 should be compared with Proposition A.6.21, which observes that the right adjoints of enriched category theory preserve weighted limits, as defined in §A.6. In \( \infty \)-cosmoi of \((\infty, 1)\)-categories, we can think of the results of this section as developing an analogous theory of weighted limits and colimits for categories weakly enriched over \( \infty \)-groupoids. In particular, adjunctions between \((\infty, 1)\)-categories are automatically enriched over \( \infty \)-groupoids, as alluded to in Remark 4.1.4, so they should be expected to preserve limits weighted by modules, whose fibers are \( \infty \)-groupoids.

Exercises.

9.6.i. Exercise. Determine weights \( W_{\lim} \) and \( W_{\colim} \) so that the \( W_{\lim} \)-weighted limit of a diagram \( f \) is the ordinary limit of \( f \), as defined in 9.5.1, and the \( W_{\colim} \)-weighted colimit is the ordinary colimit.

9.6.ii. Exercise. Define the tensor and cotensor of an element \( a : 1 \to A \) of an \( \infty \)-category by a discrete \( \infty \)-category \( S \) as a weighted colimit and weighted limit respectively, and compare this construction with Definition 4.3.7.
Part III

Change of Model and Model Independence
CHAPTER 10

Cosmological Biequivalences

In this chapter we study a certain class of cosmological functors between ∞-cosmoi that do not merely preserve ∞-categorical structure but also reflect and create it. We refer to these functors as cosmological biequivalences because the 2-functors they induce between homotopy 2-categories are biequivalences: surjective on objects up to equivalence and defining a local equivalence of hom-categories. Informally, we refer to cosmological biequivalences as “change-of-model functors.” For example, the four ∞-cosmoi introduced in Example 1.2.24 whose objects model (∞, 1)-categories are connected by the following biequivalences briefly described in Example 1.3.7 and revisited in §E.2:

\[
\begin{array}{ccc}
CSS & \xleftarrow{\text{disc}} & Segal \\
\downarrow^{\text{nerve}} & & \downarrow^{\text{nerve}} \\
\mathcal{Q}Cat & \xrightarrow{(-)_0} & \mathcal{C}om\mathcal{P}(\mathcal{L}) \\
\mathcal{C}om\mathcal{P} & \xleftarrow{\text{nerve}} & \mathcal{Q}Cat \\
\end{array}
\]

(10.0.1)

In §10.1, we collect together a number of results about cosmological functors that are scattered throughout the text. In §10.2, we reintroduce the special class of biequivalences and discuss general examples. In particular, we discover that the ∞-cosmology of Chapter 6 is biequivalence-invariant: for instance, a cosmological biequivalence \( \mathcal{K} \bowtie \mathcal{L} \) induces a cosmological biequivalence \( \mathcal{C}om\mathcal{P}(\mathcal{K}) \bowtie \mathcal{C}om\mathcal{P}(\mathcal{L}) \). Then in §10.3 we establish the basic 2-categorical properties of biequivalences, which will provide the essential ingredient in the proof of the model-independence results in Chapter 11.

Since our biequivalences between ∞-cosmoi are required to be cosmological functors, resembling enriched right Quillen adjoints, the relation “admits a biequivalence to” is not symmetric. Thus, when we say that two ∞-cosmoi “are biequivalent” we mean that there exists a finite zig zag of biequivalences connecting them, in other words, that they lie in the same equivalence class under the symmetric transitive closure of the relation defined by the presence of a cosmological biequivalence. In particular, under this definition, an ∞-cosmos of (∞, 1)-categories is an ∞-cosmos that is connected by a finite zig zag of cosmological biequivalences to the ∞-cosmos of quasi-categories, or equally to any of the models in (10.0.1). Fortunately, however, as mentioned when this terminology was first introduced in §1.3, in this special case a simpler characterization is possible. We prove in Proposition 10.2.2 that an ∞-cosmos \( \mathcal{K} \) is an ∞-cosmos of (∞, 1)-categories just when the underlying quasi-category functor \( (-)_0 : \mathcal{K} \Rightarrow \mathcal{Q}Cat \) is a cosmological biequivalence.

In §10.4, we explore the properties of formally-defined “inverses” to cosmological biequivalences. These are not guaranteed to be cosmological functors, nor even simplicial functors in the customary strict sense. The situation is analogous to 2-category theory: a 2-functor that defines a biequivalence admits an inverse biequivalence but this may only be a pseudofunctor, a notion recalled in Definition 10.4.1. Accordingly, the inverse to a cosmological biequivalence defines a “quasi-categorically enriched
pseudofunctor” or quasi-pseudofunctor for short that is not cosmological but does define a biequivalence and so that the composite endofunctors are quasi-pseudonaturally equivalent to the identity functors on each $\infty$-cosmos. These structures will reappear in Chapter 12 as tools to transport analytically-defined structures between biequivalent $\infty$-cosmoi.

10.1. Cosmological Functors

Recall from Definition 1.3.1 that a cosmological functor is a simplicial functor $F: \mathcal{K} \to \mathcal{L}$ between $\infty$-cosmoi that preserves

- the specified classes of isofibrations and
- all of the simplicial limits enumerated in 1.2.1(i).

Lemma 1.3.2 demonstrates that cosmological functors also preserve the equivalences and the trivial fibrations. By Proposition 6.3.1(i), cosmological functors preserve all flexible weighted limits, since that result reveals that these can be constructed out of simplicial limits of diagrams of isofibrations of the form listed in 1.2.1(i).

Our aim in this section is to show that cosmological functors preserve all of the $\infty$-categorical structures we have introduced — with a single notable exception discussed in Warning 10.1.9. In many cases this will not be evident from the original 2-categorical definitions (eg of cartesian fibrations in Definition 5.2.1) but can be deduced rather easier from the accompanying “internal characterization” of each categorical notion (such as given in Theorem 5.2.10(iii)).

First, we orient ourselves to the main examples. Recall Proposition 1.3.3:

10.1.1. Example (cosmological functors).

(i) For any object $A$ in an $\infty$-cosmos $\mathcal{K}$,

$$\text{Fun}(A, -): \mathcal{K} \to \mathcal{QC}at$$

defines a cosmological functor.

(ii) In particular, each $\infty$-cosmos has an underlying quasi-category functor

$$(-)_0 := \text{Fun}(1, -): \mathcal{K} \to \mathcal{QC}at,$$

defined by mapping out of the terminal $\infty$-category. We use the notation “$(-)_0$” for this functor because the underlying quasi-categories of a complete Segal space or Segal category displayed in (10.0.1) are defined by evaluating these simplicial objects at 0 and because this notation for an “underlying category” is commonly used in enriched category theory (see Definition A.1.5).

(iii) For any $\infty$-cosmos $\mathcal{K}$ and any simplicial set $U$, the simplicial cotensor defines a cosmological functor

$$(-)^U: \mathcal{K} \to \mathcal{K}.$$

(iv) For any object $A$ in a cartesian closed $\infty$-cosmos $\mathcal{K}$, exponentiation defines a cosmological functor

$$(-)^A: \mathcal{K} \to \mathcal{K}.$$

(v) For any map $f: A \to B$ in an $\infty$-cosmos $\mathcal{K}$, pullback defines a cosmological functor

$$f^*: \mathcal{K}_B \to \mathcal{K}_A.$$

In the special case of the map $!: A \to 1$, the pullback cosmological functor has the form

$$- \times A: \mathcal{K} \to \mathcal{K}_A.$$
(vi) For any cosmological functor $F: \mathcal{K} \to \mathcal{L}$ and any $A \in \mathcal{K}$, the induced map on slices

$$F: \mathcal{K}/A \to \mathcal{L}/F(A)$$

defines a cosmological functor.

Another example of a cosmological functor is provided by the nerve embedding $\text{Cat} \hookrightarrow \text{QCat}$. This is similar to but not quite prototypical of the cosmological embeddings characterized by Proposition 6.4.3 as the full inclusion is replete up to isomorphism but not up to equivalence, as in Definition 6.4.1.

10.1.2. Example (cosmological embeddings). Inclusions of the cosmologically embedded $\infty$-cosmoi are necessarily cosmological functors. Examples include:

(i) The full subcategory of discrete objects

$$\text{Disc}(\mathcal{K}) \hookrightarrow \mathcal{K}$$

defines a cosmologically embedded $\infty$-cosmos; see Proposition 6.1.6.

(ii) The inclusions

$$\mathcal{K}_T \hookrightarrow \mathcal{K} \hookleftarrow \mathcal{K}_\perp$$

of the $\infty$-cosmoi of $\infty$-categories possessing and functors preserving a terminal or initial element are cosmological. More generally, the there are cosmological embeddings

$$\mathcal{K}_{T,J} \hookrightarrow \mathcal{K} \hookleftarrow \mathcal{K}_{\perp,J}$$

of the $\infty$-cosmoi of $\infty$-categories possessing and functors preserving limits or colimits of shape $J$; see Propositions 6.4.4 and 6.4.12.

(iii) The inclusions

$$\text{Stab}(\mathcal{K}) \hookrightarrow \mathcal{K}_* \hookrightarrow \mathcal{K}$$

of the $\infty$-cosmoi of stable and pointed $\infty$-categories are cosmological embeddings; see Propositions 6.4.6 and 6.4.15.

(iv) The inclusions

$$\mathcal{R}ari(\mathcal{K})_B \hookrightarrow \mathcal{K}_B \hookleftarrow \mathcal{L}ari(\mathcal{K})_B$$

or

$$\mathcal{R}ari(\mathcal{K}) \hookrightarrow \mathcal{K}^\ast \hookleftarrow \mathcal{L}ari(\mathcal{K})$$

of $\infty$-cosmoi whose objects are isofibrations admitting a right or left adjoint right inverse are cosmological embeddings; see Corollary 6.4.7 and Proposition 6.4.9.

(v) The inclusions

$$\text{Cart}(\mathcal{K})_B \hookrightarrow \mathcal{K}_B \hookleftarrow \text{coCart}(\mathcal{K})_B$$

or

$$\text{Cart}(\mathcal{K}) \hookrightarrow \mathcal{K}^\ast \hookleftarrow \text{coCart}(\mathcal{K})$$

of the $\infty$-cosmoi of cartesian or cartesian fibrations and cartesian functors between them are cosmological; see Proposition 6.4.13. Analogous results hold for discrete co/cartesian fibrations by Proposition 6.4.14.
10.1.3. Lemma. Suppose that $\mathcal{K}' \hookrightarrow \mathcal{K}$ and $\mathcal{L}' \hookrightarrow \mathcal{L}$ are cosmological embeddings of replete sub $\infty$-cosmoi. If $F: \mathcal{K} \to \mathcal{L}$ is a cosmological functor that carries objects and 0-arrows of $\mathcal{K}'$ to objects and 0-arrows of $\mathcal{L}'$ then the restricted functor

$$
\begin{array}{ccc}
\mathcal{K}' & \xrightarrow{F} & \mathcal{L}' \\
\downarrow & & \downarrow \\
\mathcal{K} & \xrightarrow{F} & \mathcal{L}
\end{array}
$$

is cosmological.

Proof. Recall that the repleteness of Definition 6.4.1 includes the requirement that the inclusions $\mathcal{K}' \hookrightarrow \mathcal{K}$ and $\mathcal{L}' \hookrightarrow \mathcal{L}$ are full on positive dimensional arrows. So if the simplicial functor $F$ carries objects and 0-arrows of $\mathcal{K}'$ to objects and 0-arrows of $\mathcal{L}'$ then it restricts to define a simplicial functor $F': \mathcal{K}' \to \mathcal{L}'$. As cosmological embeddings create isofibrations and the simplicial limits of axiom 1.2.1(i), the restricted functor is cosmological. 

For example, by Proposition 5.2.4 and Exercise 5.3.i, pullback $f^* : \mathcal{K}_B \to \mathcal{K}_A$ preserves cartesian fibrations and cartesian functors. Thus, pullback along any functor $f: A \to B$ in $\mathcal{K}$ restricts to define a cosmological functor:

$$
\begin{array}{ccc}
\text{Cart}(\mathcal{K})_B & \xrightarrow{f^*} & \text{Cart}(\mathcal{K})_A \\
\downarrow & & \downarrow \\
\mathcal{K}_B & \xrightarrow{f^*} & \mathcal{K}_A
\end{array}
$$

10.1.4. Example. There are also cosmological functors connecting the $\infty$-cosmoi of fibrant inverse diagrams.

(i) By Proposition 6.1.1, the domain, codomain, and identity functors

$$
\begin{array}{c}
\mathcal{K}^\circ \leftarrow \text{id} \rightarrow \mathcal{K} \\
\downarrow \text{dom} & & \downarrow \text{cod}
\end{array}
$$

are all cosmological.

(ii) By Exercise 8.1.i, the domain and left and right codomain functors

$$
\begin{array}{c}
\mathcal{K}^\times \leftarrow \text{dom} \rightarrow \mathcal{K} \\
\downarrow \text{l-cod} & & \downarrow \text{r-cod}
\end{array}
$$

from the $\infty$-cosmos of two-sided isofibrations are cosmological.

To wrap up this section, we establish a suite of results that demonstrate that cosmological functors preserve many of the $\infty$-categorical notions we have thus far encountered, surveying also the results along this line that have previously been established. There is one subtlety that we must contend with when considering cosmological functors that are not necessarily biequivalences, namely that cosmological functors may fail dramatically to be surjective on objects — $\text{id} : \mathcal{K} \to \mathcal{K}^\circ$ comes to mind. Thus a 2-categorical property involving a universal quantifier is not obviously preserved. For instance, by Definition 1.2.26 an object $E \in \mathcal{K}$ is discrete just when for all $X \in \mathcal{K}$, $\text{Fun}(X, E)$ is a Kan complex. However, by Lemma 1.2.27, discrete objects admit an internal characterization as those $\infty$-categories for which the isofibration $E^\otimes \to E^2$ is a trivial fibration. Since cosmological functors preserve trivial
fibrations and simplicial cotensors, we easily conclude that cosmological functors preserve discrete \(\infty\)-categories.

Importantly:

10.1.5. PROPOSITION. Cosmological functors preserve comma \(\infty\)-categories: if \(F: \mathcal{K} \to \mathcal{L}\) is a cosmological functor and the diagram below-left

\[
\begin{array}{ccc}
E & \xleftarrow{e_1} & B \\
\downarrow{e} & \Downarrow{\phi} & \Downarrow{\psi} \\
C & \xleftarrow{f} & A
\end{array}
\quad \sim 
\begin{array}{ccc}
F \circ E & \xleftarrow{F \circ e_1} & F \circ B \\
\downarrow{F \circ e} & \Downarrow{F \circ \phi} & \Downarrow{F \circ \psi} \\
F \circ C & \xleftarrow{F \circ f} & F \circ A
\end{array}
\tag{10.1.6}
\]

is a comma cone in \(\mathcal{K}\), then the diagram above-right is a comma cone in \(\mathcal{L}\).

**Proof.** The simplicial pullback (3.4.2) that constructs the comma cone is preserved by any cosmological functor. By Proposition 3.4.11, any comma cone as above left arises from a fibered equivalence \(\square e: E \cong Hom_A(f,g)\) where \(e = \phi \varepsilon\), and any fibered equivalence of this form defines a comma cone. Since \(F \circ \square e: F \circ E \cong F(Hom_A(f,g)) \cong Hom_{F \circ A}(Ff,Fg)\), we conclude that the right-hand data again defines a comma cone. \(\square\)

Using Proposition 10.1.5, we can quickly establish the following preservation properties of cosmological functors by arguing along similar lines as for discrete \(\infty\)-categories. For ease of reference, we include on this list the preservation properties that have been previously established.

10.1.7. PROPOSITION. Cosmological functors preserve:

(i) Equivalences between \(\infty\)-categories.
(ii) Adjunctions between \(\infty\)-categories, including right adjoint right inverse adjunctions and left adjoint right inverse adjunctions.
(iii) Invertible 2-cells and mates.
(iv) Trivial fibrations and discrete \(\infty\)-categories.
(v) Flexible weighted limits.
(vi) Comma spans and comma cones.
(vii) Absolute right and left lifting diagrams.
(viii) Limits or colimits of diagrams indexed by a simplicial set \(J\) inside an \(\infty\)-category.
(ix) Cartesian and cocartesian fibrations and cartesian functors between them.
(x) Discrete cartesian fibrations and discrete cocartesian fibrations.
(xi) Two-sided fibrations and cartesian functors between them.
(xii) Modules and represented modules.

**Proof.** Lemma 1.3.2 proves that cosmological functors preserve equivalences between \(\infty\)-categories since these can be characterized as 2-categorical equivalences, which are preserved by any 2-functor. Similarly, as observed in Lemma 2.1.3, adjunctions are preserved by any 2-functor, as are invertible 2-cells and mates. So the preservation properties (i),(ii), and(iii) hold under much weaker hypotheses.

The preservation of trivial fibrations was also established in Lemma 1.3.2 and the preservation of discrete \(\infty\)-categories follows using Lemma 1.2.27, proving (iv). Proposition 6.3.1(i) proves that cosmological functors preserve all flexible weighted limits as stated in (v). Proposition 10.1.5 proves that cosmological functors preserve comma spans in the \(\infty\)-cosmos and comma cones in the homotopy 2-category as stated in (vi).
The preservation property (vii), first observed in Corollary 3.5.7, follows from Theorem 3.5.3, which characterizes absolute lifting diagrams as fibered equivalences of comma $\infty$-categories, Proposition 10.1.5, which says that cosmological functors preserve commas, and the fact that cosmological functors preserve equivalences. Now (viii) follows from this by Definition 2.3.7 and the fact that cosmological functors preserve simplicial tensors.

The preservation properties (ix) and (x) also follow from Proposition 10.1.5 and the fact that cosmological functors preserve right or left adjoint right inverse adjunctions, mates, and trivial fibrations via the characterizations of Theorem 5.2.10(iii), Theorem 5.3.4(iii), and Proposition 5.6.8. More details are given in the proof of Corollary 5.2.15, which also observes that cartesian natural transformations are preserved by cosmological functors.

Directly from the internal characterization of Theorem 7.1.4 and the preservation of adjunctions and invertible 2-cells, cartesian functors preserve two-sided fibrations and cartesian functors between them, as observed in Corollary 7.1.9. This establishes (xi). By Proposition 1.3.3(vi), a cosmological functor induces a direct image cosmological functor between sliced $\infty$-cosmoi, which then preserves discrete objects by (iv). Thus, modules are also preserved. By specializing Proposition 10.1.5 to cospans involving identities, it becomes clear that left and right representable commas are preserved. Since a module is representable if and only if it is fibered equivalent to one of these, representable modules are preserved as well, completing the proof of (xii).

10.1.8. NON-EXAMPLE. The composite of the underlying quasi-category functor with the homotopy category functor

$$\mathcal{K} \xrightarrow{(-)_0} Q\text{Cat} \xrightarrow{h} \text{Cat}$$

defines a simplicial functor that carries an $\infty$-category $A$ to its homotopy category $hA$ first introduced in Definition 1.4.12. This functor does preserve isofibrations but does not preserve simplicial cotensors and so is not cosmological. This is a good thing because if it were Proposition 10.1.7(viii) would imply that limits in an $\infty$-category would also define limits in its homotopy category, which is not generally true.

10.1.9. WARNING. Conspicuously missing from the list of $\infty$-categorical structures that are preserved by cosmological functors are composites in the virtual equipment of modules and then a variety of further structures that were defined in reference to this notion: exact squares, pointwise right and left extensions, and (weighted) limits and colimits of $\infty$-category indexed diagrams.

There are a number of factors that contribute to the failure of composites and strong composites to be preserved by cosmological functors in general. One immediate issue is presented by the universal properties given in Definitions 8.3.1 and 8.3.5, which each involve universal quantifiers. As cosmological functors need not be essentially surjective, a universal quantifier in the domain need not scope over the codomain.

In other contexts, universal quantifiers are done away with by means of an “internal characterization” of the $\infty$-categorical notion, but no such characterization is given in this case. At issue is the fact that the composite module should be understood as defined using a “pullback stable fiberwise coinverter,” reflecting the two-sided fibration formed by the composite of the spans into discrete two-sided fibrations. We haven't presented such a construction because our axiomatic notion of $\infty$-cosmos does not include colimits, but even if it did—and Appendix E reveals that homotopy colimits of $\infty$-categories are often present in examples—cosmological functors, being “right-adjoint like” would not preserve them.
That said, any strong composites that are obtained by applying Lemma 8.3.7 are preserved by cosmological functors, since fibered adjunctions are preserved. This includes all of the formally-defined composites established in §8.3 and §8.4. Similar remarks apply to exact squares. Because generic composites are not preserved by cosmological functors, generic exact squares need not be preserved either. But the formally-defined exact squares established in §9.2 are preserved by cosmological functors. For instance, Lemma 9.2.6 proves that comma squares are exact squares in any $\infty$-cosmos. Since cosmological functors preserve comma square, this class of exact squares is then preserved.

As we shall discover, cosmological biequivalences do preserve all of these $\infty$-categorical notions, as well as reflect and create them. It is to this subject that we now turn.

**Exercises.**

10.1.i. **Exercise.** Argue that any cosmological functor $F: \mathcal{K} \to \mathcal{L}$ induces a cosmological functor $F: _{A/F_{\mathcal{Fib}(\mathcal{K})}}^{\mathcal{Fib}(\mathcal{K})} \to _{FA/F_{\mathcal{Fib}(\mathcal{L})}}^{\mathcal{Fib}(\mathcal{L})}$ for each pair of $\infty$-categories $A$ and $B$ in $\mathcal{K}$.

10.1.ii. **Exercise.** Exercise 6.4.v shows that cosmological embeddings reflect discrete $\infty$-categories in addition to preserving them. What other $\infty$-categorical properties are reflected or created by cosmological embeddings?

### 10.2. Cosmological Biequivalences

Special cosmological functors, called biequivalences, preserve and also reflect the category theory developed in this text. Recall from Definition 1.3.6 that a cosmological biequivalence is a cosmological functor $F: \mathcal{K} \to \mathcal{L}$ that is

- surjective on objects up to equivalence: for all $C \in \mathcal{L}$ there exists $A \in \mathcal{K}$ so that $FA \simeq C$; and
- a local equivalence of quasi-categories: for every pair $A,B \in \mathcal{K}$, the map
  $$\text{Fun}(A,B) \to \text{Fun}(FA,FB)$$

is an equivalence of quasi-categories.

Two $\infty$-cosmoi are **biequivalent** if there exists a finite zig-zag of biequivalences connecting them.

#### 10.2.1. Example (biequivalences between $\infty$-cosmoi of $(\infty,1)$-categories)

In §E.2, we show that the functors (10.0.1) are all biequivalences. Except for the functor $\sharp: \mathcal{Q}Cat \to 1\text{-Comp}$, each of the functors (10.0.1) arises from a simplicially enriched right Quillen equivalence between model categories enriched over the Joyal model structure with all objects cofibrant. Corollary E.1.2 demonstrates that any functor of this form encodes a cosmological biequivalence.

Recall that any $\infty$-cosmos has an **underlying quasi-category functor**

$$\mathcal{K} \xrightarrow{(-)_0=\text{Fun}(1,-)} \mathcal{Q}Cat$$

defined by mapping out of the terminal $\infty$-category. We now show that the underlying quasi-category functor of any $\infty$-cosmos that is biequivalent to $\mathcal{Q}Cat$ is a cosmological biequivalence. This justifies the definition of $\infty$-cosmos of $(\infty,1)$-categories given in §1.3.

#### 10.2.2. Proposition

If an $\infty$-cosmos $\mathcal{K}$ is biequivalent to $\mathcal{Q}Cat$, then the underlying quasi-category functor $(-)_0: \mathcal{K} \to \mathcal{Q}Cat$ is a cosmological biequivalence.
Proof. We will show that in the presence of cosmological biequivalences

\[
\mathcal{K} \leftarrow \mathcal{L} \xrightarrow{F} \mathcal{QC} \xrightarrow{G} \mathcal{Q} \xrightarrow{\sim} \mathcal{Q} \xrightarrow{Q} \mathcal{QC} \xrightarrow{\sim} \mathcal{L} \xrightarrow{\sim} \mathcal{K}
\]

the underlying quasi-category functor \((-)_0: \mathcal{K} \to \mathcal{QC}\) is a cosmological biequivalence. Note this formulation includes the special cases where one of the functors \(F\) or \(G\) is an identity. By induction, the same conclusion holds for any \(\mathcal{Q}\)-cosmos connected by a finite zig-zag of biequivalences to \(\mathcal{QC}\).

As \(F\) is a biequivalence, for each quasi-category \(\mathcal{Q}\), there exists an \(\mathcal{Q}\)-category \(\mathcal{B} \in \mathcal{L}\) so that \(FB \cong Q\). Because \(F\) and \(G\) are both local equivalences preserving the terminal \(\mathcal{Q}\)-category \(1\)—for which we adopt the same notation in each of \(\mathcal{K}, \mathcal{L},\) and \(\mathcal{QC}\)—there is then a zig-zag of equivalences of quasi-categories

\[
(GB)_0 = \text{Fun}(1, GB) \xrightarrow{\sim} \text{Fun}(1, B) \xrightarrow{\sim} \text{Fun}(1, FB) \cong FB \cong Q.
\]

This proves that there exists an \(\mathcal{Q}\)-category \(GB \in \mathcal{K}\) whose underlying quasi-category is equivalent to \(Q\).

To show that the underlying quasi-category functor \((-)_0: \mathcal{K} \to \mathcal{QC}\) is a local equivalence, consider a pair of \(\mathcal{Q}\)-categories \(A, B \in \mathcal{K}\). By essential surjectivity of \(G\), there exist \(\mathcal{Q}\)-categories \(X, Y \in \mathcal{L}\) so that \(GX \cong A\) and \(B \congGY\). By pre- and post-composing with these equivalences, Corollary 1.4.9 implies that \(\text{Fun}(A, B) \to \text{Fun}(A_0, B_0)\) is equivalent to \(\text{Fun}(GX, GY) \to \text{Fun}((GX)_0, (GY)_0)\), so it suffices to prove that the latter map is an equivalence of quasi-categories.

By simplicial functoriality—see Definition A.2.5—the actions on functor spaces of \(F\) and \(G\) commutes with the composition map

\[
\text{Fun}(X, Y) \times \text{Fun}(1, X) \xrightarrow{\circ} \text{Fun}(1, Y)
\]

which transposes to define the action on functor spaces of the underlying quasi-category functor. Thus, there is a commutative diagram whose vertical maps are equivalences

\[
\begin{array}{ccc}
\text{Fun}(GX, GY) & \xrightarrow{\sim} & \text{Fun}(1, GX, \text{Fun}(1, GY)) \\
\uparrow & & \downarrow \\
\text{Fun}(X, Y) & \xrightarrow{\sim} & \text{Fun}(1, X, \text{Fun}(1, Y)) \\
\uparrow & & \downarrow \\
\text{Fun}(FX, FY) & \xrightarrow{\sim} & \text{Fun}(1, FX, \text{Fun}(1, FY)) \\
\end{array}
\]

Any quasi-category is isomorphic to its underlying quasi-category, so the bottom horizontal map is an isomorphism. By the 2-of-3 property, it follows that the top horizontal map is an equivalence, which is what we wanted to show. \(\square\)

Recall from Proposition 1.3.3(vi) that a cosmological functor \(F: \mathcal{K} \to \mathcal{L}\) induces a cosmological functor \(F: \mathcal{K}_B \to \mathcal{L}_{FB}\) for any \(B \in \mathcal{K}\).

10.2.3. Proposition. If \(F: \mathcal{K} \Rightarrow \mathcal{L}\) is a cosmological biequivalence, then for any \(B \in \mathcal{K}\) the induced functor \(F: \mathcal{K}_B \Rightarrow \mathcal{L}_{FB}\) is also a cosmological biequivalence.
Proof. We first argue that the $F$ defines a local equivalence of sliced mapping quasi-categories, as defined in Proposition 1.2.22(ii). Given a pair of isofibration $p: E \to B$ and $p': E' \to B$ in $\mathcal{K}$, the induced functor on mapping quasi-categories is defined by

$$
\begin{align*}
\text{Fun}_B(p, p') &\quad \to \quad \text{Fun}(E, E') \\
\text{Fun}_{F\mathcal{B}}(Fp, Fp') &\quad \to \quad \text{Fun}(FE, FE') \\
1 &\quad \to \quad \text{Fun}(E, B) \\
1 &\quad \to \quad \text{Fun}(FE, FB)
\end{align*}
$$

As the maps between the cospans in $\mathcal{QC}at$ are equivalences, by Proposition 3.3.3 so is the induced map between the pullbacks.

For surjectivity up to equivalence, consider an isofibration $q: L \to FB$ in $\mathcal{L}$. As $F$ is surjective on objects up to equivalence, there exists some $A \in \mathcal{K}$ together with an equivalence $i: FA \Rightarrow L \in \mathcal{L}$. As $F$ defines a local equivalence of mapping quasi-categories, there is moreover a functor $f: A \to B$ in $\mathcal{L}$ so that $Ff: FA \to FB$ is naturally isomorphic to $qi$; see Exercise 3.3.1. The map $f$ need not be an isofibration, but Lemma 1.2.16 allows us to factor $f$ as $A \Rightarrow K \Rightarrow B$. Choosing an equivalence inverse $j: K \Rightarrow A$, this data defines a diagram in $b\mathcal{L}$ that commutes up to isomorphism:

$$
\begin{align*}
F\mathcal{K} &\quad \xrightarrow{Fj} \quad FA \quad \xrightarrow{i} \quad L \\
Fp &\quad \cong \quad Ff \quad \cong \quad iFj \\
FB &\quad \cong \quad q
\end{align*}
$$

Proposition 1.4.10 tells us that isofibrations in $\infty$-cosmoi define isofibrations in the homotopy 2-category. In particular, we may lift the displayed isomorphism along the isofibration $q: L \to FB$ to define a commutative triangle:

$$
\begin{align*}
F\mathcal{K} &\quad \xrightarrow{Fj} \quad FA \quad \xrightarrow{i} \quad L \\
Fp &\quad \cong \quad Ff \quad \cong \quad q \\
FB &\quad \cong \quad e \\
\end{align*}
$$

By Exercise 1.4.iv, since $e$ is isomorphic to an equivalence $i \cdot Fj$, it must also define an equivalence. Thus, by Proposition 1.2.22(vii), we have shown that the isofibration $p': K \to B$ maps under $F$ to an isofibration that is equivalent to our chosen $q: L \to FB$. □

A similar argument proves that a cosmological biequivalence induces a biequivalence between the corresponding $\infty$-cosmoi of isofibrations of Proposition 6.1.1.

10.2.4. Proposition. If $F: \mathcal{K} \Rightarrow \mathcal{L}$ is a cosmological biequivalence then the induced functor $F: \mathcal{K}\downarrow \Rightarrow \mathcal{L}\downarrow$ is a biequivalence.

Proof. Exercise 10.2.ii. □

We establish another family of biequivalences of sliced $\infty$-cosmoi:
10.2.5. **Proposition.** If \( f : A \rightarrow B \) is an equivalence in \( \mathcal{K} \), then the pullback functor \( f^* : \mathcal{K}_B \rightarrow \mathcal{K}_A \) is a cosmological biequivalence.

**Proof.** To see that \( f^* : \mathcal{K}_B \rightarrow \mathcal{K}_A \) is essentially surjective, consider an object \( r : D \rightarrow A \). Factor the composite map \( fr : D \rightarrow B \) as an equivalence followed by an isofibration, and pull the result back along \( f \).

![Diagram]

By Proposition 3.3.2, the pullback of \( f \) is an equivalence, so by the 2-of-3 property, \( r \) is equivalent to the isofibration \( q : P \rightarrow A \), which is in the image of \( f^* : \mathcal{K}_B \rightarrow \mathcal{K}_A \).

To show that this simplicial functor is a local equivalence, consider a pair of isofibrations \( p : E \rightarrow B \) and \( q : F \rightarrow B \). We will show that the quasi-category of functors over \( B \) is equivalent to the quasi-category of functors over \( A \) between their pullbacks

\[
\begin{array}{ccc}
 f^*E & \xrightarrow{h} & E \\
 \downarrow & & \downarrow p \\
 A & \xrightarrow{f} & B
\end{array}
\]

To define the comparison map \( \text{Fun}_B(E,F) \rightarrow \text{Fun}_A(f^*E,f^*F) \) consider the following commutative prism

\[
\begin{array}{ccccccc}
 \text{Fun}_B(E,F) & \xrightarrow{s} & \text{Fun}(f^*E,F) & \xrightarrow{k} & \text{Fun}(f^*E,F) & \xrightarrow{q} & \text{Fun}(E,F) \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 \text{Fun}_A(f^*E,f^*F) & \xrightarrow{ad} & \text{Fun}(f^*E,f^*F) & \xrightarrow{ad} & \text{Fun}(f^*E,F) & \xrightarrow{ad} & \text{Fun}(E,B) \\
 \downarrow & & \downarrow s & & \downarrow p & & \downarrow q \\
 \mathbb{1} & \xrightarrow{r} & \text{Fun}(f^*E,A) & \xrightarrow{f^*} & \text{Fun}(f^*E,B) & & \text{Fun}(E,B)
\end{array}
\]

The front-right square is a pullback by the simplicial universal property of \( f^*F \), while the front-left square and back face are the pullbacks that define \( \text{Fun}_A(f^*E,f^*F) \) and \( \text{Fun}_B(E,F) \). The universal property of the composite front pullback rectangle induces the map \( \text{Fun}_B(E,F) \rightarrow \text{Fun}_A(f^*E,f^*F) \). As this functor is the pullback of the equivalences \( h^* \) of Corollary 1.4.9, by Proposition 3.3.3 the induced map defines an equivalence of quasi-categories.

Further induced cosmological biequivalences arise by application of the following lemma, which revisits the setting of Proposition 6.4.3, a result used to construct cosmologically embedded \( \infty \)-cosmoi. We leave its applications to the exercises and return to this topic in Corollary 10.3.7.
10.2.6. **Lemma.** Consider a pullback diagram of $\infty$-cosmoi and cosmological functors

\[
\begin{array}{c}
\mathcal{K} \\
\downarrow F \\
\mathcal{K} \end{array}
\quad
\begin{array}{c}
\mathcal{L}' \\
\downarrow \sim \\
\mathcal{L} \end{array}
\]

in which $F : \mathcal{K} \Rightarrow \mathcal{L}$ is a cosmological biequivalence and $\mathcal{L}' \hookrightarrow \mathcal{L}$ and $\mathcal{K} \hookrightarrow \mathcal{K}$ are cosmological embeddings.¹ Then $F : \mathcal{K}' \Rightarrow \mathcal{L}'$ is a cosmological biequivalence.

**Proof.** The essential point is the repleteness of the cosmological embedding $\mathcal{L}' \hookrightarrow \mathcal{L}$ enumerated in Definition 6.4.1. To see that $F : \mathcal{K}' \rightarrow \mathcal{L}'$ is essentially surjective, consider an $\infty$-category $L \in \mathcal{L}'$. By essential surjectivity of the cosmological biequivalence $F : \mathcal{K} \Rightarrow \mathcal{L}$ there exists an $\infty$-category $K \in \mathcal{K}$ so that $FK \approx L$ in $\mathcal{L}$. By repleteness of $\mathcal{L}' \hookrightarrow \mathcal{L}$, the equivalence $FK \hookrightarrow L$ also lies in $\mathcal{L}'$ and hence $K$ lies in the pullback $\mathcal{K}'$ and maps via $F$ to an object equivalent to $L$ in $\mathcal{L}'$.

For the local equivalence, the induced mappings on functor spaces associated to a pair of $\infty$-categories $A$ and $B$ in $\mathcal{K}'$ form a pullback of quasi-categories

\[
\begin{array}{c}
\text{Fun}_{\mathcal{K}'}(A, B) \\
\downarrow F \\
\text{Fun}_{\mathcal{K}}(A, B) \end{array}
\quad
\begin{array}{c}
\text{Fun}_{\mathcal{L}'}(FA, FB) \\
\downarrow \sim \\
\text{Fun}_{\mathcal{L}}(FA, FB) \end{array}
\]

By Exercise 6.4.i, the vertical functors are isofibrations between quasi-categories. Thus, by Proposition 3.3.2, the local equivalence of $F : \mathcal{K} \rightarrow \mathcal{L}$ pulls back to define a local equivalence for $F : \mathcal{K}' \rightarrow \mathcal{L}'$. So we conclude that the restricted functor remains a cosmological biequivalence. □

**Exercises.**

10.2.i. **Exercise (10.3.1).** Show that an equivalence of quasi-categories $f : K \Rightarrow L$ induces a bijection on isomorphism classes of vertices, i.e., a bijection on isomorphism classes of objects in the homotopy categories of $K$ and $L$. Conclude that for any cosmological biequivalence $F : \mathcal{K} \Rightarrow \mathcal{L}$ and any pair of $\infty$-categories $A, B \in \mathcal{K}$

(i) For any functor $f' : FA \rightarrow FB$ there exists a functor $f : A \rightarrow B$ and a natural isomorphism $Ff \approx f'$ in $\mathcal{L}$.

(ii) If $f, g : A \rightarrow B$ are functors so that $Ff \approx Fg$ in $\mathcal{L}$ then $f \equiv g$ in $\mathcal{K}$.

10.2.ii. **Exercise.** Prove Proposition 10.2.4.

10.2.iii. **Exercise.** If $F : \mathcal{K} \Rightarrow \mathcal{L}$ is a biequivalence and $A \in \mathcal{K}$ and $B \in \mathcal{L}$ are so that $FA \approx B$ prove that the slice $\infty$-cosmoi $\mathcal{K}|_A$ and $\mathcal{L}|_B$ are biequivalent.

10.2.iv. **Exercise (10.3.7).** Explore the applicability of Lemma 10.2.6 to the task of verifying that the $\infty$-cosmoi constructed in §6.4 are biequivalence-invariant.

¹If the $\infty$-cosmos structure on $\mathcal{K}'$ is created by this pullback, then $\mathcal{K}' \hookrightarrow \mathcal{K}$ is automatically a cosmological embedding and the functor $\mathcal{K}' \rightarrow \mathcal{L}'$ is automatically cosmological; see Proposition 6.4.3.
10.3. Cosmological Biequivalences as Change-of-Model Functors

We refer to biequivalence between $\infty$-cosmoi as change-of-model functors. In this section, we enumerate their basic properties. First, we observe that cosmological biequivalences descend to biequivalences between homotopy 2-categories, hence the name:

10.3.1. Proposition. A cosmological biequivalence $F: \mathcal{K} \Rightarrow \mathcal{L}$ induces a biequivalence $\mathfrak{h}\mathcal{K} \Rightarrow \mathfrak{h}\mathcal{L}$ of homotopy 2-categories: i.e., the 2-functor $F$ is

(i) surjective on objects up to equivalence and

(ii) defines a local equivalence of categories $\mathfrak{h}\text{Fun}(A, B) \Rightarrow \mathfrak{h}\text{Fun}(FA, FB)$ for all $A, B \in \mathcal{K}$.

Note that the local equivalences of (ii) necessarily have the properties enumerated in Exercise 10.2.i.

Proof. This is immediate from the definition: Theorem 1.4.7 observed that $\infty$-cosmos-level equivalences coincide with 2-categorical equivalences, and by Lemma 1.2.18 the homotopy category functor $h: \mathcal{QC}\text{at} \to \mathcal{C}\text{at}$ carries equivalences of quasi-categories to equivalences of categories. □

In particular, recalling Definition 1.4.12, it follows immediately that for every $\infty$-category $A \in \mathcal{K}$, that the biequivalence $F$ induces an equivalence of homotopy categories $hA \Rightarrow hFA$: see Exercise 10.3.i. Thus, the homotopy category of an $\infty$-category is invariant under change of model.

Any biequivalence between 2-categories induces a variety of local and global bijections, as enumerated below, which can be put to use to solve Exercise 10.3.iii.

10.3.2. Corollary. Consider any cosmological biequivalence $F: \mathcal{K} \Rightarrow \mathcal{L}$.

(i) The biequivalence $F$ preserves, reflects, and creates equivalences between $\infty$-categories, and induces a bijection between equivalence classes of objects.

(ii) The biequivalence $F$ induces local bijections between isomorphism classes of functors extending the bijection of (i): choosing any pairs of objects $A, B \in \mathcal{K}$ and $A', B' \in \mathcal{L}$ and equivalences $a: A' \Rightarrow FA$ and $b: FB \Rightarrow B'$, the map

$$h\text{Fun}(A, B) \Rightarrow h\text{Fun}(FA, FB) \Rightarrow h\text{Fun}(A', B')$$

defines a bijection between isomorphism classes of functors $A \to B$ in $\mathcal{K}$ and isomorphism classes of functors $A' \to B'$ in $\mathcal{L}$.

(iii) The biequivalence $F$ induces local bijections between 2-cells with specified boundary extending the bijections of (i) and (ii): choosing any pairs of objects $A, B \in \mathcal{K}$ and $A', B' \in \mathcal{L}$, specified equivalences $a: A' \Rightarrow FA$ and $b: FB \Rightarrow B'$, functors $f, g: A \to B$ and $f', g': A' \to B'$, and natural isomorphisms

$$
\begin{align*}
& FA \xrightarrow{Ff} FB & FA \xrightarrow{Fg} FB \\
& \downarrow a \quad \equiv a & \downarrow a \quad \equiv a \\
& \Rightarrow b & \Rightarrow b \\
& A' \xrightarrow{f'} B' & A' \xrightarrow{g'} B'
\end{align*}
$$

the map (10.3.3) induces a bijection between 2-cells $f \Rightarrow g$ in $\mathcal{K}$ and 2-cells $f' \Rightarrow g'$ in $\mathcal{L}$.

Proof. For (i), any 2-functor preserves equivalences, so our first take is to show that equivalences are also reflected. If $f: A \to B$ is a morphism so that $Ff: FA \Rightarrow FB$ is an equivalence then by the
2-of-3 property and the commutative diagram

\[
\begin{array}{ccc}
\text{Fun}(X, A) & \xrightarrow{f_*} & \text{Fun}(X, B) \\
\downarrow & & \downarrow \\
\text{Fun}(FX, FA) & \xrightarrow{Ff_*} & \text{Fun}(FX, FB)
\end{array}
\]

\(f_*\) is an equivalence for all \(X\), proving that \(f: A \to B\) is an equivalence.

To prove that equivalences are also created — meaning that if \(FA \simeq FB\) then \(A \simeq B\) — note that the equivalence \(h\text{Fun}(A, B) \to h\text{Fun}(FA, FB)\) implies that any morphism \(FA \to FB\) has a lift \(A \to B\) up to isomorphism. In this way, the morphisms of an equivalence \(f: FA \Rightarrow FB\) and \(g: FB \Rightarrow FA\) can be lifted to morphisms \(\tilde{f}: A \to B\) and \(\tilde{g}: B \to A\) so that \(\tilde{g}\tilde{f}\) and \(\text{id}_A\) have isomorphic images under the equivalence \(h\text{Fun}(A, A) \Rightarrow h\text{Fun}(FA, FA)\). Since an equivalence of quasi-categories induces a bijection on isomorphism classes of vertices, we conclude that \(\tilde{g}\tilde{f} \cong \text{id}_A \in h\text{Fun}(A, A)\). Similarly, \(\tilde{f}\tilde{g}\) and \(\text{id}_B\) have isomorphic images under \(h\text{Fun}(B, B) \Rightarrow h\text{Fun}(FB, FB)\) and thus \(\tilde{f}\tilde{g} \cong \text{id}_B\), proving that \(A \simeq B\).

Finally, the preservation, reflection, and creation of equivalences together with essential surjectivity of a cosmological biequivalence implies that such functors induces a bijection on equivalence classes of objects.

For (ii), by Corollary 1.4.9, the chosen equivalences \(FA \simeq A'\) and \(FB \simeq B'\) induce an equivalence of quasi-categories

\[
\begin{array}{ccc}
\text{Fun}(A, B) & \xrightarrow{\sim} & \text{Fun}(FA, FB) \\
& & \xrightarrow{\sim} \text{Fun}(A', B')
\end{array}
\]

which descends to the equivalence of homotopy categories (10.3.3). Since equivalences of quasi-categories induce bijections between isomorphism classes of vertices, this yields in particular a bijection between isomorphism classes of functors.

For (iii), the equivalence (10.3.3) is full and faithful, inducing a bijection between cells \(f \Rightarrow g\) and \(b \cdot Ff \cdot a \Rightarrow b \cdot Fg \cdot a\). This bijection can be transported along any chosen isomorphisms \(\alpha\) and \(\beta\) to yield a bijection between natural transformations \(f \Rightarrow g\) in \(h\text{Fun}(A, B)\) in \(\mathcal{K}\) and natural transformations \(f' \Rightarrow g'\) in \(h\text{Fun}(A', B')\) in \(\mathcal{L}\).

As an application of Corollary 10.3.2, we now fulfill a promise made in §2.3, establishing an equivalence between the internal hom \(B^A\) between \(\infty\)-categories \(A\) and \(B\) in an \(\infty\)-cosmos of \((\infty, 1)\)-categories and the simplicial cotensor \(B^{A_0}\) of \(B\) with the underlying quasi-category of \(A\). At first blush, it might seem that we would need to add the hypothesis that the \(\infty\)-cosmos of \((\infty, 1)\)-categories is cartesian closed, but in fact we can make do without this hypothesis.

10.3.4. Observation. In an \(\infty\)-cosmos of \((\infty, 1)\)-categories \(\mathcal{K}\), even if \(\mathcal{K}\) is not cartesian closed as an \(\infty\)-cosmos in the sense of Definition 1.2.23, its homotopy 2-category \(h\mathcal{K}\) is cartesian closed in the bicategorical sense, replacing the natural equivalences of Proposition 1.4.5(ii) with natural equivalences.

On account of the biequivalence \((-)_0: \mathcal{K} \Rightarrow \text{QCat}\) of Proposition 10.2.2, we define \(B^A \in \mathcal{K}\) to be any
∞-category whose underlying quasi-category is equivalent to $B_{0}^{A_{0}}$. By composing equivalences

$$
\begin{array}{c}
\text{Fun}(X, B^{A}) \xrightarrow{\sim} \text{Fun}(X_{0}, B_{0}^{A_{0}}) \\
\downarrow \cong \\
\text{Fun}(X \times A, B) \xrightarrow{\sim} \text{Fun}(X_{0} \times A_{0}, B_{0})
\end{array}
$$

we see that $\text{Fun}(X, B^{A}) \cong \text{Fun}(X \times A, B)$ for any $X$. In terminology to be introduced in §10.4, the map $\text{Fun}(X, B^{A}) \Rightarrow \text{Fun}(X \times A, B)$ is a quasi-pseudonatural equivalence. Note that if $\mathcal{K}$ is cartesian closed, this universal property demonstrates that the weak exponentials are equivalent to the strictly-defined ones.

For this reason, the statement of Proposition 10.3.5 does not require that the ambient ∞-cosmos is cartesian closed; the exponentials can be inferred to exist a posteriori.

10.3.5. PROPOSITION. For any ∞-categories $A$ and $B$ in an ∞-cosmos of (∞, 1)-categories, the exponential $B^{A} \cong B_{0}^{A_{0}}$ is equivalent to the cotensor of $B$ with the underlying quasi-category of $A$.

PROOF. By Corollary 10.3.2(i), cosmological biequivalences reflect equivalences of ∞-categories. Thus, to prove $B^{A} \cong B_{0}^{A_{0}}$, it suffices by Proposition 10.2.2 and Corollary 10.3.2 to prove that $B^{A}$ and $B_{0}^{A_{0}}$ have equivalent underlying quasi-categories. The defining universal properties of the exponential and cotensor provide equivalences

$$
\text{Fun}(1, B^{A}) \cong \text{Fun}(A, B) \xrightarrow{\sim} \text{Fun}(A_{0}, B_{0}) \cong \text{Fun}(1, B_{0}^{A_{0}})
$$

which compose with the local equivalence of the underlying quasi-category functor to provide the desired equivalence. □

We now prove that biequivalences reflect and create, as well as preserve, the ∞-categorical structures considered in Section 10.1.

10.3.6. PROPOSITION. A cosmological biequivalence $F: \mathcal{K} \xrightarrow{\sim} \mathcal{L}$

(i) Preserves and reflects the property of a functor defining an equivalence and the invertibility of 2-cells.
(ii) Preserves, reflects, and creates adjunctions between ∞-categories, including right adjoint right inverse adjunctions and left adjoint right inverse adjunctions.
(iii) Preserves and reflects discreteness.
(iv) Preserves, reflects, and creates fibered equivalences.
(v) Preserves and reflects comma and arrow ∞-categories: a cell as on the left of (10.1.6) is a comma cone in $\mathcal{K}$ if and only if its image is a comma cone in $\mathcal{L}$.
(vi) Preserves and reflects cartesian and cocartesian fibrations and cartesian functors between them.
(vii) Preserves and reflects discrete cartesian fibrations and discrete cocartesian fibrations.
(viii) Preserves and reflects two-sided fibrations and cartesian functors between them.
(ix) Preserves and reflects modules and represented modules and induces a bijection on equivalence classes of modules between a fixed pair of ∞-categories.
(x) Preserves, reflects, and creates absolute right and left lifting diagrams over a given cospan.
(xi) Preserves and reflects limits or colimits of diagrams indexed by a simplicial set $J$ inside an ∞-category and creates the property of an ∞-category admitting a limit or colimit of a given diagram.
(xii) Preserves and reflects the stability of an ∞-category and the exactness of functors between such.
Proof. The preservation results are proven in Proposition 10.1.7 under the weaker hypothesis that $F$ is a mere cosmological functor. So it remains only to address reflection and where relevant creation of $\infty$-categorical properties and structures.

Properties (i) and (ii) hold for any biequivalence between 2-categories, such as $F: h\mathcal{K} \simeq h\mathcal{L}$ and are left to Exercise 10.3.iii as a useful exercise to familiarize oneself with the 2-categorical notion of biequivalence.

Property (iii) follows from (i): if $FE$ is discrete, then the image under $F$ of any 2-cell in $\mathcal{K}$ with codomain $E$ is invertible, which implies that that 2-cell is invertible in $E$.

Property (iv) is a special case of Corollary 10.3.2(i) applied to the induced biequivalence of Proposition 10.2.3. Since both $\mathcal{K}$ and $\mathcal{L}$ admit comma $\infty$-categories and Proposition 3.4.11 shows that comma spans are characterized by a fibered equivalence class of two-sided isofibrations, (v) follows from (iv).

Proposition (vi) follows from (ii) and (i) via Theorem 5.2.10, and (vii) follows from Corollary 10.3.2(ii) which shows that equivalence-invertibility of the morphism considered in Proposition 5.6.8 is reflected. Property (viii) follows similarly from Theorem 7.1.4(iii) and (ii) and (i). Preservation and reflection of modules now follows from (iii) and the bijection between equivalence classes follows from (iv). A more precise statement appears as Proposition 11.2.4. The final statement of (ix), on representability, combines (iv) with (v), as elaborated upon in Proposition 11.2.5.

The reflection properties of (x) and (xi) follow from Theorem 3.5.3 and the creation properties follow from Theorem 3.5.12 and (ix). The precise steps are spelled out further in Theorem ??

Finally, (xii) can be argued from any of the equivalent characterizations in Theorem 4.4.12 using (i) and (xi). □

10.3.7. Corollary. If $F: \mathcal{K} \simeq \mathcal{L}$ is a cosmological biequivalence then the following induced cosmological functors are all biequivalences:

1. $F: Disc(\mathcal{K}) \simeq Disc(\mathcal{L})$
2. $F: \mathcal{K}_{T,J} \simeq \mathcal{L}_{T,J}$ and $F: \mathcal{K}_{L,J} \simeq \mathcal{L}_{L,J}$
3. $F: \mathcal{R}ari(\mathcal{K})_B \simeq \mathcal{R}ari(\mathcal{L})_{FB}$ and $F: \mathcal{L}ari(\mathcal{K})_B \simeq \mathcal{L}ari(\mathcal{L})_{FB}$
4. $F: \mathcal{R}ari(\mathcal{K}) \simeq \mathcal{R}ari(\mathcal{L})$ and $F: \mathcal{L}ari(\mathcal{K}) \simeq \mathcal{L}ari(\mathcal{L})$
5. $F: Cart(\mathcal{K})_B \simeq Cart(\mathcal{L})_{FB}$ and $F: coCart(\mathcal{K})_B \simeq coCart(\mathcal{L})_{FB}$
6. $F: Cart(\mathcal{K}) \simeq Cart(\mathcal{L})$ and $F: coCart(\mathcal{K}) \simeq coCart(\mathcal{L})$
7. $F: DiscCart(\mathcal{K}) \simeq DiscCart(\mathcal{L})$ and $F: DisccoCart(\mathcal{K}) \simeq DisccoCart(\mathcal{L})$
8. $F: Stab(\mathcal{K}) \simeq Stab(\mathcal{L})$
9. $F: A\{Fib(\mathcal{K})_B \simeq FA\{Fib(\mathcal{L})_{FB}$
10. $F: A\\{Mod(\mathcal{K})_B \simeq FA\\{Mod(\mathcal{L})_{FB}$

Proof. In each case we start with a cosmological biequivalence — perhaps $\mathcal{K}_B \simeq \mathcal{L}_{FB}$ or $\mathcal{K}^\frac{1}{2} \simeq \mathcal{L}^\frac{1}{2}$ — and must show that the restricted cosmological functor of Lemma 10.1.3 is again a biequivalence between the cosmologically embedded $\infty$-cosmoi. Each of the arguments is similar; for concreteness’ sake, we prove (viii). We know that $F: \mathcal{K} \simeq \mathcal{L}$ induces a bijection between equivalence classes of objects. Since the cosmological embeddings $Stab(\mathcal{K}) \leftrightarrow \mathcal{K}$ and $Stab(\mathcal{L}) \leftrightarrow \mathcal{L}$ are replete, the equivalence classes of $\mathcal{K}$ and $\mathcal{L}$ restricts to define a bijection between equivalence classes of objects in $\mathcal{K}$ and $\mathcal{L}$. Since, moreover, Proposition 10.3.6 proves that the property that characterizes the objects of the sub $\infty$-cosmos is preserved and reflected by any biequivalence, it is clear that the bijection between equivalence classes of objects in $\mathcal{K}$ and $\mathcal{L}$ restricts to define a bijection between equivalence classes of objects in the cosmologically embedded $\infty$-cosmoi. A similar argument shows that the $\infty$-categorical property that characterizes the 0-arrows
in the replete sub ∞-cosmoi is preserved and reflected. Thus, we see that the diagram of cosmological functors

\[
\begin{align*}
\text{Stab}(\mathcal{K}) & \xrightarrow{F} \text{Stab}(\mathcal{L}) \\
\downarrow & \quad \downarrow \\
\mathcal{K} & \xrightarrow{\sim} \mathcal{L}
\end{align*}
\]

is a pullback, so Lemma 10.2.6 allows us to conclude that the induced functor \( F: \text{Stab}(\mathcal{K}) \Rightarrow \text{Stab}(\mathcal{L}) \) is a cosmological biequivalence. □

Warning 10.1.9 mentioned some ∞-categorical properties that are not necessarily preserved by cosmological functors. Importantly, these notions are preserved, reflected, and created by cosmological biequivalences. Lemma 11.2.7 proves this in the case of composites and exact squares, two notions which are situated in the virtual equipment of modules, but we address the case of pointwise right and left extensions now.

10.3.8. Proposition. A cosmological biequivalence \( F: \mathcal{K} \Rightarrow \mathcal{L} \) preserves, reflects, and creates pointwise left and right extensions:

(i) A diagram in \( \mathcal{K} \) of the form

\[
\begin{array}{c}
A \\ \downarrow k
\end{array} \xrightarrow{f} \quad \begin{array}{c}
C \\ \downarrow r
\end{array}
\]

or

\[
\begin{array}{c}
A \\ \downarrow k
\end{array} \xleftarrow{f} \quad \begin{array}{c}
C \\ \downarrow \ell
\end{array}
\]

defines a pointwise right or left extension in \( \mathcal{K} \), respectively, if and only if its image under \( F \) defines, respectively, a pointwise right or left extension in \( \mathcal{L} \).

(ii) If \( f: A \rightarrow C \) and \( k: A \rightarrow B \) are functors in \( \mathcal{K} \) so that \( Ff: FA \rightarrow FC \) admits a pointwise right or left extension along \( Fk: FA \rightarrow FB \) in \( \mathcal{L} \), then \( f \) admits a pointwise right or left extension, respectively, along \( k \) in \( \mathcal{K} \), and its image under \( F \) is isomorphic to the corresponding data in \( \mathcal{L} \).

To explain the idea of the proof, we first show that cosmological biequivalences preserve and reflect right extensions; they create them as well, but in the proof of this is no more complicated in the pointwise case discussed below.

Suppose first that \( \nu: rk \Rightarrow f \) is a right extension in \( \mathcal{K} \). To prove that its image defines a right extension in \( \mathcal{L} \), we must show that for all \( d: FB \rightarrow FC \) the map

\[
h\text{Fun}(FB, FC)(d, Fr) \xrightarrow{F\nu} h\text{Fun}(FA, FC)(d \cdot Fk, Ff)
\]

is a bijection between sets of 2-cells. By Corollary 10.3.2(ii), there exists a functor \( c: B \rightarrow C \) in \( \mathcal{K} \) together with a natural isomorphism \( \delta: d \cong Fc \), By Corollary 10.3.2(iii), application of \( F \) and composition with \( \delta \) defines a bijection

\[
h\text{Fun}(B, C)(c, r) \xrightarrow{F} h\text{Fun}(FB, FC)(Fc, Fr) \xrightarrow{-\delta} h\text{Fun}(FB, FC)(d, Fr)
\]

\[
c \Rightarrow r \quad F \Rightarrow Fr \quad \delta \Rightarrow Fc \Rightarrow Fr
\]
There is a similar bijection defined from the invertible 2-cell \( \delta F k : d \cdot F k \cong F c \cdot F k \). Since \( \nu : r k \Rightarrow f \) is a right extension, composition with \( \nu \) induces its own family of bijections. From the commutative square of functions

\[
\begin{array}{ccc}
\text{hFun}(B, C)(c, r) & \xrightarrow{\nu_{\sim}} & \text{hFun}(A, C)(c \cdot k, f) \\
F_\sim \downarrow & & \downarrow F_\sim \cong \\
\text{hFun}(FB, FC)(d, Fr) & \xrightarrow{F_{\nu_{\sim}}} & \text{hFun}(FA, FC)(d \cdot F k, F f)
\end{array}
\]

three of which are known to be bijections, we see that \( F \nu : Fr \cdot F k \Rightarrow F f \) is a right extension in \( \mathcal{L} \), as claimed.

Now suppose \( F \nu : Fr \cdot F k \Rightarrow F f \) is a right extension in \( \mathcal{L} \). To see that \( \nu : r k \Rightarrow f \) is a right extension in \( \mathcal{K} \), note that for any functor \( c : B \rightarrow C \), there is a commutative square of functions

\[
\begin{array}{ccc}
\text{hFun}(B, C)(c, r) & \xrightarrow{\nu_{\sim}} & \text{hFun}(A, C)(c \cdot k, f) \\
F_\sim \downarrow & & \downarrow F_\sim \\
\text{hFun}(FB, FC)(Fc, Fr) & \xrightarrow{F_{\nu_{\sim}}} & \text{hFun}(FA, FC)(Fc \cdot F k, F f)
\end{array}
\]

three of which are known to be bijections. This proves that \( \nu : r k \Rightarrow f \) has the universal property of a right extension.

The argument for pointwise right extensions is essentially the same, where we additionally make use of the fact that comma \( \infty \)-categories are preserved by cosmological functors and invariant under equivalence, in the sense of Exercise 3.4.iv.

**Proof.** Throughout we use the 2-categorical definition of a pointwise right extension appearing in Theorem 9.3.3(ii). The idea is to take advantage of the local bijections provided by Corollary 10.3.2.

Assume that \( \nu : r k \Rightarrow f \) is a pointwise right extension in \( \mathcal{K} \). We must show that for every \( h : L \rightarrow FB \) in \( \mathcal{L} \) the diagram

\[
\begin{array}{ccc}
\text{Hom}_{FB}(h, Fk) & \xrightarrow{p_1} & FA \\
p_0 \downarrow & & \downarrow Ff \\
L & \xrightarrow{h} & FB
\end{array}
\]

is a right extension diagram in \( \mathcal{L} \), meaning that for all \( d : L \Rightarrow FC \) the map

\[
\begin{array}{ccc}
\text{hFun}(L, FC)(d, Fr \cdot h) & \xrightarrow{F_{p_0} \circ Fr} & \text{hFun}(\text{Hom}_{FB}(h, Fk))(d p_0, Ff \cdot p_1) \\
d \xrightarrow{\zeta} Fr \cdot h & \xrightarrow{\zeta p_0} & d p_0 \Rightarrow Fr \cdot hp_0 \Rightarrow Fr \cdot Fr \cdot p_1 \Rightarrow Ff \cdot p_1
\end{array}
\]

is a bijection between sets of 2-cells. By Corollary 10.3.2(i) there exists an \( \infty \)-category \( K \in \mathcal{K} \) and an equivalence \( e : L \Rightarrow FK \), and by Corollary 10.3.2(ii) there exist functors \( b : K \rightarrow B \) and \( c : K \rightarrow C \) and natural isomorphisms \( \beta : Fb \cdot e \cong h \) and \( \delta : d \cong FC \cdot e \). By Corollary 10.3.2(iii), application of \( F \) and composition with \( e, \beta \), and \( \delta \) defines a bijection

\[
\begin{array}{ccc}
\text{hFun}(K, C)(c, rb) & \xrightarrow{\cong} & \text{Fun}(L, FC)(d, Fr \cdot h) \\
c \xrightarrow{\gamma} rb & \xrightarrow{\delta} & d \xrightarrow{\delta} Fr \cdot Fr \cdot e \Rightarrow Fr \cdot Fr \cdot e \Rightarrow Fr \cdot Fr \cdot e
\end{array}
\]

339
Since $\nu: rk \Rightarrow f$ is a pointwise right extension in $\mathcal{K}$, the diagram

\[ \begin{array}{ccc}
\text{Hom}_B(b, k) & \xrightarrow{p_1} & A \\
p_0 & \downarrow \phi & \downarrow f \\
K & \xrightarrow{b} & B
\end{array} \]

is a (pointwise) right extension as well, defining a bijection

\[ h\text{Fun}(K, C)(c, rb) \xrightarrow{\cong} h\text{Fun}(\text{Hom}_B(b, k), C)(cp_0, fp_1) \]

By Exercise 3.4.iv, there is an equivalence $y: \text{Hom}_{FB}(h, Fk) \cong \text{Hom}_{FB}(Fb, Fk) \cong F\text{Hom}_B(b, k)$ over $e \times \text{id}: L \times F\mathcal{A} \Rightarrow FK \times FA$. By Corollary 10.3.2(iii), application of $F$, composition with $y$, $\beta$, and $\delta$ defines the right-hand bijection in the commutative square of functions

\[ \begin{array}{ccc}
h\text{Fun}(K, C)(c, rb) & \xrightarrow{\cong} & h\text{Fun}(\text{Hom}_B(b, k), C)(cp_0, fp_1) \\
\downarrow & & \downarrow \\
h\text{Fun}(L, FC)(d, Fr \cdot h) & \xrightarrow{\cong} & h\text{Fun}(\text{Hom}_{FB}(h, Fk), FC)(dp_0, Ff \cdot p_1)
\end{array} \]

and thus our pasted diagram in $\mathcal{L}$ is a right extension diagram, as desired.

To see that pointwise right extensions are reflected we must show that (10.3.9) is a right extension diagram in $\mathcal{K}$ under the hypothesis that $F\nu: Fr \cdot Fk \Rightarrow Ff$ is a pointwise right extension diagram in $\mathcal{L}$. For any functor $c: K \rightarrow C$, we have a commutative square of functions:

\[ \begin{array}{ccc}
h\text{Fun}(K, C)(c, rb) & \xrightarrow{\cong} & h\text{Fun}(\text{Hom}_B(b, k), C)(cp_0, fp_1) \\
\downarrow F & & \downarrow F \\
h\text{Fun}(FK, FC)(Fc, Fr \cdot Fb) & \xrightarrow{\cong} & h\text{Fun}(\text{Hom}_{FB}(Fb, Fk), FC)(Fc \cdot p_0, Ff \cdot p_1)
\end{array} \]

Since comma squares are preserved by cosmological functors, the bottom map is a bijection, as our the vertical functions, defined by application of $F$. Thus, $\nu: r \cdot k \Rightarrow f$ satisfies the universal property of a pointwise right extension in $\mathcal{K}$.

Finally, to see that pointwise right extension diagrams are created by cosmological biequivalences suppose we are given a pointwise right extension diagram

\[ \begin{array}{ccc}
FA & \xrightarrow{Ff} & FC \\
\text{Fr} & \xrightarrow{\phi\sigma} & F\mathcal{A} \\
FB & \xrightarrow{s} & Fr \cdot Fb
\end{array} \]

in $\mathcal{L}$. By Corollary 10.3.2, there exists a functor $r: B \rightarrow C$ together with an isomorphism $\alpha: s \cong Fr$ and a natural transformation $\nu: rk \Rightarrow f$ mapping to $\sigma$ under the bijection

\[ \begin{array}{ccc}
h\text{Fun}(A, C)(rk, f) & \xrightarrow{F} & h\text{Fun}(FA, FC)(Fr \cdot Fk, Ff) \\
\xrightarrow{\nu} & & \xrightarrow{s \cdot Fk \Rightarrow Ff} h\text{Fun}(FA, FC)(s \cdot Fk, Ff)
\end{array} \]

340
Since $F
u$ is isomorphic to a pointwise right extension diagram in $\mathcal{L}$ it is a pointwise right extension diagram in $\mathcal{L}$, and since pointwise right extension diagrams are reflected by cosmological biequivalences, $\nu$ exhibits $r$ as a pointwise right extension of $f$ along $k$ as claimed.

Immediately from Definition 9.5.1:

10.3.10. COROLLARY. Cosmological biequivalences preserve, reflect, and create limits and colimits of $\infty$-category indexed diagrams.

Exercises.

10.3.i. EXERCISE. Let $F: \mathcal{K} \Rightarrow \mathcal{L}$ be a cosmological biequivalence. Show, for any $\infty$-category $A \in \mathcal{K}$, that $F$ induces an equivalence of homotopy categories $hA \Rightarrow hFA$.

10.3.ii. EXERCISE.

10.3.iii. EXERCISE. Consider a 2-functor $F: \mathcal{C} \to \mathcal{D}$ that defines a biequivalence in the sense of Proposition 10.3.1. Prove that:

(i) A 2-cell $A \xrightarrow{\alpha} B$ in $\mathcal{C}$ is invertible if and only if $F\alpha$ is invertible in $\mathcal{D}$.

(ii) $u: A \to B$ admits a left adjoint in $\mathcal{C}$ if and only if $Fu: FA \to FB$ admits a left adjoint in $\mathcal{D}$ in which case $F$ preserves the adjunction.

10.3.iv. EXERCISE. Prove that cosmological biequivalences between cartesian closed $\infty$-cosmoi preserve exponential objects up to equivalence.

10.4. Inverse Cosmological Biequivalences

Definition 1.3.6 declares two $\infty$-cosmoi to be biequivalent just when they are connected by a finite zig-zag of cosmological biequivalences. In this section, we establish a few useful properties of the “composite” of such a zig-zag, the analysis of which immediately reduces to the base case: describing the inverse $G: \mathcal{L} \Rightarrow \mathcal{K}$ to a cosmological biequivalence $F: \mathcal{K} \Rightarrow \mathcal{L}$. The definitions introduced here describe the $\infty$-categorical structures that transfer to biequivalent $\infty$-cosmoi, such as the weak exponentials discussed in Observation 10.3.4. The reader might consider skipping this section for now and referring back to it with the applications of Chapter 12 in mind.

To explain what to expect at the level of $(\infty,2)$-categories, consider the analogous 2-categorical case. By Proposition 10.3.1, a cosmological biequivalence $F: \mathcal{K} \Rightarrow \mathcal{L}$ induces a biequivalence $F: h\mathcal{K} \Rightarrow h\mathcal{L}$ of homotopy 2-categories, this being a 2-functor that is

- surjective on objects up to equivalence and
- defines a local equivalence of categories $h\text{Fun}(A,B) \Rightarrow h\text{Fun}(FA,FB)$ for all $A,B \in h\mathcal{K}$.

From these properties we may attempt to define an inverse biequivalence $G$ as follows:

- For each $C \in h\mathcal{L}$, we choose an $A \in h\mathcal{K}$ together with a specified equivalence $\epsilon: FA \simeq C$ and define $GC := A$.
- For each pair $C,D \in h\mathcal{L}$, we define the action of $G$ on hom-categories to be the composite

$$G \approx \text{Fun}(C,D) \xrightarrow{(\epsilon^{-1} \epsilon_{\text{Fun}(F,G)})} \text{Fun}(FGC,FGD) \xrightarrow{F_{GC,GD}^{-1}} \text{Fun}(GC,GD)$$

of the equivalence defined by pre- and post-composing with the maps of the specified equivalences $FGC \simeq C$ and $FGD \simeq D$ together with an inverse of the equivalence defined by the action of $F$. 

341
These choices are suitably unique: the action of $G$ on objects is well-defined up to equivalence and the action of $G$ on hom-categories is well-defined up to natural isomorphism. However, these mappings do not assemble into a 2-functor (see Definition B.2.1): for instance, while the triangle on the left commutes on the nose—expressing the unit axiom for the 2-functor $F$—the composite triangle on the right only commutes up to isomorphism:

\[
\begin{align*}
\text{hFun}(A,A) & \xrightarrow{F_{A,A}} \text{hFun}(FA,FA) \\
\text{hFun}(C,C) & \xrightarrow{(-\circ \eta, \eta \circ -)} \text{hFun}(FGC,FGC) \xrightarrow{F_{GC,GC}^{-1}} \text{hFun}(GC,GC)
\end{align*}
\]

Instead, the mapping $G: h\mathcal{L} \to h\mathcal{K}$ defines a pseudofunctor between the homotopy 2-categories, which we now define. Importantly, the inverse cannot in general be chosen to be a 2-functor; see [69, 3.1].

10.4.1. Definition. A pseudofunctor $G: \mathcal{C} \to \mathcal{D}$ between 2-categories $\mathcal{C}$ and $\mathcal{D}$ is given by:

- a mapping on objects $\mathcal{C} \ni x \mapsto Gx \in \mathcal{D}$;
- a mapping on hom-categories $G_{x,y}: \mathcal{C}(x,y) \to \mathcal{D}(Gx,Gy)$ for each $x, y \in \mathcal{C}$;
- an invertible 2-cell

\[
\begin{array}{ccc}
\text{id}_{Gx} & \cong & \text{id}_{Gx} \\
\text{id}_{X} & \cong & \text{id}_{Gx} \\
C(x,x) & \xrightarrow{t_x \circ} & \mathcal{D}(Gx,Gx)
\end{array}
\]

for each $x \in \mathcal{C}$, defining an isomorphism $t_x: \text{id}_{Gx} \cong G \text{id}_x$ in $\mathcal{D}(Gx,Gx)$; and

- a natural isomorphism

\[
\begin{align*}
\mathcal{C}(y,z) \times \mathcal{C}(x,y) & \xrightarrow{G \times G} \mathcal{D}(Gy,Gz) \times \mathcal{D}(Gx,Gy) \\
\mathcal{C}(x,z) & \xrightarrow{G} \mathcal{D}(Gx,Gz)
\end{align*}
\]

for each triple of objects $x, y, z \in \mathcal{C}$.
satisfying three coherence conditions encoded by the pasting equalities:

\[
\begin{align*}
C(y,z) \times C(x,y) \times C(w,x) & \xrightarrow{G \times G \times G} D(Gy,Gz) \times D(Gx,Gy) \times D(Gw,Gx) \\
\alpha^{x,y,z} \times \text{id} \simeq & \\
C(x,z) \times C(w,x) & \xrightarrow{G \times G} D(Gx,Gz) \times D(Gw,Gx) \\
\alpha^{w,x,z} \simeq & \\
C(w,z) & \xrightarrow{G} D(Gw,Gz)
\end{align*}
\]

\[
\begin{align*}
C(y,z) \times C(x,y) \times C(w,x) & \xrightarrow{G \times G \times G} D(Gy,Gz) \times D(Gx,Gy) \times D(Gw,Gx) \\
\text{id} \times \alpha^{w,y,x} \simeq & \\
C(y,z) \times C(w,y) & \xrightarrow{G \times G} D(Gy,Gz) \times D(Gw,Gy) \\
\alpha^{w,y,z} \simeq & \\
C(w,z) & \xrightarrow{G} D(Gw,Gz)
\end{align*}
\]

\[
\begin{align*}
C(x,y) & \xrightarrow{G} D(Gx,Gy) \\
\text{id} \times \text{id} & \\
C(x,y) \times C(x,x) & \xrightarrow{G \times G} D(Gx,Gy) \times D(Gx,Gx) = C(y,y) \times C(x,y) \xrightarrow{G \times G} D(Gy,Gy) \times D(Gx,Gy) \\
\alpha^{x,y,y} \simeq & \\
C(x,y) & \xrightarrow{G} D(Gx,Gy)
\end{align*}
\]

where both of these latter composites equal the unit 2-cell \(\text{id}_{G_{x,y}}\).

A 2-functor is a pseudofunctor in which the unit and composition cells \(\iota\) and \(\alpha\) are identities. The notion of a 2-natural transformation (see Definition B.2.2) between 2-functors similarly generalizes to a pseudonatural transformation between pseudofunctors.

10.4.2. Definition. For any 2-categories \(\mathcal{C}\) and \(\mathcal{D}\) and pseudofunctors \(F, G : \mathcal{C} \to \mathcal{D}\), a pseudonatural transformation \(\phi : F \approx G\) is given by:

- a 1-cell \(\phi_x : Fx \to Gx \in \mathcal{D}\) for every object \(x \in \mathcal{C}\) and
- an invertible 2-cell in \(\mathcal{D}\)

\[
\begin{array}{ccc}
Fx & \xrightarrow{Ff} & Fy \\
\phi_x & \xrightarrow{\phi_f \simeq} & \phi_y \\
Gx & \xrightarrow{Gf} & Gy
\end{array}
\]

for each 1-cell \(f : x \to y \in \mathcal{C}\) so that this data
is natural, in the sense that for each 2-cell \( \alpha \) in \( C \) the pasted composites are equal.

\[
\begin{align*}
Fx & \xrightarrow{Ff} Fy & \quad & \quad
Gx & \xrightarrow{Gg} Gy
\end{align*}
\]

and

respects the composition and unit constraints specified by the pseudofunctors.

As suggested above, one instance in which pseudofunctors naturally arise is as inverses to 2-functors that define biequivalences. The pseudofunctors that arise in this manner are themselves biequivalences: surjective on objects up to equivalence and defining local equivalences on hom-categories. These functors are inverses in the sense that there exist pseudonatural equivalences between the composites and the identities, these being pseudonatural transformations that are componentwise equivalences; see Exercise 10.4.ii for an alternate characterization. Collectively, this data defines an equivalence of 2-categories in a sense appropriate to bicategory theory:

10.4.3. Proposition. If \( F: C \to D \) is a 2-functor between 2-categories \( C \) and \( D \) and a biequivalence then there exists a pseudofunctor \( G: D \xrightarrow{\sim} C \) that is also a biequivalence and is a pseudoinverse to \( F \) in the sense that there exist pseudonatural equivalences \( id_C \approx GF \) and \( FG \approx id_D \).

Proof. Exercise 10.4.v.

Proposition 10.4.3 describes a classical result in bicategory theory, so we feel content to leave its proof to the exercises; a proof in a slightly more general context also appears in [57, 7.4.1], where this
result is called “the bicategorical Whitehead theorem.” We shall also shortly prove a generalization subsuming this classical statement.

Recall from Definition 1.2.1 that an $\infty$-cosmos is, among other things, a category enriched in the cartesian closed category of quasi-categories, in the sense explicated in §A.1–A.2, while a cosmological functor is, among other things, an enriched functor between quasi-categorically enriched categories. To define a quasi-categorically enriched pseudofunctor, we need to extend the 1-category of quasi-categories and functors to a 2-category, so that we may use its 2-cells to encode the unit and composition coherences. Fortunately, we have such a 2-category at our disposal: the homotopy 2-category of quasi-categories $\mathbb{Q}Cat$. By Proposition 1.4.5, this 2-category of quasi-categories, functors between them, and natural transformations between these is cartesian closed, so we have well-behaved cartesian product and transposition operations on these 2-cells.

The extra dimension in the 2-category $\mathbb{Q}Cat$ enables us to define quasi-categorically enriched pseudofunctors as follows:

10.4.4. Definition. For quasi-categorically enriched categories $\mathcal{K}$ and $\mathcal{L}$, a quasi-categorically enriched pseudofunctor — a quasi-pseudofunctor for short — $G: \mathcal{K} \Rightarrow \mathcal{L}$ is given by:

- a mapping on objects $\mathcal{K} \ni x \mapsto Gx \in \mathcal{L}$;
- a functor of hom quasi-categories $G_{x,y}: \mathcal{K}(x,y) \to \mathcal{L}(Gx,Gy)$ for each $x, y \in \mathcal{K}$;
- an invertible 2-cell

$$
\begin{array}{ccc}
\mathcal{K}(x,x) & \xrightarrow{id_x} & \mathcal{L}(Gx,Gx) \\
\mathcal{K}(x,x) & \xleftarrow{\alpha_x} & \mathcal{L}(Gx,Gx)
\end{array}
$$

in the homotopy 2-category of quasi-categories for each $x \in \mathcal{K}$;

- an invertible 2-cell

$$
\begin{array}{ccc}
\mathcal{K}(y,z) \times \mathcal{K}(x,y) & \xrightarrow{G \times G} & \mathcal{L}(Gy,Gz) \times \mathcal{L}(Gx,Gy) \\
\mathcal{K}(x,z) & \xrightarrow{\alpha_{x,y,z}} & \mathcal{L}(Gx,Gz)
\end{array}
$$

in the homotopy 2-category of quasi-categories for each triple of objects $x, y, z \in \mathcal{K}$.
satisfying three coherence conditions encoded by the pasting equalities:

\[
\begin{array}{ccc}
\mathcal{K}(y, z) \times \mathcal{K}(x, y) \times \mathcal{K}(w, x) & \xrightarrow{G \times G \times G} & \mathcal{L}(Gy, Gz) \times \mathcal{L}(Gx, Gy) \times \mathcal{L}(Gw, Gx) \\
\downarrow & & \downarrow \\
\mathcal{K}(x, z) \times \mathcal{K}(w, x) & \xrightarrow{G \times G} & \mathcal{L}(Gx, Gz) \times \mathcal{L}(Gw, Gx) \\
\downarrow & & \downarrow \\
\mathcal{K}(w, z) & \xrightarrow{G} & \mathcal{L}(Gw, Gz)
\end{array}
\]

\[\equiv (10.4.5)\]

\[
\begin{array}{ccc}
\mathcal{K}(y, z) \times \mathcal{K}(x, y) \times \mathcal{K}(w, x) & \xrightarrow{G \times G \times G} & \mathcal{L}(Gy, Gz) \times \mathcal{L}(Gx, Gy) \times \mathcal{L}(Gw, Gx) \\
\downarrow & & \downarrow \\
\mathcal{K}(y, z) \times \mathcal{K}(w, y) & \xrightarrow{G \times G} & \mathcal{L}(Gy, Gz) \times \mathcal{L}(Gw, Gy) \\
\downarrow & & \downarrow \\
\mathcal{K}(w, z) & \xrightarrow{G} & \mathcal{L}(Gw, Gz)
\end{array}
\]

where both of these latter composites equal the unit 2-cell \(\text{id}_{Gx,y}\).

10.4.6. REMARK. To emphasize the analogy between Definitions 10.4.1 and 10.4.4, we write \(\mathbb{1}\) for the terminal quasi-category, which is also the nerve of the terminal category; elsewhere we write \(1\) for the terminal \(\infty\)-category in a generic \(\infty\)-cosmos. For any pair of objects \(a, b \in \mathcal{L}\) in a quasi-categorically enriched category,\n
\[\text{Fun}(\mathbb{1}, \mathcal{L}(a, b)) \cong \mathcal{L}(a, b),\]

and so \(\text{hFun}(\mathbb{1}, \mathcal{L}(a, b)) \cong h\mathcal{L}(a, b)\). Thus 2-cells in the homotopy 2-category of quasi-categories \(hQC\text{at}\) with domain \(\mathbb{1}\) and codomain \(\mathcal{L}(a, b)\) correspond to 2-cells in the homotopy 2-category of \(\mathcal{L}\) — defined exactly as in Definition 1.4.1 — from \(a\) to \(b\).

In particular, the data of the invertible 2-cell \(\tau_x\) is no more and no less than an invertible 2-cell

\[
\begin{array}{c}
Gx \xrightarrow{\text{id}_{Gx}} Gx \\
\downarrow \tau_x \equiv \downarrow \\
G \text{id}_x
\end{array}
\]

in the homotopy 2-category of \(\mathcal{L}\).

The notion of “quasi-pseudofunctor” introduced in Definition ?? should be regarded as a 2-categorical truncation of an \((\infty, 2)\)-categorical notion in the following sense:
10.4.7. Digression (quasi-pseudofunctors as \((\infty, 2)\)-functors). A quasi-categorically enriched functor between quasi-categorically enriched categories can be understood as a “functor of \((\infty, 2)\)-categories.” Indeed, the category of simplicially enriched categories supports a model structure that presents the \((\infty, 1)\)-category of \((\infty, 2)\)-categories, in which the fibrant objects are exactly the quasi-categorically enriched categories \([75, 0.0.4]\). However, as in the Bergner model structure of Digression 6.2.13, not all fibrant objects are cofibrant; here, as was the case there, the cofibrant objects are the simplicial computads. So it is not possible to model every functor of \((\infty, 2)\)-categories from a quasi-categorically enriched category \(\mathcal{K}\) to a quasi-categorically enriched category \(\mathcal{L}\) as a quasi-categorically enriched functor \(\mathcal{K} \to \mathcal{L}\). To model \((\infty, 2)\)-categorical functors strictly, one must first replace \(\mathcal{K}\) by a weakly equivalent simplicial computad.

In particular, this explains why the inverse to a cosmologically biequivalence is not necessarily a strict simplicial functor but something weaker. The 2-cell coherences that enumerate the data of a quasi-categorically enriched pseudofunctor can be understood as a truncation of the higher coherences of a functor of \((\infty, 2)\)-categories, much like the homotopy 2-category of quasi-categories is a truncation of the quasi-categorically enriched category of quasi-categories. Since a theme of this text is that much of \(\infty\)-category theory can be developed in the truncated homotopy 2-category rather than the full \((\infty, 2)\)-category, we decline to enumerate the higher coherences of an inverse to a cosmological biequivalence as part of Definition 10.4.4.

10.4.8. Definition. A quasi-pseudofunctor \(G : \mathcal{K} \rightrightarrows \mathcal{L}\) whose codomain \(\mathcal{L}\) is an \(\infty\)-cosmos is a biequivalence when it is:

(i) surjective on objects up to equivalence: if for all \(a \in \mathcal{L}\) there exists \(x \in \mathcal{K}\) so that \(Fx \simeq a\); and

(ii) a local equivalence of quasi-categories: if for every pair \(x, y \in \mathcal{K}\), the map

\[
\mathcal{K}(x, y) \xrightarrow{G_{x,y}} \mathcal{L}(Gx, Gy)
\]

is an equivalence of quasi-categories.

10.4.9. Remark. We find it convenient to assume that \(\mathcal{L}\) is an \(\infty\)-cosmos in Definition 10.4.8 because that provides us access to the equivalent characterizations of the equivalences in \(\mathcal{L}\) given by Theorem 1.4.7. In what follows we will ask that an equivalence \(a \simeq b\) in \(\mathcal{L}\):

- defines an equivalence in the homotopy 2-category of \(\mathcal{L}\) and

- induces an equivalence of quasi-categories \(\mathcal{L}(x, a) \simeq \mathcal{L}(x, b)\) in the homotopy 2-category \(hQC\) that is 2-natural in \(x\).

The latter of these properties implies the former, so if we required a notion of quasi-pseudofunctorial biequivalence between general quasi-categorically enriched categories, we could use this notion of equivalence in Definition 10.4.8. But we will make no use of the concept outside of the context provided by \(\infty\)-cosmoi and so prefer the simpler terminology. Note that we permit the domain \(\mathcal{K}\) to be merely quasi-categorically enriched.

Similarly:

10.4.10. Definition. For quasi-categorically enriched categories \(\mathcal{K}\) and \(\mathcal{L}\) and quasi-pseudofunctors \(F, G : \mathcal{K} \rightrightarrows \mathcal{L}\), a quasi-categorically enriched pseudonatural transformation — a quasi-pseudonatural transformation for short — \(\phi : F \Rightarrow G\) is given by:

- a 0-arrow \(\phi_x : Fx \Rightarrow Gx \in \mathcal{L}\) for every object \(x \in \mathcal{K}\) and
an invertible 2-cell

\[
\begin{array}{c}
\mathcal{K}(x, y) \\ F_{x,y} \\
\downarrow_{G_{x,y}} \\
\mathcal{L}(G_x, G_y) \\ \phi_{x,y} \\
\downarrow_{\phi_{x,y}^\circ} \\
\mathcal{L}(F_x, G_y) \\
\end{array}
\]

in the homotopy 2-category of quasi-categories, for each pair of objects \(x, y \in \mathcal{K}\) so that this data respects the composition and unit constraints specified by the quasi-pseudofunctors, as expressed by the following two pasting diagrams

\[
\begin{array}{c}
\mathcal{K}(y, z) \times \mathcal{K}(x, y) \\ F \times F \\
\downarrow_{\alpha_{x,y,z}} \\
\mathcal{K}(x, z) \\ F \\
\downarrow_{G} \\
\mathcal{L}(G_x, G_z) \\
\phi_{x,z} \\
\downarrow_{\phi_{x,z}^\circ} \\
\mathcal{L}(F_x, G_z) \\
\end{array}
\]

10.4.11. Remark. There is an analogy between Definitions 10.4.2 and 10.4.10 that parallels the analogy between Definitions 10.4.1 and 10.4.4 that is concealed by our presentation. The naturality requirement for the invertible 2-cell components of a pseudonatural transformation \(\phi : F \approx G\) between pseudofunctors \(F, G : C \to D\) tells us that they assemble into a natural isomorphism between the
functors

$$C(x, y) \xrightarrow{F_{xy}} D(Fx, Fy)$$
$$G_{xy} \downarrow \phi_{xy} = \phi_{xy} \downarrow \phi = G_{xy}$$

$$D(Gx, Gy) \xrightarrow{-\phi_{x}} D(Fx, Gy)$$

for every $x, y \in C$. The coherence conditions that express the compatibility of these natural isomorphisms with the composition and unit constraints can then be expressed in the form appearing in Definition 10.4.10, but since two natural isomorphisms are equal just when their components are equal, we can reduce these coherence conditions to the two remaining pasting identities of Definition 10.4.2 expressed in terms of the components of $\phi$.

The data of a natural isomorphism between functors between quasi-categories is more intricate than the data of a natural isomorphism between functors between categories, which is why the coherence conditions in Definition 10.4.10 must be expressed in a more universal way. However, the coherence conditions of Definition 10.4.2 can be extracted from these as follows.

Recall the 0-arrows in $\mathcal{K}(x, y)$ correspond to functors $f: \mathbf{1} \to \mathcal{K}(x, y)$. By Remark 10.4.6, the restriction $\phi_{xy} f$ defines the component

\[
\begin{array}{ccc}
Fx & \xrightarrow{Ff} & Fy \\
\phi_x & \downarrow \phi_{xy} & \phi_y \\
Gx & \xrightarrow{Gf} & Gy
\end{array}
\]

of an invertible 2-cell in the homotopy 2-category of $\mathcal{L}$. This 2-cell is automatically “natural,” in the sense that for each 2-cell $x \xRightarrow{g} y$ in the homotopy 2-category of $\mathcal{K}$ the pasted composites are equal

\[
\begin{array}{ccc}
Fx & \xRightarrow{Ff} & Fy \\
\phi_x & \downarrow \phi_{xy} & \phi_y \\
Gx & \xRightarrow{Gf} & Gy
\end{array} = \begin{array}{ccc}
Fx & \xRightarrow{Ff} & Fy \\
\phi_x & \downarrow \phi_{xy} & \phi_y \\
Gx & \xRightarrow{Gf} & Gy
\end{array}
\]

in the homotopy 2-category of $\mathcal{L}$. This follows by “naturality of whiskering,” since both pasted composites are represented by the horizontal composite

\[
\begin{array}{ccc}
\mathbf{1} & \xRightarrow{f} & \mathcal{K}(x, y) \\
\mathbf{1} & \xRightarrow{g} & \mathcal{K}(x, y)
\end{array} \xRightarrow{(\phi_{xy} \circ F_{xy})} \mathcal{L}(Fx, Gy)
\]

in the homotopy 2-category of quasi-categories.

Similarly, the composition and unit diagrams of Definition 10.4.10 imply that the corresponding diagrams displayed in Definition 10.4.2 commute in the homotopy 2-category of $\mathcal{L}$; see Exercise 10.4.iii.
For any quasi-categorically enriched category \( \mathcal{K} \), the hom bifunctor \( \mathcal{K}(-, -) \colon \mathcal{K}^{\text{op}} \times \mathcal{K} \to \mathcal{QC} \) is a quasi-categorically enriched functor.

**10.4.12. Lemma.** The action on homs of a quasi-pseudofunctor \( F \colon \mathcal{K} \Rightarrow \mathcal{L} \) between quasi-categorically enriched categories defines a quasi-pseudonatural transformation

\[
F_{-,-} \colon \mathcal{K}(-, -) \Rightarrow \mathcal{L}(F-, F-)
\]

between quasi-pseudonatural functors \( \mathcal{K}^{\text{op}} \times \mathcal{K} \Rightarrow \mathcal{QC} \).

**Proof.** The 2-cell component of the quasi-pseudonatural transformation associated to a pair of objects \((x, y)\) and \((w, z)\) in \( \mathcal{K}^{\text{op}} \times \mathcal{K} \) is given by

\[
\mathcal{K}(y, z) \times \mathcal{K}(w, x) \xrightarrow{\circ} \mathcal{K}(w, z)^{\mathcal{K}(x, y)} \xrightarrow{\sim} \mathcal{L}(Fw, Fz)^{\mathcal{L}(Fx, Fy)} \xrightarrow{\sim} \mathcal{L}(Fw, Fz)^{\mathcal{K}(x, y)}
\]

where \( \alpha_{w, y, z, x} \) is a transpose of the common 2-cell defined by (10.4.5). We leave the verification of the composition and unit axioms to Exercise 10.4.iv.

**10.4.13. Definition.** A quasi-pseudonatural transformation \( \phi \colon F \Rightarrow G \) between quasi-pseudofunctors \( F, G \colon \mathcal{K} \Rightarrow \mathcal{L} \) whose codomain is an \( \infty \)-cosmos is a quasi-pseudonatural equivalence if each of its components \( \phi_x \colon Fx \Rightarrow Gx \) defines an equivalence in the homotopy 2-category of \( \mathcal{L} \).

For the reasons noted in Remark 10.4.9, it is convenient to assume that \( \mathcal{L} \) is an \( \infty \)-cosmos so we need not be more explicit about the appropriate notion of equivalence in the target category. Our interest in the class of quasi-pseudonatural equivalences stems from the following result, which can be understood as a version of the bicategorical Yoneda lemma in the context of quasi-categorically enriched categories, quasi-pseudofunctors, quasi-pseudonatural transformations, and the “modifications” between them.

**10.4.14. Lemma.** If there exists a quasi-pseudonatural equivalence

\[
\phi \colon \mathcal{K}(-, a) \Rightarrow \mathcal{K}(-, b)
\]

between the simplicial functors \( \mathcal{K}^{\text{op}} \Rightarrow \mathcal{QC} \) represented by a pair of objects \( a, b \) in an \( \infty \)-cosmos \( \mathcal{K} \), then \( a \) and \( b \) are equivalent in \( \mathcal{K} \).

**Proof.** We will show that the 0-arrow \( y := \phi_a(\text{id}_a) \colon a \to b \) is an equivalence in \( \mathcal{K} \). First observe from the diagram

\[
\begin{array}{ccc}
\mathcal{K}(x, a) & \xrightarrow{\circ} & \mathcal{K}(x, a)^{\mathcal{K}(a, a)} \\
\downarrow \phi_x & & \downarrow \phi_x \circ - \\
\mathcal{K}(x, b)^{\mathcal{K}(a, b)} & \xrightarrow{- \circ \phi_a} & \mathcal{K}(x, b)^{\mathcal{K}(a, a)} \\
\downarrow \phi_y & & \downarrow \phi_x \\
\mathcal{K}(x, b) & \xrightarrow{ev_x} & \mathcal{K}(x, b)
\end{array}
\]

that for every \( x \in \mathcal{K} \) the component \( \phi_x \colon \mathcal{K}(x, a) \Rightarrow \mathcal{K}(x, b) \) — the top-right composite in the above diagram — is isomorphic in the homotopy 2-category of quasi-categories to postcomposition with \( y \) — the lower-left composite in the above diagram. In particular, by Exercise 1.4.iv the map
\( y \circ - : \mathcal{K}(x, a) \cong \mathcal{K}(x, b) \) is an equivalence for any \( x \in \mathcal{K} \), and thus so is \( y \circ - : \mathcal{K}(x, a) \cong \mathcal{K}(x, b)\). Via the equivalence \( y \circ - : \mathcal{K}(b, a) \cong \mathcal{K}(b, b) \), we may choose a 0-arrow \( z : b \to a \) so that \( \beta : yz \cong \text{id}_b \) in the homotopy 2-category \( \mathcal{K} \). Now \( \text{id}_a \) and \( zy \) define a pair of 0-arrows in \( \mathcal{K}(a, a) \) whose images under the equivalences \( y \circ - : \mathcal{K}(a, a) \cong \mathcal{K}(a, b) \) are isomorphic via \( \beta y : zy \cong y \). Hence, there exists an isomorphism \( \alpha : \text{id}_a \cong zy \) in the homotopy 2-category \( \mathcal{K} \), completing the proof that \( a \cong b \) in \( \mathcal{K} \).

Quasi-pseudonatural equivalences may be constructed as adjoint equivalence inverses of simplicial natural transformations that define componentwise equivalences.

10.4.15. Lemma. Consider a simplicial natural transformation \( \xymatrix{ \mathcal{K} \ar[r]^-F & \mathcal{L} } \) between quasi-categorically enriched functors between \( \infty \)-cosmoi whose 0-arrow components \( \phi_x : Fx \Rightarrow Gx \) all define equivalences in \( \mathcal{L} \). Then any choice of adjoint equivalence inverses \( \psi_x : Gx \Rightarrow Fx \) assemble into the components of a quasi-pseudonatural transformation \( \psi : G \Rightarrow F \) that is a quasi-pseudonatural equivalence.

Proof. The components of the quasi-pseudonatural transformation \( \psi \) are defined by the adjoint equivalence inverse arrows \( \psi_x : Gx \Rightarrow Fx \) and by the pasted composite natural transformation

\[
\begin{array}{c}
\xymatrix{ \mathcal{K}(x, y) & \mathcal{L}(Gx, Gy) \\
Fxy & \xymatrix{ \mathcal{L}(Fx, Fy) & \mathcal{L}(Fx, Gy) & \mathcal{L}(Gx, Gy) \\
\ar[r]^-{\phi_y} & \ar[l]_{\eta_y} & \ar[r]^-{\psi_y} & \ar[l]_{\epsilon_y} } \\
\ar[d]_-{Fxy} & \xymatrix{ \mathcal{L}(Fx, Fy) \ar[d]_-{\psi_y} & L(Gx, Fy) \\
\ar[r]^-{\phi_y} & \ar[l]_{\eta_y} \xymatrix{ \ar[r]^-{\psi_y} & \ar[l]_{\epsilon_y} } } \\
\end{array}
\]

involving the unit and counit isomorphisms of the adjoint equivalence.

Since \( F \) and \( G \) are simplicial functors, the unit condition simplifies to ask only that the component of this pasted natural transformation at the identity arrow \( \text{id}_x : 1 \to \mathcal{K}(x, x) \) is an identity 2-cell \( \text{id}_{\psi_x} \). This component is the pasted composite

\[
\begin{array}{c}
\xymatrix{ Gx & Gx \\
\ar[r]_-{\psi_x} & \ar[l]^-{\phi_x} \xymatrix{ \ar[r]_-{\psi_x} & \ar[l]^-{\epsilon_x} } } \\
\end{array}
\]

which is indeed the identity, since the specified data defines an adjoint equivalence.
Similarly, to verify the composition axiom, we must show that the composite
\[
\mathcal{K}(y, z) \times \mathcal{K}(x, y) \xrightarrow{G_{x,z}} \mathcal{L}(G_x, G_z) \xrightarrow{\phi_{x,z}} \mathcal{L}(F_x, G_z) \xrightarrow{\eta_x \equiv} \mathcal{L}(F_x, F_z) \xrightarrow{\psi_x^\circ} \mathcal{L}(G_x, G_z)
\]
equals
\[
\mathcal{K}(y, z) \times \mathcal{K}(x, y) \xrightarrow{G \times G} \mathcal{L}(G_y, G_z) \times \mathcal{L}(G_x, G_y) \xrightarrow{\eta_y \equiv} \mathcal{L}(F_y, F_z) \times \mathcal{L}(G_x, G_y) \xrightarrow{\psi_y^\circ} \mathcal{L}(G_x, F_z) \xrightarrow{\psi_x^\circ} \mathcal{L}(G_x, G_z)
\]
The pre- and post-composition maps appearing in this diagram are 2-natural, so for instance the whiskered composite of \(\varepsilon_y\) and \(\circ \psi_x\) can be formed in either order. Using this commutativity property repeatedly in the second pasting diagram and applying the triangle identity \(\phi_y \varepsilon_y \cdot \eta_y \phi_y = \text{id}_{\phi_y}\), the second pasting diagram reduces to the first one.

We now show that any biequivalence \(F : \mathcal{K} \Rightarrow \mathcal{L}\) of quasi-categorically enriched categories admits a quasi-pseudofunctorial “inverse” \(G : \mathcal{L} \Rightarrow \mathcal{K}\) equipped with quasi-pseudonatural equivalences \(\eta : \text{id}_\mathcal{K} \Rightarrow GF\) and \(\varepsilon : FG \Rightarrow \text{id}_\mathcal{L}\).

10.4.16. Proposition. If \(F : \mathcal{K} \rightarrow \mathcal{L}\) is a quasi-categorically enriched functor between \(\infty\)-cosmoi and a biequivalence then there exists a quasi-pseudofunctor \(G : \mathcal{L} \Rightarrow \mathcal{K}\) that is also a biequivalence. Moreover \(G\) is a quasi-pseudoinverse to \(F\) in the sense that there exist quasi-pseudonatural equivalences \(\text{id}_\mathcal{K} \Rightarrow GF\) and \(FG \Rightarrow \text{id}_\mathcal{L}\).

Proof. To coherently define an inverse to a biequivalence \(F : \mathcal{K} \Rightarrow \mathcal{L}\), we “fully specify” its data, choosing:

- (\(\beta\)) fully specified adjoint equivalences \(\varepsilon_a : Fx_a \Rightarrow a\) for each \(a \in \mathcal{L}\) and
- (\(\gamma\)) fully specified inverse adjoint equivalences of quasi-categories

\[
\mathcal{K}(x, y) \xrightarrow{F_{x,y}} \mathcal{L}(Fx, Fy)
\]
for each pair \(x, y \in \mathcal{K}\) whose inverse is quasi-pseudonatural in \(x\) and \(y\).
In \((\gamma)\), we apply to the simplicial natural transformation \(F_{-,-} : \mathcal{K}(-,-) \to \mathcal{L}(F-,F-)\) to observe that the pointwise adjoint equivalences to these maps assemble into a quasi-pseudonatural transformation, which is also a pointwise equivalence.

Now, to define \(G: \mathcal{L} \to \mathcal{K}\), use \((\beta)\) to specify for each \(a \in \mathcal{L}\) an object \(Ga \equiv x_a \in \mathcal{K}\) together with an equivalence \(e_a : FGa \simeq a\) in \(\mathcal{L}\). This defines the mapping of \(G\) on objects and the 0-arrow components of the quasi-pseudonatural transformation \(e\). To define the action of \(G\) on hom quasi-categories, use this data and \((\gamma)\) to define

\[
G_{a,b} := \mathcal{L}(a,b) \xrightarrow{(-e_a e_b^{-1})} \mathcal{L}(FGa,FGb) \xrightarrow{F_{Ga,Gb}^{-1}} \mathcal{K}(Ga,Gb)
\]

For each \(a \in \mathcal{L}\) define \(\iota_a : id_{Ga} \cong G_{a,a} id_a\) to be the composite

\[
\begin{array}{ccc}
\mathcal{L}(a,a) & \xrightarrow{(-e_a e_a^{-1})} & \mathcal{L}(FGa,FGa) \\
\mathcal{L}(b,b) \times \mathcal{L}(a,b) & \xrightarrow{(-e_b e_b^{-1}) \times (-e_a e_a^{-1})} & \mathcal{L}(FGb,FGc) \times \mathcal{L}(FGa,FGb) \\
\mathcal{L}(a,c) & \xrightarrow{(-e_a e_c^{-1})} & \mathcal{L}(FGa,FGc) \\
\mathcal{K}(Ga,Ga) & \xrightarrow{\gamma} & \mathcal{K}(Ga,Gc) \\
\end{array}
\]

of the isomorphism \(\beta_a : e_a^{-1} \circ e_a \cong id_{Ga}\) in the homotopy 2-category of \(\mathcal{L}\) with the component of the isomorphism \(\gamma : F_{Ga,Ga}^{-1} \circ F_{Ga,Ga} \cong id_{Ga,Ga}\) at \(id_Ga\). For each \(a, b, c \in \mathcal{L}\), define \(\alpha_{a,b,c}\) to be the composite

\[
\begin{array}{ccc}
\mathcal{L}(b,c) \times \mathcal{L}(a,b) & \xrightarrow{(-e_b e_c^{-1}) \times (-e_a e_b^{-1})} & \mathcal{L}(FGb,FGc) \times \mathcal{L}(FGa,FGb) \\
\mathcal{L}(a,c) & \xrightarrow{(-e_a e_c^{-1})} & \mathcal{L}(FGa,FGc) \\
\mathcal{K}(Ga,Ga) & \xrightarrow{\gamma} & \mathcal{K}(Ga,Gc) \\
\end{array}
\]

of the canonical natural transformations built from the data of \((\beta)\) and \((\gamma)\).

We next verify that these choices make \(G\) into a quasi-pseudofunctor. For the unit condition, we must verify that the composite

\[
\begin{array}{ccc}
\mathcal{L}(a,b) & \xrightarrow{(-e_a e_b^{-1})} & \mathcal{L}(FGa,FGb) \\
\mathcal{L}(b,b) \times \mathcal{L}(a,b) & \xrightarrow{(-e_b e_b^{-1}) \times (-e_a e_a^{-1})} & \mathcal{L}(FGb,FGb) \times \mathcal{L}(FGa,FGb) \\
\mathcal{L}(a,b) & \xrightarrow{(-e_a e_b^{-1})} & \mathcal{L}(FGa,FGb) \\
\mathcal{K}(Ga,Ga) & \xrightarrow{\gamma} & \mathcal{K}(Ga,Gb) \\
\end{array}
\]

is the identity; in fact, each pair of vertical composites is the identity. On the left-hand side, this is on account of one of the triangle equality relations for the adjoint equivalence \(e_b\). On the right-hand side, this is a consequence of quasi-pseudonaturality of the pair \(F_{Ga,Gb}^{-1}\) and \(\gamma\) established in Lemma 10.4.15. The right unit constraint and associativity conditions are similar. This completes the proof that \(G: \mathcal{L} \to \mathcal{K}\) defines a quasi-pseudofunctor.

By construction, the quasi-pseudofunctor \(G\) is a local equivalence: its action on homs is defined by composing an equivalence with a map induced by pre- and post-composing with equivalences in the
∞-cosmos \( \mathcal{L} \), which is then an equivalence by Corollary 1.4.9. We use this local equivalence to argue that for each \( x \in \mathcal{K} \), there is an equivalence \( \eta_x : x \Rightarrow GFx \), proving essential surjectivity of \( G \). This component is defined by applying the specified inverse adjoint equivalence \( F^{-1}_{x,GFx} : \mathcal{L}(Fx,FGFx) \Rightarrow \mathcal{K}(x,GFx) \) of \( (\gamma) \) to the inverse of the specified adjoint equivalence \( \varepsilon^{-1}_{Fx} : Fx \Rightarrow FGFx \) of \( (\beta) \). Since \( F \) is a cosmological biequivalence, which carries the map \( \eta_x \) to an equivalence in \( \mathcal{L} \), \( \eta_x \) is itself an equivalence in \( \mathcal{K} \). Thus, the quasi-pseudofunctor \( G \) is an biequivalence.

It remains only to check quasi-pseudonaturality of \( \eta \) and \( \varepsilon \). For the latter, we define the component

natural isomorphism by the pasting diagram

For the former, using the definition \( \eta_x := F^{-1}e^{-1}_{Fx} \) and the quasi-pseudonaturality of \( F^{-1}_{-,-} \), we have a pasting diagram

which defines component natural isomorphism. We leave the verification that these natural transformations satisfy the unit and composition coherence conditions to define quasi-pseudonatural equivalences \( \eta : \text{id}_{\mathcal{K}} \Rightarrow GF \) and \( \varepsilon : FG \Rightarrow \text{id}_{\mathcal{L}} \) to the reader. \( \square \)

It is easily verified that composites of quasi-pseudofunctors are quasi-pseudofunctors and composites of biequivalences are biequivalences. Hence:

10.4.17. Corollary. Any zig-zag of cosmological biequivalences composes to define a quasi-pseudofunctor \( \mathcal{K} \Rightarrow \mathcal{L} \) between ∞-cosmoi that is also a biequivalence. \( \square \)

Moreover, the preservation and reflection properties of cosmological biequivalences established in Proposition 10.3.6 extend to their quasi-pseudofunctorial inverses, as the reader is invited to explore in Exercise 10.4.vi.

Exercises.

10.4.i. Exercise. For a fixed pair of 2-categories \( \mathcal{C} \) and \( \mathcal{D} \), show that the collection of pseudofunctors \( \mathcal{C} \Rightarrow \mathcal{D} \), pseudonatural transformations, and modifications (see Definition B.2.3) assemble into a 2-category.

10.4.ii. Exercise ([57, 6.2.16]). For a pseudonatural transformation \( \phi : F \Rightarrow G \) between pseudofunctors \( F, G : \mathcal{C} \Rightarrow \mathcal{D} \) between 2-categories \( \mathcal{C} \) and \( \mathcal{D} \), show that the following are equivalent.

- Each 1-cell component \( \phi_x : Fx \Rightarrow Gx \) is an equivalence in \( \mathcal{D} \).
- The 1-cell \( \phi \) defines an equivalence in the 2-category described in Exercise 10.4.i.
10.4.iii. **Exercise.** Let $\phi : F \Rightarrow G$ be a quasi-pseudonatural transformation between quasi-pseudofunctors $F, G : \mathcal{K} \to \mathcal{L}$. Show that for any pair of 0-arrows $f : x \to y$ and $k : y \to z$ in the $\mathcal{K}$, the diagrams

\[
\begin{align*}
F_{yz} & \xrightarrow{\phi_{yz}} F_k \\
G_{x} & \xrightarrow{G(kf)} G_z
\end{align*}
\]

and

\[
\begin{align*}
F_{xf} & \xrightarrow{\alpha_{f,g}} F_{kf} \\
G_{x} & \xrightarrow{G(kf)} G_z
\end{align*}
\]

commute in the homotopy 2-category of $\mathcal{L}$.

10.4.iv. **Exercise.** Finish the proof of Lemma 10.4.12.

10.4.v. **Exercise.** Derive a proof of Proposition 10.4.3 from Proposition 10.4.16.

10.4.vi. **Exercise.** Develop a heuristic argument that explains why any $\infty$-categorical property or structure that is preserved and reflected by a cosmological biequivalence is also preserved and reflected by its inverse quasi-pseudofunctor.
CHAPTER 11

Model Independence

Our aim in this chapter is to prove that the theory of $\infty$-categories is invariant under change of model. Part of the meaning of this result is established in Chapter 10, where we prove that the $\infty$-categorical notions developed in this text are preserved, reflected, and created, by (zig-zags of) cosmological biequivalences, which provide our change of model functors. But our aim here is to establish something stronger: that statements about $\infty$-categories that may have been proven by “analytic” techniques particular to a single $\infty$-cosmos are also model-independent, provided that the statements are expressible in a suitable equivalence-invariant language. Chapter 12 illustrates applications of this transfer principle.

Some papers in the $\infty$-categorical literature suggest that experts should be able to translate the results they contain to other models. The aim of §11.1, which previews the line of reasoning that underpins our main theorem in this chapter but is subsumed by the later sections, is to give the reader confidence that they are now one of the experts. In §11.1, we observe that ad hoc translations of $\infty$-categorical data and properties between biequivalent $\infty$-cosmoi can be given relatively mechanically and in excruciating detail, if desired.

The problem with our naïve explorations of the model-independence of $\infty$-category theory is they are ad-hoc and tiresome. In §11.2, we pursue a more systematic result. We review the construction of the virtual equipment of modules associated to an $\infty$-cosmos and explain why it describes a suitable context for proving the model-independence of the fundamental $\infty$-categorical notions. We then prove in Theorem 11.2.6 that a cosmological biequivalence induces a biequivalence of virtual equipments, and revisit the results proven in an ad hoc fashion in §11.1 from the vantage point of this result.

Informally, Theorem 11.2.6 means that any $\infty$-categorical notion that can be encoded as a property of the virtual equipment of modules, is model-independent: a biequivalence of virtual equipments gives a mechanism by which results proven with one model of $\infty$-categories can be transferred to another model. But how can we be sure when a statement about $\infty$-categories that has been expressed in the language of virtual equipments is in fact invariant under a biequivalence of virtual equipments?

Building on past work of Blanc [18], Freyd [42], Preller [89], and Cartmell [26], Michael Makkai has been in pursuit of a higher categorical foundation of mathematics. In particular, his First-Order Logic with Dependent Sorts (FOLDS) [80] provides a formal language for writing mathematical sentences about finite-dimensional higher categorical structures. In §11.3, we sketch the key ideas behind Makkai’s FOLDS framework and explain how his work specializes to show that any statement written in the “language of 2-categories” is invariant under a biequivalence between 2-categories.

Since $\infty$-categories live as objects in an infinite-dimensional category, it is not immediately apparent that Makkai’s theory is applicable to the situation at hand. However, a key theme of this text is that a significant chunk of $\infty$-category theory can be developed in a truncated finite-dimensional framework: namely the virtual equipment of modules. In §11.4, we adapt Makkai’s framework to prove that any statement that can be expressed in the “language of virtual equipments,” as we define it in a very precise sense, gives rise to a model-independent statement about $\infty$-categories.
11.1. Ad Hoc Model-Invariance of $\infty$-Category Theory

The claim that “the theory of $\infty$-categories is model-independent” should certainly encompass assertions like:

- A functor between $\infty$-categories admits a left adjoint in a particular model if and only if it admits a left adjoint in every model.
- An $\infty$-category-valued diagram has a limit in one model if and only if it has a limit in every model.

In our setting, change-of-model functors such as (10.0.1) define cosmological biequivalences, or zig-zags thereof. Thus, along these lines, an ad hoc approach to proving the model-independence of the basic category theory of $\infty$-categories is provided by elaborations of Proposition 10.3.6, for instance as described in the following theorem:

11.1.1. THEOREM (ad hoc model independence). The following notions are preserved, reflected, and created by any cosmological biequivalence:

(i) A left or right adjoint to a functor $u: A \to B$.

(ii) A limit or a colimit for a $J$-indexed diagram $d: 1 \to A^J$ in an $\infty$-category $A$.

Proof. For (i), if $u: A \to B$ admits a left adjoint $f: B \to A$, then this adjunction is preserved by any 2-functor, and hence by any cosmological functor $F: \mathcal{K} \to \mathcal{L}$. If there merely exists $f: B \to A$ in $\mathcal{K}$ so that $Ff \dashv Fu$ in $\mathcal{L}$, then in the case where $F$ is a biequivalence, Corollary 10.3.2(iii) can be used to lift the unit and counit from $\mathcal{L}$ to define 2-cells $\eta: \text{id}_B \Rightarrow uf$ and $\epsilon: fu \Rightarrow \text{id}_A$ in $\mathcal{K}$. A priori the composites $\epsilon f \cdot f \eta$ and $\eta u \cdot \epsilon u$ need not be identities, but they will be invertible, which by Lemma 2.1.11 is enough to guarantee a genuine adjunction $f \dashv u$. A similar line of reasoning can be used in the absence of a candidate left adjoint using Corollary 10.3.2(ii) to lift the left adjoint from $\mathcal{L}$ to a functor $f: B \to A$ in $\mathcal{K}$ whose image is isomorphic to the left adjoint to $Fu$. The rest of the argument proceeds as before.

For (ii), given an absolute lifting diagram in $\mathcal{L}$ as displayed on the left

$$
\begin{array}{ccc}
1 & \xleftarrow{Fd} & FA^l \\
\lambda & \downarrow{\Delta} & \\
F \eta & \downarrow{\Delta} & A^l
\end{array}
$$

Corollary 10.3.2(ii) and (iii) yield a 1-cell $\ell: 1 \to A$ with $F \ell \cong \tilde{\ell}$ and a 2-cell $\lambda: \Delta \ell \Rightarrow d$, as displayed on the right, so that $F \lambda$ composes with the isomorphism $F \tilde{\ell} \cong \tilde{\ell}$ to $\tilde{\lambda}$. Our task is to show that that this data defines an absolute right lifting diagram in $\mathcal{K}$, which amounts to showing for all objects $X$ and for all maps $a: X \to A$ that the composition operation with $\lambda$ induces a bijection

$$
\begin{array}{ccc}
\text{hFun}(X, A)(a, \ell) & \xrightarrow{\text{hFun}(X, A^l)(\Delta a, d!)} & \text{hFun}(X, A^l)(\Delta a, d!)
\end{array}
$$

On account of the isomorphisms of Corollary 10.3.2(ii) and (iii), this follows from the corresponding encoding of the universal property of $\lambda$ in $\mathcal{L}$.

This argument also shows that absolute liftings are created; an easier argument along the same lines proves that the universal property of absolute lifting diagrams is reflected. To see that absolute lifting
diagrams are also preserved, Corollary 10.3.2(i) must be invoked to lift any cone in $\mathcal{L}$ with summit $Y$ over the 2-cell $F \lambda$ to an equivalent one in $\mathcal{K}$ with summit $X$ chosen so that $FX \simeq Y$. As the local bijections Corollary 10.3.2(ii) and (iii) can also be defined relative to specified equivalences of objects, the same style of argument goes through. □

The $\infty$-categorical notions considered in Theorem 11.1.1 are efficiently expressed as equivalence-invariant predicates concerning the homotopy 2-category of an $\infty$-cosmos. Since biequivalences of $\infty$-cosmoi induce biequivalences of homotopy 2-categories, they can easily be seen to preserve, reflect, and create statements of this form. But there are other $\infty$-categorical properties that are awkward to express in the homotopy 2-category — for instance, the assertion that a given isofibration defines a discrete cartesian fibration — which is encoded via an equivalence of modules. We now argue that the calculus of modules is invariant under “change of model functors” and argue that this result provides the sought for model-independence statement.

Exercises.

11.1i. Exercise. Pick your favorite $\infty$-categorical notion and give an ad hoc proof of its model independence.

11.2. A Biequivalence of Virtual Equipments

A more systematic approach to model-independence makes use of most comprehensive framework for the formal category theory of $\infty$-categories, namely the virtual equipment of modules. We briefly review its essential features. Recall from Chapter 8, that the virtual double category of modules $\mathbb{Mod}(\mathcal{K})$ in an $\infty$-cosmos $\mathcal{K}$ consists of

- a category of objects and vertical arrows, here the $\infty$-categories and $\infty$-functors, drawn vertically
- for any pair of objects $A, B$, a class of horizontal arrows $A \xleftrightarrow{E} B$, here the modules $(q, p) : E \to A \times B$ from $A$ to $B$
- cells, with boundary depicted as follows

\[
\begin{array}{c}
A_0 \xrightarrow{E_1} A_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} A_n \\
\downarrow f \quad \Downarrow f \quad \quad \downarrow g
\end{array} \quad \begin{array}{c}
B_0 \xrightarrow{E_1} A_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} A_n \\
\downarrow F \quad \Downarrow F \quad \quad \downarrow G
\end{array}
\]

including, in the case $A_0 = A_n$, those whose horizontal source has length zero. Here, a cell with the displayed boundary is an isomorphism class of objects in the functor space

\[
\begin{array}{c}
\text{Fun}_{f \times g}(E_1 \times \cdots \times E_{n+1}, \mathbb{F}) \\
\downarrow \\
\text{Fun}(E_1 \times \cdots \times E_{n+1}, \mathbb{F})
\end{array} \xrightarrow{a} 
\begin{array}{c}
\text{Fun}(E_1 \times \cdots \times E_{n+1}, B_0 \times B_n) \\
\downarrow \\
\text{Fun}(E_1 \times \cdots \times E_{n+1}, \mathbb{F})
\end{array}
\]

i.e., a fibered isomorphism class of maps of spans over $f \times g$.
• a composite cell, for any configuration

\[
\begin{array}{cccc}
A_0 & \rightarrow & A_1 & \rightarrow & \cdots & \rightarrow & A_n \\
f_0 & \downarrow & f_1 & \downarrow & \cdots & \downarrow & f_n \\
B_0 & \rightarrow & B_1 & \rightarrow & \cdots & \rightarrow & B_n \\
g & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \downarrow & h \\
C_0 & \rightarrow & C_n
\end{array}
\]

• an identity cell for every horizontal arrow

\[
\begin{array}{c}
A \overset{E}{\rightarrow} B \\
\| & \| & \| \\
A \overset{E}{\rightarrow} B
\end{array}
\]

so that composition of cells is strictly associative and unital in the usual multi-categorical sense.

11.2.1. Lemma. A cosmological functor \( F : \mathcal{K} \rightarrow \mathcal{L} \) induces a functor \( F : \text{Mod}(\mathcal{K}) \rightarrow \text{Mod}(\mathcal{L}) \) of virtual double categories, preserving all of the structure.

Proof. In Corollary 8.1.16, the categorical structures in the virtual double category of modules are inherited from the double category of two-sided isofibrations. We can understand the action of a cosmological functor on the virtual double category of modules by taking a similar route.

As outlined in Exercise 8.1.i, the non-unital double category of two-sided isofibrations can be understood as a quotient of the “non-unital internal category” of \( \infty \)-cosmoi and cosmological functors

\[
\begin{array}{c}
\mathcal{K}^{\otimes} \times \mathcal{K}^{\otimes} \xrightarrow{\circ} \mathcal{K}^{\otimes} \\
\xrightarrow{\text{\text{\text{\text{\text{l-cod}}}}}} \xrightarrow{\text{\text{\text{\text{\text{r-cod}}}}}} \mathcal{K}
\end{array}
\]

where \( \mathcal{K}^{\otimes} \) is the \( \infty \)-cosmos of two-sided isofibrations and \( \text{l-cod}, \text{r-cod} : \mathcal{K}^{\otimes} \rightarrow \mathcal{K} \) refer to the left and right codomain functors, that map a two-sided isofibration \( A \leftarrow E \rightarrow B \) to the base \( \infty \)-categories \( A \) and \( B \) of the span. The pullback

\[
\begin{array}{c}
\mathcal{K}^{\otimes} \times \mathcal{K}^{\otimes} \rightarrow \mathcal{K}^{\otimes} \\
\downarrow & \downarrow \\
\mathcal{K}^{\otimes} & \rightarrow \mathcal{K}
\end{array}
\]

which could be referred to as the \( \infty \)-cosmos of horizontal composable pairs of two-sided isofibrations \( A \leftarrow E \rightarrow B \leftarrow F \rightarrow C \), is an \( \infty \)-cosmos by Exercise 6.1.iii. The composition functor \( \circ : \mathcal{K}^{\otimes} \times \mathcal{K}^{\otimes} \rightarrow \mathcal{K}^{\otimes} \), which sends a horizontal composable pair of two-sided isofibrations to a chosen composite span, is associative only up to simplicial natural isomorphism, which accounts for the “pseudo-ness” in the horizontal composition in the double category of two-sided isofibrations. The (non-unital pseudo) double category of two-sided isofibrations can be understood as the quotient of this structure obtained by replacing the \( \infty \)-cosmos \( \mathcal{K} \) by its underlying category and replacing the \( \infty \)-cosmos \( \mathcal{K}^{\otimes} \) by the
quotient 1-category with the same objects but with hom-sets defined to be the isomorphism classes of vertices in the functor spaces.

Now any cosmological functor \( F: \mathcal{K} \to \mathcal{L} \) induces cosmological functors

\[
\begin{array}{c c c}
\mathcal{K}^\to \times \mathcal{K}^\to & \xrightarrow{\circ} & \mathcal{K}^\to \\
\downarrow F & \cong & \downarrow F \\
\mathcal{L}^\to \times \mathcal{L}^\to & \xrightarrow{\circ} & \mathcal{L}^\to \\
\end{array}
\]

that commute strictly with the codomain functors and up to isomorphism with the composition functor. Thus, a cosmological functor induces a double functor between the double categories of two-sided isofibrations, that strictly preserves vertical composition of functors and squares and preserves horizontal composition of spans and squares up to coherent natural isomorphism.

It follows that a cosmological functor \( F: \mathcal{K} \to \mathcal{L} \) induces a functor \( F: \text{Mod}(\mathcal{K}) \to \text{Mod}(\mathcal{L}) \) of virtual double categories of modules that preserves all of the structure strictly, since the multicategorical composition of module maps is derived from the strictly-defined vertical composition of squares in the double category of two-sided isofibrations. \( \square \)

Of crucial importance to its utility as a setting for formal category theory is the fact that the virtual double category of modules is a virtual equipment in the sense introduced by Cruttwell and Shulman \[32, \S 7\], which means that it satisfies the two further properties:

(i) For any module and pair of functors as displayed on the left, there exists a restriction module and cartesian cell as displayed on the right

\[
\begin{array}{c c c}
A' & B' & A' \xrightarrow{E(b,a)} B' \\
\downarrow a & \downarrow b & \Downarrow \rho \\
A & B & A \xrightarrow{E} B
\end{array}
\]

characterized by the universal property that any cell as displayed below-left factors uniquely through \( \rho \) as below-right:

\[
\begin{array}{c c c}
X_0 \xrightarrow{E_1} X_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} X_n \\
\downarrow a f & \Downarrow \exists! \Downarrow b g \\
A & \xrightarrow{E} B
\end{array} = \begin{array}{c c c}
X_0 \xrightarrow{E_1} X_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} X_n \\
\downarrow f & \Downarrow \exists! \Downarrow E(b,a) \\
A' & \xrightarrow{B'}
\end{array}
\]

The restriction module is defined by pulling back a module \( A \xrightarrow{E} B \) along functors \( a: A' \to A \) and \( b: B' \to B \). The simplicial pullback defining \( E(b,a) \) induces an equivalence of functor spaces

\[
\text{Fun}_{af,bg}(E_1 \times \cdots \times E_n, E) \simeq \text{Fun}_{fg}(E_1 \times \cdots \times E_n, E(b,a)),
\]

which gives rise to the universal property; see Proposition 8.2.1.
(ii) Every object $A$ admits a **unit** module equipped with a nullary **cocartesian** cell

$$
\begin{array}{c}
\xymatrix{\mathcal{A} \ar@{>->}[r]_\varepsilon & \mathcal{A} \\
\mathcal{A} \ar@{>->}[u]_{\mathbb{1}} & \mathcal{A} \ar@{>->}[u]_{\mathbb{1} \mathcal{A}}}
\end{array}
$$

satisfying the universal property that any cell in the virtual double category of modules whose horizontal source includes the object $A$, as displayed on the left

$$
\begin{array}{c}
\xymatrix{X \ar[r]^{E_1} & \cdots & A \ar[r]^{F_1} & \cdots & F_m \ar[r] & Y \\
\ar@{>->}[d]_f & & & & & & & & & & & & & & \ar@{>->}[d]_g \\
B \ar[r]_G & C}
\end{array}
\quad
\begin{array}{c}
\xymatrix{X \ar[r]^{E_1} & \cdots & A \ar[r]^{F_1} & \cdots & F_m \ar[r] & Y \\
\ar@{>->}[d]_f & & & & & & & & & & & & & & \ar@{>->}[d]_g \\
B \ar[r]_G & C}
\end{array}
$$

factors uniquely through $\varepsilon$ as displayed on the right. The unit module is the arrow $\infty$-category, given the notation $A \rightarrow A$ when considered as a module from $A$ to $A$. The universal property follows from the Yoneda lemma; see Proposition 8.2.4.

Lemma 11.2.1 extends to the virtual equipments of modules:

11.2.2. PROPOSITION. A cosmological functor $F: \mathcal{K} \rightarrow \mathcal{L}$ induces a functor $\mathcal{Mod}(\mathcal{K}) \rightarrow \mathcal{Mod}(\mathcal{L})$ of virtual equipments, preserving all of the structure.

**Proof.** In light of Lemma 11.2.1, it remains to consider unit and restriction modules and cells. It follows immediately from the constructions given in the proofs of Propositions 8.2.4 and 8.2.1 that these are preserved by cosmological functors:

$$
\begin{array}{c}
\xymatrix{A \ar@{>->}[d]_f & A \ar@{>->}[d]_g \\
\mathcal{A} \ar@{>->}[r]_{\mathbb{1}} & \mathcal{A}}
\end{array}
\quad
\begin{array}{c}
\xymatrix{E(b,a) \ar@{>->}[d]_f & E \ar@{>->}[d]_g \\
A' \times B' \ar@{>->}[r]_{(a,b)} & A \times B}
\end{array}
$$

The functors and natural transformations in the homotopy 2-category $\mathcal{K}$ embed into the virtual equipment $\mathcal{Mod}(\mathcal{K})$ in three ways. A functor $f: A \rightarrow B$ is represented as a vertical arrow and also by the horizontal modules $A \rightarrow B$ and $B \rightarrow A$, which behave like adjoints in a sense suitable to a virtual double category: the module $A \rightarrow B$ defines a companion and the module $B \rightarrow A$ defines a conjoint to the vertical arrow $f: A \rightarrow B$ (see 8.4.1, 8.4.4, and 8.4.6). These embeddings extend to natural transformations by Proposition 8.4.11: for any parallel pair of functors there are natural bijections between 2-cells in the homotopy 2-category

$$
\begin{array}{c}
\xymatrix{A \ar@{>->}[d]_f & B \\
B \ar@{>->}[u]_g}
\end{array}
$$
and cells in the virtual equipment of modules:

\[
\begin{array}{c}
\text{Hom}_B(B, f) \\
A \overset{A}{\longrightarrow} B \\
\downarrow \downarrow \downarrow \downarrow \\
A \overset{\text{Hom}_B(B, g)}{\longrightarrow} B
\end{array}
\quad \leftrightarrow \quad
\begin{array}{c}
\text{Hom}_A(\cdot, f) \\
A \overset{\rightarrow}{\longrightarrow} A \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
B \overset{\text{Hom}_B(\cdot, g)}{\longrightarrow} B
\end{array}
\quad \leftrightarrow \quad
\begin{array}{c}
\text{Hom}_B(\cdot, f) \\
A \overset{\rightarrow}{\longrightarrow} A \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
B \overset{\rightarrow}{\longrightarrow} B
\end{array}
\]

As remarked upon in Definition 8.4.12, as a consequence of these results, there are three locally-
fully-faithful homomorphisms from the homotopy 2-category \( \mathcal{K} \) into the virtual equipment \( \mathbb{M}
\text{od}(\mathcal{K}) \). The vertical embedding described by Propositions 8.3.18 sends the functors of \( \mathcal{K} \) to vertical arrows and the 2-cells to unary cells whose sources and targets are given by unit modules. The other two are the covariant and contravariant embeddings, respectively — embedding the homotopy 2-category into the substructure\(^1\) of \( \mathbb{M} \text{od}(\mathcal{K}) \) comprised only of unary cells whose vertical boundaries are identities. The modules in the image of the covariant embedding are the right representables and the modules in the image of the contravariant embedding are the left representables. We leave it to the reader to verify:

11.2.3. LEMMA. The functor of virtual equipments \( F: \mathbb{M} \text{od}(\mathcal{K}) \rightarrow \mathbb{M} \text{od}(\mathcal{L}) \) induced by a cosmological functor \( F: \mathcal{K} \rightarrow \mathcal{L} \) commutes with the covariant, contravariant, and vertical embeddings.

PROOF. Exercise 11.2.i. \( \Box \)

The theme of Chapter 9 could be summarized by saying that the virtual equipment of modules in an \( \infty \)-cosmos is a robust setting to develop the category theory of \( \infty \)-categories. On the one hand, it contains the homotopy 2-category of the \( \infty \)-cosmos, which was the setting for the results of Part I. It is also a very natural home to study \( \infty \)-categorical properties that are somewhat awkward to express in the homotopy 2-category. For instance, the weak 2-universal property of comma \( \infty \)-categories is now encoded by a bijection in Lemma 8.1.18: cells in the virtual equipment whose codomain is a comma module correspond bijectively to natural transformations of a particular form in the homotopy 2-category. Fibered equivalences of modules, as used to express the universal properties of adjunctions, limits, and colimits in Chapter 4, are now vertical isomorphisms in the virtual equipment between parallel modules. The virtual equipment also cleanly encodes the universal property of pointwise left and right Kan extensions.

In this chapter, we show that a cosmological biequivalence \( F: \mathcal{K} \Rightarrow \mathcal{L} \) induces a biequivalence of virtual equipments \( F: \mathbb{M} \text{od}(\mathcal{K}) \Rightarrow \mathbb{M} \text{od}(\mathcal{L}) \). We then explain the interpretation of this result: that the category theory of \( \infty \)-categories is preserved, reflected, and created by any “change-of-model” functor of this form.

We first elaborate on Proposition 10.3.1(ix).

11.2.4. PROPOSITION. A cosmological biequivalence \( F: \mathcal{K} \Rightarrow \mathcal{L} \) preserves, reflects, and creates modules:

(i) An isofibration \( (q, p): E \rightarrow A \times B \) is a module in \( \mathcal{K} \) if and only if \( (Fq, Fp): FE \rightarrow FA \times FB \) is a module in \( \mathcal{L} \).

(ii) A pair of modules \( A \Rightarrow B \) and \( A' \Rightarrow B \) are equivalent in \( \mathcal{K} \) if and only if \( FA \Rightarrow FB \) and \( FA' \Rightarrow FB \) define equivalent modules in \( \mathcal{L} \).

\( ^1\)This substructure is very nearly a bicategory, with horizontal composites of unary cells constructed as in Definition 8.3.16, except that compatible sequences of modules do not always admit a horizontal composite.
(iii) For every module $A' \xrightarrow{e} B'$ in $\mathcal{L}$ and every pair of $\infty$-categories $A, B$ in $\mathcal{K}$ with specified equivalences $FA \simeq A'$ and $FB \simeq B'$ there is a module $A \xrightarrow{F} B$ in $\mathcal{K}$ so that $FE$ is equivalent to $G$ over the pair of equivalences.

PROOF. The result of (i) was proven already in Proposition 10.3.1(ix). The result of (ii) follows easily from the fact that the induced cosmological biequivalence

$$
\begin{array}{c}
\mathcal{K}_A \text{Mod}(\mathcal{K})_B \xrightarrow{F} \mathcal{K}_A \text{Mod}(\mathcal{L})_{FB} \\
\mathcal{K}_A \text{Mod}(\mathcal{K})_B \xrightarrow{F} \mathcal{L}_{FA \times FB} \\
\end{array}
$$

preserves and reflects equivalences between objects.

For (iii), fix a pair of equivalences $FA \simeq A'$ and $FB \simeq B'$, defining an equivalence $e : A' \times B' \Rightarrow FA \times FB$, and consider the composite biequivalence

$$
\begin{array}{c}
\mathcal{K}_{A \times B} \xrightarrow{F} \mathcal{L}_{FA \times FB} \\
\end{array}
$$

given by Propositions 10.2.3 and 10.2.5. Consider a module $G \Rightarrow A' \times B'$. By essential surjectivity, there is an isofibration $E \Rightarrow A \times B$ whose image under this cosmological functor—the pullback of $FE \Rightarrow FA \times FB$ along $e : A' \times B' \Rightarrow FA \times FB$—defines an isofibration $(q, p) : E' \Rightarrow A' \times B'$ that is equivalent to $G$ in $\mathcal{L}'_{A' \times B'}$. It remains only to argue that $E$ defines a module from $A$ to $B$, which will follow, essentially as in the proof of (i), from the fact that $E' \simeq G$ defines a module from $A'$ to $B'$.

As the image $E'$ of $E$ is equivalent to a discrete object, Proposition 10.3.6(iii) tells us $E$ is discrete in $\mathcal{K}_{A \times B}$. The final step is to argue that the desired right adjoint to $E \Rightarrow \text{Hom}_B(B, p)$ is present in the image of the biequivalence $\mathcal{K}_{A \times B} \Rightarrow \mathcal{L}_{A' \times B'}$, and apply Theorem 11.1.1(i) to deduce its presence in $\mathcal{K}_{A \times B}$; a similar argument of course applies to the functor $E \Rightarrow \text{Hom}_A(q, A)$. To see this note that $F : \mathcal{K}_{A \times B} \Rightarrow \mathcal{L}_{FA \times FB}$ carries $\text{Hom}_B(B, p) \Rightarrow A \times B$ to $\text{Hom}_B(FB, Fp) \Rightarrow FA \times FB$. By (i), it suffices to argue that this functor has a right adjoint over $FA \times FB$. Applying Theorem 11.1.1(i) to the biequivalence $e^* : \mathcal{L}_{FA \times FB} \Rightarrow \mathcal{L}_{A' \times B'}$, this follows from the fact that $E' \Rightarrow \text{Hom}_B(B', p')$ has a right adjoint over $A' \times B'$.

\[\square\]

11.2.5. Proposition. Let $F : \mathcal{K} \Rightarrow \mathcal{L}$ be a cosmological biequivalence. Then a module $A \xrightarrow{E} B$ in $\mathcal{K}$ is right representable if and only if the module $FA \xrightarrow{FE} FB$ is right representable in $\mathcal{L}$, in which case, $F$ carries the representing functor $f : A \Rightarrow B$ in $\mathcal{K}$ to a representing functor $Ff : FA \Rightarrow FB$ in $\mathcal{L}$.

PROOF. To say that $A \xrightarrow{E} B$ is right representable in $\mathcal{K}$ is to say that there exists a functor $f : A \Rightarrow B$ together with an equivalence $E \simeq_{A \times B} \text{Hom}_B(B, f)$ of modules over $B$. If this is the case then any cosmological functor $F : \mathcal{K} \Rightarrow \mathcal{L}$ carries this to a fibered equivalence $FE \simeq_{FA \times FB} \text{Hom}_F(B, Ff)$, and hence the module $FA \Rightarrow FB$ is right-represented by $Ff : FA \Rightarrow FB$ in $\mathcal{L}$.

Conversely, if $FA \Rightarrow FB$ is right-represented by some functor $g : FA \Rightarrow FB$, then by Corollary 10.3.2(ii), there exists a functor $f : A \Rightarrow B$ in $\mathcal{K}$ so that $Ff \equiv g$ in $\mathcal{L}$. By Proposition 8.4.11, naturally isomorphic functors represent equivalent modules; that is, $\text{Hom}_F(B, g) \simeq_{FA \times FB} \text{Hom}_F(B, Ff)$. Thus $FE \simeq_{FA \times FB} \text{Hom}_F(B, Ff)$. By Proposition 11.2.4(ii), this fibered equivalence lifts along the cosmological functor $F : \mathcal{K}_{A \times B} \Rightarrow \mathcal{L}_{FA \times FB}$ to a fibered equivalence $E \simeq_{A \times B} \text{Hom}_B(B, f)$, which proves that $E$ is right represented by $f : A \Rightarrow B$ in $\mathcal{K}$.

\[\square\]
We have seen that cosmological functors induce functors of virtual equipments, preserving all the structure. When a cosmological functor is a biequivalence, the induced functor of virtual equipments also creates structure and reflects universal properties, on account of bijections we now enumerate.

11.2.6. Theorem (model independence of \(\infty\)-category theory). If \(F: \mathcal{K} \Rightarrow \mathcal{L}\) is a cosmological biequivalence, then the induced functor of virtual equipments

\[
F: \text{Mod}(\mathcal{K}) \Rightarrow \text{Mod}(\mathcal{L})
\]

defines a biequivalence of virtual equipments: i.e., it is

(i) bijective on equivalence classes of objects;
(ii) locally bijective on isomorphism classes of parallel vertical functors extending the bijection of (i);
(iii) locally bijective on equivalence classes of parallel modules extending the bijection of (ii);
(iv) locally bijective on cells extending the bijections of (i), (ii), and (iii).

Note further that if two \(\infty\)-cosmoi are connected by a finite zig-zag of biequivalences, then the bijections described in Theorem 11.2.6 compose.

Proof. Properties (i) and (ii) are restatements of Corollary 10.3.2(i) and (ii).

The local bijection (iii) follows immediately from Proposition 11.2.4 and the fact that for any pair of equivalences \(e: A' \times B' \Rightarrow FA \times FB\), the composite biequivalence

\[
\mathcal{K}_{/A \times B} \xrightarrow{F} \mathcal{L}_{/FA \times FB} \xrightarrow{e^*} \mathcal{L}_{/A' \times B'}
\]

preserves, reflects, and creates equivalences between objects, again by Corollary 10.3.2(i). Finally (iv) is an application of Corollary 10.3.2(ii) to this cosmological biequivalence. \(\square\)

Theorem 11.2.6 subsumes many of the model-independence statements we’ve established thusfar. For instance, the presence of adjunctions between \(\infty\)-categories and the existence of limits and colimits inside an \(\infty\)-category can both be encoded as an equivalence-invariant proposition in the virtual equipment of modules. Using Theorem 11.2.6, we can reprove Theorem 11.1.1 more efficiently.

Module Proof of Theorem 11.1.1. By Proposition 4.1.1, \(u: A \to B\) admits a left adjoint if and only if the module \(\text{Hom}_B(B,u)\) is contravariantly represented. Any representing functor in \(\mathcal{L}\) lifts up to isomorphism to define a functor \(f: B \to A\) in \(\mathcal{K}\) and now by Theorem 11.2.6(iii) there is an equivalence \(\text{Hom}_A(f, A) \simeq \text{Hom}_B(B, u)\) of modules from \(A\) to \(B\) in \(\mathcal{K}\) if and only if there is an equivalence \(\text{Hom}_{FA}(Ff, FA) \simeq \text{Hom}_{FB}(FB, Fu)\) of modules from \(FA\) to \(FB\) in \(\mathcal{L}\).

Similarly, a diagram \(d: 1 \to A^j\) admits a limit if and only if the module \(\text{Hom}_{A^j}(\Delta, d)\) is covariantly represented, and Proposition 11.2.5 or the argument just given completes the proof. \(\square\)

The model independence of pointwise right and left extensions, first proven in Proposition 10.3.8, can also be established as an elementary corollary of Theorem 11.2.6, by an argument left to Exercise 11.2.ii. Along the same lines, a biequivalence of virtual equipments preserves, reflects, and creates composites of modules:

11.2.7. Lemma. Let \(F: \mathcal{K} \Rightarrow \mathcal{L}\) be a cosmological biequivalence.

(i) Then a compatible sequence of modules in \(\mathcal{K}\) admits a composite in \(\text{Mod}(\mathcal{K})\) if and only if the image of this sequence admits a composite in \(\text{Mod}(\mathcal{L})\).

(ii) Hence, cosmological biequivalences preserve and reflect exact squares.
Proof. Via Definition 9.2.2, (ii) follows immediately from (i), so it remains only to show that a bijequivalence of virtual equipments $F: \text{Mod}(\mathcal{K}) \Rightarrow \text{Mod}(\mathcal{L})$ preserves, reflects, and creates composites of modules. To see that an $n$-ary composite cell $\mu: E_1 \times \cdots \times E_n \Rightarrow E$ in $\mathcal{K}$ is preserved, note that by Theorem 11.2.6(iv), any cell in $\text{Mod}(\mathcal{L})$ is isomorphic to a cell in the image of $F$: first replace the objects by equivalent ones in the image, then replace the vertical functors by naturally isomorphic ones in the image, then replace the modules by equivalent ones in the image over the specified equivalences between their $\infty$-categorical sources and targets, and then finally apply the local bijection (iv) to replace the cell in $\text{Mod}(\mathcal{L})$ by a unique cell in the image of $\text{Mod}(\mathcal{K})$ by composing with this data. Now, by local full and faithfulness and essential surjectivity, the universal property of the cocartesian cell $\mu: E_1 \times \cdots \times E_n \Rightarrow E$ implies that its image $F\mu: FE_1 \times \cdots \times FE_n \Rightarrow FE$ is again a cocartesian cell. Thus composites $E_1 \otimes \cdots \otimes E_n \simeq E$ are preserved by cosmological bijequivalences.

Now if $F\mu: FE_1 \times \cdots \times FE_n \Rightarrow FE$ is a composite, the fact that $F: \text{Mod}(\mathcal{K}) \Rightarrow \text{Mod}(\mathcal{L})$ is locally fully faithful implies immediately that $\mu: E_1 \times \cdots \times E_n \Rightarrow E$ is a composite; thus composites $FE_1 \otimes \cdots \otimes FE_n \simeq FE$ are reflected by cosmological bijequivalences.

Finally, suppose the sequence $FA_0 \Rightarrow FA_n$; since the compatible sequence of modules is in the image of $F$ the source and target $\infty$-categories of the composite module $G$ are as well. By Theorem 11.2.6(iii) there exists a module $A_0 \Rightarrow A_n$ in $\mathcal{K}$ so that $FE \simeq G$ as modules from $FA_0$ to $FA_n$. The cocartesian cell $FE_1 \times \cdots \times FE_n \Rightarrow G$ composes with the unary cell of this equivalence to define a cocartesian cell $FE_1 \times \cdots \times FE_n \Rightarrow FE$. By Theorem 11.2.6(iv), this lifts to an $n$-ary cell $E_1 \times \cdots \times E_n \Rightarrow E$ in $\text{Mod}(\mathcal{K})$. As we’ve just seen that cocartesianness of cells is reflected by bijequivalences $F: \text{Mod}(\mathcal{K}) \Rightarrow \text{Mod}(\mathcal{L})$, this completes the proof that composites are created by cosmological bijequivalences.

The upshot of Theorem 11.2.6, and the reason that we consider this as a proof of the model-independence of $\infty$-category theory, is that any statement about $\infty$-categories that can be encoded in the “language of a virtual equipment” is invariant under change of model. Our experience gives us some informal understanding of this language. It includes statements that characterize an $\infty$-category up to equivalence (such as a comma or arrow $\infty$-category) or a functor up to natural isomorphism (such as a left or right adjoint). Other model-independent statements are those which are expressible as an equivalence between modules (such as results concerning the left or right representability of modules) or in terms of the existence of a cell between modules with certain properties (such as in the case of pointwise extensions). But as we shall discover, this model-independent language can be described much more formally by taking advantage of a logical framework that we now introduce.

Exercises.

11.2.i. Exercise. Prove Lemma 11.2.3.

11.2.ii. Exercise. Use Theorem 11.2.6 to prove a module-theoretic proof that cosmological bijequivalences preserve, reflect, and create pointwise right and left extensions, and compare this argument with the proof of Proposition 10.3.8.

11.2.iii. Exercise. Prove that cosmological bijequivalences between cartesian closed $\infty$-cosmoi preserve and reflect initial and final functors.
11.3. First-Order Logic with Dependent Sorts

There is an important caveat to the invariance of $\infty$-category theory under change of model. If you pass from a complete Segal space to its underlying quasi-category and then back

$$CSS \xrightarrow{(-)_0} QCat \xrightarrow{\text{nerve}} CSS$$

the resulting complete Segal space is equivalent, but likely not equal to the one you started with. But even for ordinary 1-categories, not every statement about categories is invariant under equivalence of categories: “this category has a single object” is a famous counter-example. Similarly, not every statement about 2-categories is invariant under biequivalence. Consider, for instance, the statement that Proposition 1.4.5 proves for homotopy 2-categories: “this 2-category has a 2-terminal object.” If $F: C \Rightarrow D$ is a biequivalence between 2-categories and $D$ has a 2-terminal object $t$, then by essential surjectivity there is an $s \in C$ so that $Fs \simeq t$ in $D$. But the local equivalence property only supplies an equivalence

$$C(c,s) \simeq D(Fc,Fs) \simeq D(Fc,t) \cong 1,$$

making $s$ into a biterminal object but not necessarily a 2-terminal object.

The Model Independence Theorem 11.2.6 supplies a biequivalence between the virtual equipments of modules defined for any pair of biequivalence $\infty$-cosmoi. Since the important statements about $\infty$-categories can be expressed as properties of the virtual equipment, this biequivalence gives a mechanism by which results proven with one model of $\infty$-categories can be transferred to another model. But how can we be sure when a statement about $\infty$-categories that has been expressed in the language of virtual equipments is in fact invariant under a biequivalence of virtual equipments?

This sort of problem has a long history. Blanc [18] and Freyd [42] characterize the properties of ordinary categories that are invariant under equivalence of categories; see also Preller [89]. Makkai generalizes these results using his First-Order Logic with Dependent Sorts (FOLDS) [80] so that they extend to higher categorical structures, such as 2-categories and bicategories. In future work, we hope to provide a complete characterization of the statements about $\infty$-categories that are invariant under biequivalence of $\infty$-cosmoi, but our present aim is a result that is arguably more useful and much more easily obtained. In this section, we sketch the key ideas behind Makkai’s FOLDS framework; all the main concepts and results that follow are due to him, though we have made a few minor modifications in the definitions and depart somewhat in notation and terminology. In the next section, we apply this work to prove that any statement that can be expressed in the “language of virtual equipments,” as we define it in a very precise sense, gives rise to a model-independent statement about $\infty$-categories.

Makkai’s First-Order Logic with Dependent Sorts provides a formal language for writing mathematical sentences whose variables are structured according to a given signature. As the name suggests, sentences in FOLDS closely resemble the sentences of first-order logic, with an important new ingredient. Each variable is typed to belong to a specific sort and these sorts may depend on a finite family of compatibly-defined variables belonging to other sorts of lower degree. Universal and existential quantification is defined only over the variables of a single sort at a time, and the formula being quantified cannot contain any variables that depend on the variable being quantified over. Finally, relations, such as equality, are only permitted on the maximal sorts. For example, in the language of categories that will soon be introduced, it is permissible to write “for all objects $x$ and $y$ and for

Note our sought-for result is more similar to Makkai’s result about bicategories than Blanc and Freyd’s result about 1-categories, since we’re concerned about invariance change of model of higher categories rather than invariance under equivalence between $\infty$-categories in a given model.
all arrows \( f \) and \( g \) from \( x \) to \( y \), \( f \) equals \( g \),” asserting that the category is a pre-order. But it is not permissible to write “there exists an object \( x \) so that for all arrows \( h \), \( h \) equals \( 1_x \)” —asserting that the category is the terminal category—since the variable \( h \) and equality relation range over all arrows, rather than over the a single specified hom-set.

Before we introduce the FOLDS language, we must describe its signatures.

11.3.1. Definition. A simple inverse category is an inverse category \( \mathcal{I} \) in the sense of Definition C.1.16 with “finite fan-out,” meaning each object is the domain of only finitely many arrows. The objects of such categories can be assigned canonical degrees by examining the graph of non-identity arrows:

- objects which are not domains of any (non-identity) arrow have degree 0,
- while an object for which every (non-identity) “out-going arrow” has codomain of degree 0 is assigned degree 1, and
- continuing inductively, any object is assigned the minimal degree that exceeds the degree of the codomain of each of its (non-identity) out-going arrows.

This defines a canonical identity-reflecting functor \( \text{deg} : \mathcal{I} \to \omega^{op} \).

An object in a simple category is maximal if it is not the codomain of any non-identity arrow.

11.3.2. Definition. A FOLDS signature is a simple inverse category with a distinguished, possibly empty, set of maximal objects called “relation symbols.” The remaining objects are referred to as “kinds.”

Each non-identity arrow in a FOLDS signature indicates some dependency of a kind or relation symbol on other kinds, while commutativity conditions in the category encode compatibility conditions among the dependencies. In what follows, we distinguish the relation symbols by denoting them with a dot “.”

11.3.3. Example. The FOLDS signature \( \mathcal{I}_{\text{Cat}} \) for categories has kinds for the objects and arrows

\[
\begin{array}{c}
I \\
\downarrow i \\
\downarrow A \\
\downarrow O \\
\end{array}
\begin{array}{c}
T \\
\downarrow r \\
\downarrow t \\
\downarrow s \\
\end{array}
\begin{array}{c}
E \\
\downarrow c \\
\downarrow f \\
\end{array}
\]

with the composition relations

\[
\begin{align*}
s \cdot i &= t \cdot i \\
s \cdot c &= s \cdot t \\
s \cdot t &= s \cdot r \\
t \cdot c &= t \cdot r \\
t \cdot r &= t \cdot f \\
t \cdot f &= s \cdot r
\end{align*}
\]

In this instance, every maximal object is a relation symbol. The unary relation symbol \( I \) encodes identity arrows, while \( T \) witnesses ternary composition relations, and \( E \) expresses the equality of parallel arrows.

11.3.4. Example. The FOLDS signature \( \mathcal{I}_{2\text{-Cat}} \) for 2-categories has kinds for the 0-, 1-, and 2-cells, as well as for identity 1-cells and composition of 1-cells. In addition there are relation symbols for
equality of parallel 2-cells, identity 2-cells, and vertical and horizontal composition of 2-cells:

\[ T_2 \quad E \]
\[ H \quad C_2 \leftarrow I_2 \]
\[ T_1 \quad C_1 \leftarrow I_1 \]

\[ C_0 \]

The inverse category \( \mathcal{I}_{2\text{-}Cat} \) has the relations from the underlying 1-category

\[ s \cdot i = t \cdot i \quad s \cdot c = s \cdot \ell \quad t \cdot c = t \cdot r \quad t \cdot \ell = s \cdot r, \]

globularity relations

\[ s \cdot s = s \cdot t \quad t \cdot s = t \cdot t, \]

relations governing vertical composition and identities and equality between parallel 2-cells

\[ s \cdot i = t \cdot i \quad s \cdot c = s \cdot \ell \quad s \cdot \ell = s \cdot r \]
\[ t \cdot c = t \cdot r \quad t \cdot \ell = t \cdot r \]
\[ t \cdot \ell = s \cdot r \]

plus relations relating horizontal composition to composition of 1-cells

\[ s \cdot \ell = \ell \cdot s \quad s \cdot r = r \cdot s \quad s \cdot c = c \cdot s \]
\[ t \cdot \ell = \ell \cdot t \quad t \cdot r = r \cdot t \quad t \cdot c = c \cdot t. \]

11.3.5. Definition. For a FOLDS signature \( \mathcal{I} \), an \( \mathcal{I} \)-structure is a functor \( M : \mathcal{I} \rightarrow \textbf{Set} \) so that for each relation symbol \( R \in \mathcal{I} \), the map induced by the family of non-identity arrows with domain \( R \)

\[ M_R \longrightarrow \prod_{p : R \to K_p} MK_p \]

is a monomorphism.³

11.3.6. Example. For any small 1-category \( \mathcal{C} \), there is a naïve \( \mathcal{I}_{\text{Cat}} \)-structure \( N_{\mathcal{C}} : \mathcal{I}_{\text{Cat}} \rightarrow \textbf{Set} \) in which \( N_{\mathcal{C}} O \) is the set of objects and \( N_{\mathcal{C}} A \) is the set of arrows, with \( N_{\mathcal{C}} I, N_{\mathcal{C}} T, \) and \( N_{\mathcal{C}} E \) encoding the relations that detect identity arrows, commutative triangles, and equality between parallel arrows, respectively.

11.3.7. Example. For any small 2-category \( \mathcal{C} \), there is a naïve \( \mathcal{I}_{2\text{-Cat}} \)-structure \( N_{\mathcal{C}} : \mathcal{I}_{2\text{-Cat}} \rightarrow \textbf{Set} \) in which \( N_{\mathcal{C}} C_0, N_{\mathcal{C}} C_1, \) and \( N_{\mathcal{C}} C_2 \) are the sets of 0-, 1-, and 2-cells, and the remaining sets encode the intended relations. Alternatively, since \( I_1 \) and \( T_1 \) are not relation symbols in the FOLDS signature \( \mathcal{I}_{2\text{-Cat}} \), we may define a \( \mathcal{I}_{2\text{-Cat}} \)-structure \( M_{\mathcal{C}} \) by defining \( M_{\mathcal{C}} \) in the same way as \( N_{\mathcal{C}} \) on the kinds \( C_0, C_1, \) and \( C_2 \) and on the relation symbols \( I_2, T_2, \) and \( E \) but declaring:

³An alternative way to state this condition is to require that the components of the matching maps of Observation 11.3.8 for the relation symbols are monomorphisms; see Exercise 11.3.i.
\[\begin{array}{c}
\bullet \ M_C I_1 \text{ to be the set of endo-1-cells equipped with an isomorphism to an identity 1-cell;}
\bullet \ M_C T_1 \text{ to be the set of triangles of 1-cells inhabited by a specified invertible 2-cell;}
\bullet \ \text{and declaring the relation } M_C H \text{ to hold for a triple of 2-cells } \alpha : f \Rightarrow f', \beta : g \Rightarrow g', \gamma : h \Rightarrow h' \text{ together with invertible 2-cells } \delta : gf \cong h \text{ and } \epsilon : g'f' \cong h' \text{ just when the displayed pasting equality holds:}
\end{array}\]

\[\begin{array}{c}
a \xymatrix{ a \ar@/^/[rr]^{\alpha} & b \ar[r]^{\beta} & c \ar@/^/[ll]^{\gamma} }
\end{array}\]

We refer to \( M_C \) as the “saturated” \( I_{2, \text{Cat}} \)-structure and \( N_C \) as the “naïve” \( I_{2, \text{Cat}} \)-structure.

11.3.8. Observation (the fibers of the matching map). For each \( I \)-structure \( M : I \to \text{Set} \) and object \( K \in I \), either a kind or a relation symbol, there is a canonical matching map

\[\begin{array}{c}
M K \\
\xymatrix{ \partial^K M := \lim_{p : K \to K_p} M K_p } \\
\ar@{-->}[r]^{m^K} \\
\rightarrow \prod_{p : K \to K_p} M K_p
\end{array}\]

whose codomain is the matching object defined in Observation C.1.18. Note both the limit and the product are over non-identity arrows with domain \( K \), an implicit condition in similar constructions that follow. We think of a \( I \)-structure \( M \) as a structured set in which each set \( M K \) is further partitioned into the fibers of the matching map \( m^K : M K \to \partial^K M \).

We now describe Makkai’s “dependent sorts,” which are defined together with their variables by mutual recursion. The variables can be introduced purely syntactically, but we find it more intuitive to think of them as belonging to a context, this being a \( I \)-structure \( \Gamma \) in which the sets \( \Gamma K \) associated to each kind \( K \in I \) are disjoint.

11.3.9. Definition (sorts and their variables). Fix a FOLDS signature \( I \) and a context \( \Gamma : I \to \text{Set} \).

Each kind \( K \) of degree zero defines a sort, also denoted by \( K \), whose variables are the elements of the set \( \Gamma K \). Write “\( x : K \)” to mean that \( x \in \Gamma K \), i.e., that \( x \) is a variable belonging to the sort \( K \) in context \( \Gamma \).

For each kind \( K \) of degree one, the matching map takes the form \( m^K : \Gamma K \to \prod_{p : K \to K_p} \Gamma K_p \) where the product is over arrows \( K \to K_p \) in \( I \) with domain \( K \) and codomain of degree zero. For any family of variables \( \{ x_p : K_p \}_{p : K \to K_p} \), there is a sort \( K(x_p) \) whose variables are the elements of the fiber

\[\begin{array}{c}
\Gamma K(x_p) \\
\xymatrix{ \Gamma K(x_p) \ar[d]_{x} & \Gamma K \ar[d] \\
1 & \prod_{p : K \to K_p} \Gamma K_p \xymatrix{ \ar[r]^{(x_p)} & }
\end{array}\]

and are said to depend on the variables \( x_p : K_p \).
Finally, for a kind $K$ of higher degree, a family of variables $\{x_p : K_p\}_{p : K \to K}$ is compatible if $\langle x_p \rangle \in \prod_{p : K \to K} K_p$ belongs to the matching object $\partial^K \Gamma$. In practice, this means that the higher degree variables in the list depend on the lower degree ones in the way prescribed by the dependency relations in the FOLDS signature. For any compatible family of variables, there is a sort $K(x_p)$ whose variables are the elements of the fiber of the matching map $m^K$ over $\langle x_p \rangle \in \partial^K \Gamma$.

$$\begin{array}{cccc}
\Gamma K(x_p) & \longrightarrow & \Gamma K \\
\downarrow & & \downarrow \quad m^K \\
\{x_p\} & \longrightarrow & \partial^K \Gamma
\end{array}$$

By convention, the only variables that are explicitly listed in the specification of a sort are those of highest degree; the lower-degree variables that these variables depend on can be deduced from the sorts to which the highest degree variables belong.

11.3.10. **Example.** For the FOLDS signature $I_{Cat}$:
- There is a sort $O$.
- There is a sort $A(x, y)$ for any pair of variables $x, y : O$.

11.3.11. **Example.** For the FOLDS signature $I_{2-Cat}$:
- There is a sort $C_0$.
- There is a sort $C_1(x, y)$ for any pair of variables $x, y : C_0$.
- There is a sort $C_2(x, y, f, g)$ for any $x, y : C_0$ and $f, g : C_1(x, y)$. This sort is typically abbreviated by $C_2(f, g)$ with the implicit variables $x, y : C_0$ inferable from the sort in which the variables $f$ and $g$ live.

Using the same abbreviations:
- There is a sort $T_1(f)$ for any $x : C_0$ and $f : C_1(x, x)$.
- There is a sort $T_1(f, g, h)$ for any $x, y, z : C_0$ and $f : C_1(x, y), g : C_1(y, z), h : C_1(x, z)$.

We are now prepared to introduce the formulas and sentences of the formal language associated to a folds signature $I$. These are defined by recursion starting from the atomic formulæ, which are governed by the relation symbols. Again, we fix a FOLDS signature $I$ and a context $\Gamma : I \to Set$.

11.3.12. **Definition.** An atomic formula in the logic with dependent sorts is an entity of the form $\dot{R}(x_p)$, where $\dot{R}$ is a relation symbol and the variables $x_p : K_p(x_{qp})$ must define a compatible family, meaning that they define an element $\langle x_p \rangle \in \partial^R \Gamma$.

11.3.13. **Example.** In the FOLDS signature $I_{Cat}$, there is an atomic formula $\dot{T}(x, y, z, f, g, h)$, abbreviated $\dot{T}(f, g, h)$, for any $x, y, z : O$ and $f : A(x, y), g : A(y, z), h : A(x, z)$, which can be thought of as asserting the commutativity of the triangle formed by the arrows $f, g,$ and $h$.

11.3.14. **Digression.** A key idea in the FOLDS philosophy is that it should express a logic with restricted equality. This is visible in the FOLDS signatures $I_{Cat}$ and $I_{2-Cat}$, which include binary equality relation symbols on the kinds $A$ and $C_2$, but no similar equality predicates on the kinds $O, C_0, \text{and } C_1$ on which these depend. More precisely, the atomic formulæ $\dot{E}(f, g)$ for $I_{Cat}$ and $\dot{E}(\alpha, \beta)$ for $I_{2-Cat}$, may be used to express the equality of a parallel pair of arrows, since compatibility requires $f, g : A(x, y)$.
for some $x, y : O$, or the equality of parallel 2-cells, since compatibility requires $\alpha, \beta : C_1(f, g)$ for some $f, g : C_1(x, y)$ and some $x, y : O$. This sort of restriction is essential for the main theorem: that the validity of sentences expressed in the FOLDS are invariant under suitably-defined equivalences between structures.

In First-Order Logic with Dependent Sorts, one can quantify either universally or existentially only over the variables in a specified sort, provided the variables in the predicate under consideration do not depended on the variable being quantified over.

11.3.15. Definition. Formulae $\phi$ and their sets of free variables $\text{var}(\phi)$ are defined by simultaneous recursion:

- An atomic formula is a formula. The variables of $\hat{R}(x_p)$ are the $x_p$.

Compound formulae are defined inductively from other formulae via the following procedures:

- $\top, \bot$ are formulae, with $\text{var}(\top) := \text{var}(\bot) := \emptyset$.
- Formulae may be combined using the sentential connectives $\land, \lor, \rightarrow$, in which case the variables combine by unions: eg $\text{var}(\phi \land \psi) = \text{var}(\phi) \cup \text{var}(\psi)$.
- When $\phi$ is a formula and $x$ is a variable so that no variable in $\text{var}(\phi)$ depends on $x$—though $x \in \text{var}(\phi)$ is permitted—then $\forall x \phi$ and $\exists x \phi$ are well-formed formulas whose variables are given by the set $\text{var}(\forall x \phi) := \text{var}(\exists x \phi) := (\text{var}(\phi) - \{x\}) \cup \text{dep}(x)$ formed by removing $x$ from the variables of $\phi$ if it appears and then adding all the variables on which $x$ depends if they do not already appear.

When the set of variables in a formula is empty, we call the formula a sentence. Sentences are easiest to read when each quantified variable is declared with its sort, which expresses the range of the variable.

An evaluation of a $\mathcal{I}$-context $\Gamma$ in a $\mathcal{I}$-structure $M$ is given by a natural transformation $\alpha : \Gamma \to M$, which defines an interpretation of its variables, sending a variable $x : K(x_p)$ to an element in the corresponding fiber of $MK \to K^p M$. To interpret a particular formula $\phi$, it is not necessary to have specified an interpretation of the full context $\Gamma$. It suffices to merely specify the interpretation of its variables $\text{var}(\phi) \subset \Gamma$, which may be regarded as a context in their own right; see Exercise 11.3.ii.

Inductively in the complexity of a formula, we define what it means for a $\mathcal{I}$-structure $M$ to satisfy a formula $\phi$ under a given interpretation of its variables $\alpha : \text{var}(\phi) \to M$, a property we denote by $M \models \phi[\alpha]$.

11.3.16. Definition. An $\mathcal{I}$-structure $M$ satisfies an atomic formula $\hat{R}(x_p)$ under an interpretation $\alpha$ if and only if the tuple $\langle \alpha x_p \rangle \in \prod_{p: R \to K_p} MK_p$ lies in the subset $M \hat{R}$, in which case one writes $M \models \hat{R}[\alpha]$.

The sentences $\top$ and $\bot$ have no variables so their semantics are independent of interpretation. Any $\mathcal{I}$-structure satisfies $\top$ and no $\mathcal{I}$-structure satisfies $\bot$.

11.3.17. Definition. A $\mathcal{I}$-structure $M$ satisfies compound formulas built from $\phi$ and $\psi$ under an interpretation $\alpha : \text{var}(\phi) \cup \text{var}(\psi) \to M$ according to the rules:

- $M \models (\phi \land \psi)[\alpha]$ if and only if $M \models \phi[\alpha]$ and $M \models \psi[\alpha]$. 372
• $M \vDash (\phi \lor \psi)[\alpha]$ if and only if $M \vDash \phi[\alpha]$ or $M \vDash \psi[\alpha]$

• $M \vDash (\phi \rightarrow \psi)[\alpha]$ if and only if whenever $M \vDash \phi[\alpha]$ then also $M \vDash \psi[\alpha]$.

11.3.18. Definition. Consider a formula $\forall x \phi$ where $x : K(x_p)$ together with an interpretation

$$\alpha : \text{var}(\forall x \phi) \rightarrow M$$

in a $\mathcal{I}$-structure $M$; note that $x \notin \text{var}(\forall x \phi)$ so this does not give an interpretation of the variable $x$ itself. We say that $M$ satisfies $\forall x \phi$ under the interpretation $\alpha$ if for all $a$ in the fiber of $MK \rightarrow \partial^K M$ over $\langle \alpha x_p \rangle$, $M \vDash \phi(a/x)[\alpha]$. That is, $M \vDash \forall x \phi[\alpha]$ if any $a$ with appropriate dependencies can be substituted for $x$ in the interpretation of $\phi$ to yield a formula that $M$ satisfies.

Similarly $M$ satisfies $\exists x \phi$ under the interpretation $\alpha$ if there is some $a$ in the fiber of $MK \rightarrow \partial^K M$ over $\langle \alpha x_p \rangle$, so that $M \vDash \phi(a/x)[\alpha]$. That is, $M \vDash \exists x \phi[\alpha]$ if some $a$ with appropriate dependencies can be substituted for $x$ in the interpretation of $\phi$ to yield a formula that $M$ satisfies.

11.3.19. Example. In the language for $\mathcal{I}_{\text{Cat}}$, one can define a sentence that asserts the existence of an isomorphism between objects:

$$\exists x, y : O, \exists f : A(x, y), \exists g : A(y, x), \forall_{1_x} : A(x, x), \forall_{1_y} : A(y, y),$$

$$(1(1_x) \land 1(1_y)) \rightarrow (T(f, g, 1_x) \land T(g, f, 1_y))$$

but not equality between objects. Similarly, in the context given by $x, y : O$, the formula

$$\exists f : A(x, y), \exists g : A(y, x), \forall_{1_x} : A(x, x), \forall_{1_y} : A(y, y), (1(1_x) \land 1(1_y)) \rightarrow (T(f, g, 1_x) \land T(g, f, 1_y))$$

asserts the existence of an isomorphism between two objects specified by an interpretation.

11.3.20. Example. Modulo a change in notation, a similar sentence makes sense in the language for $\mathcal{I}_{2\text{-Cat}}$:

$$\exists x, y : C_0, \exists f : C_1(x, y), \exists g : C_1(y, x), \forall_{1_x} : C_1(x, x), \forall_{1_y} : C_1(y, y),$$

$$\forall \mu : I_1(1_x), \forall \upsilon : I_1(1_y), \exists \alpha : T_1(f, g, 1_x) \land \exists \beta : T_1(g, f, 1_y)$$

where “$\exists \alpha : T_1(f, g, 1_x)$” is shorthand for the formula “$\exists \alpha : T_1(f, g, 1_x).\top$.”

In the naïve $\mathcal{I}_{2\text{-Cat}}$-structure $\mathcal{N}_C$ associated to a 2-category $\mathcal{C}$, the interpretation again gives an isomorphism between objects, but in the saturated $\mathcal{I}_{2\text{-Cat}}$-structure $\mathcal{M}_C$ defined in Example 11.3.7, the interpretation now gives an equivalence between objects. By the construction of Example 11.3.27, formulae in the language of 2-categories that are interpreted in the $\mathcal{I}_{2\text{-Cat}}$-structures $\mathcal{M}_C$ will be invariant under biequivalence of 2-categories, though this result will not necessarily hold for when they are interpreted in the naïve $\mathcal{I}_{2\text{-Cat}}$-structures $\mathcal{N}_C$; see Exercise 11.3.vi.

We now give a criterion under which two $\mathcal{I}$-structures are guaranteed to satisfy the same formulas.

11.3.21. Definition. A natural transformation $\rho : M \rightarrow N$ of $\mathcal{I}$-structures is fiberwise surjective if for each $K \in \mathcal{I}$, either a relation symbol or a kind, the map to the pullback

$$\begin{array}{ccc}
MK & \xrightarrow{\rho_K} & NK \\
m_K & \downarrow & m_K \\
\partial^K M & \xrightarrow{\partial^K \rho} & \partial^K N
\end{array}$$

in the “matching square” for $K$ is an epimorphism.
In the terminology of §C.5, the fiberwise surjective maps are exactly those natural transformations that define **Reedy epimorphisms**, i.e., for which the relative matching maps (11.3.22) are epimorphisms.

11.3.23. **Lemma.** Let \( \rho : \mathcal{M} \to \mathcal{N} \) be fiberwise surjection between \( \mathcal{I} \)-structures. Then for each relation symbol \( \bar{R} \), the square

\[
\begin{array}{c}
\mathcal{M} \bar{R} \\
\downarrow m_R \\
\partial^R \mathcal{M}
\end{array} \quad \begin{array}{c}
\mathcal{N} \bar{R} \\
\downarrow m_R \\
\partial^R \mathcal{N}
\end{array} \quad \begin{array}{c}
\alpha \\
\downarrow \\
\gamma
\end{array}
\]

is a pullback.

**Proof.** Since \( \mathcal{M} \) and \( \mathcal{N} \) are \( \mathcal{I} \)-structures, the matching maps for the relation symbols of \( \mathcal{I} \) are monomorphisms; see Exercise 11.3.i. Thus, the induced map to the pullback is a monomorphism and by the fiberwise surjectivity hypothesis also an epimorphism. Thus, this map is an isomorphism in the category of sets, and so the square is a pullback. \( \square \)

11.3.24. **Example.** Any functor \( f : \mathcal{C} \to \mathcal{D} \) between 1-categories induces a natural transformation \( f : \mathcal{N}_C \to \mathcal{N}_D \) between the naïve \( \mathcal{I}_{\mathbf{Cat}} \)-structures of Example 11.3.6 that is fiberwise surjective if and only if the functor \( f \) is a surjective equivalence of categories: surjective on objects, full, and faithful.

11.3.25. **Definition.** Let \( \mathcal{I} \) be a FOLDS signature and let \( \Gamma : \mathcal{I} \to \mathbf{Set} \) be a context with given interpretations \( \alpha : \Gamma \to \mathcal{M} \) and \( \beta : \Gamma \to \mathcal{N} \) in \( \mathcal{I} \)-structures \( \mathcal{M}, \mathcal{N} : \mathcal{I} \to \mathbf{Set} \). The \( \mathcal{I} \)-structures \( \mathcal{M} \) and \( \mathcal{N} \) are **\( \mathcal{I} \)-equivalent in context \( \Gamma \)**, denoted \( \mathcal{M} \approx^\Gamma \mathcal{N} \), just when there is a diagram of fiberwise surjections \( \sigma \) and \( \rho \) between \( \mathcal{I} \)-structures under \( \Gamma \)

\[
\begin{array}{c}
\mathcal{M} \\
\downarrow \sigma & \alpha & \beta \\
\downarrow \gamma & \Gamma & \mathcal{N} \\
\downarrow \rho & \downarrow & \\
\mathcal{P}
\end{array}
\]

The relation \( \mathcal{I} \)-equivalent in context \( \Gamma \) is manifestly reflexive and symmetric. In fact, it is also transitive, as the reader may verify in Exercise 11.3.v.

11.3.26. **Example.** Consider an equivalence of categories \( f : \mathcal{C} \Rightarrow \mathcal{D} \) and form the iso-comma category of Definition 6.3.3 by the pullback.

\[
\begin{array}{c}
\mathcal{D} \times \mathcal{C} \\
\downarrow (q_1,q_0) \\
\mathcal{D} \times \mathcal{D}
\end{array} \quad \begin{array}{c}
\mathcal{D} \downarrow \alpha \\
\mathcal{D} \downarrow \downarrow (q_1,q_0) \\
\mathcal{D} \times \mathcal{D}
\end{array} \quad \begin{array}{c}
\mathcal{C} \end{array} \quad \begin{array}{c}
\mathcal{D} \times \mathcal{C} \quad \begin{array}{c}
\downarrow (q_1,q_0) \\
\mathcal{D} \times \mathcal{D}
\end{array}
\end{array}
\]

Since \( f \) is an equivalence of categories, the functors \( \mathcal{D} \leftarrow \mathcal{D} \times \mathcal{C} \to \mathcal{C} \) are surjective equivalences. It follows that the corresponding natural transformations between the naïve \( \mathcal{I}_{\mathbf{Cat}} \)-structures of Example
11.3.6 are fiberwise surjections

\[
\begin{array}{ccc}
N_D & \xrightarrow{q_0} & N_C \\
\downarrow & & \downarrow \\
N_C & \xleftarrow{q_1} & N_D
\end{array}
\]

defining an \(I_{\text{Cat}}\)-equivalence between \(N_C\) and \(N_D\).

11.3.27. Example. Consider a biequivalence of 2-categories \(F: C \to D\) and form the pseudo-comma 2-category \(\mathcal{P}\) whose

- objects are triples \((x \in C, x' \in D, a: Fx \Rightarrow x' \in D)\) with \(a\) an equivalence in \(D\),
- 1-cells \((x, x', a) \to (y, y', b)\) are triples

\[
\left(\begin{array}{ccc}
x \in C & x' \in D & Fx \xrightarrow{a} x' \\
\downarrow f & \downarrow f' & \downarrow \equiv_a \\
y \in D & y' \in D & Fy \xrightarrow{b} y'
\end{array}\right)
\]

- 2-cells \((f, f', \alpha) \Rightarrow (g, g', \beta)\) are given by a pair \((\gamma: f \Rightarrow g \in C, \delta: f' \Rightarrow g' \in D)\) so that

\[
\begin{array}{ccc}
Fx & \xrightarrow{a} & x' \\
Ff \xrightarrow{F\gamma} Fg \equiv \beta & \Rightarrow & Ff' \xrightarrow{\equiv_{\alpha}} Fg' \\
Fy & \xrightarrow{b} & y'
\end{array}
\]

The evident projections \(C \leftarrow \mathcal{P} \to D\) define 2-functors that are surjective on objects, full on 1-cells, and fully faithful on 2-cells. These induce fiberwise surjective natural transformations between the saturated \(I_{2\text{-Cat}}\)-structures of Example 11.3.7 defining a \(I_{2\text{-Cat}}\)-equivalence

\[
\begin{array}{ccc}
M_D & \xrightarrow{\rho} & M_C \\
\downarrow & & \downarrow \\
M_P & \xleftarrow{\sigma} & M_D
\end{array}
\]

Our interest in these notions is on account of the following theorem of Makkai:

11.3.28. Theorem. If \(M\) and \(N\) are \(I\)-equivalent in a context \(\Gamma\)

\[
\begin{array}{ccc}
\Gamma & \xrightarrow{\alpha} & M \\
\downarrow & & \downarrow \\
M & \xrightarrow{\gamma} & N \\
\downarrow & & \downarrow \\
P & \xleftarrow{\sigma} & \Gamma
\end{array}
\]

then \(M \models \phi[\alpha]\) if and only if \(M \models \phi[\beta]\) for all formulae \(\phi\) with \(\text{var}(\phi) \subset \Gamma\).
Proof. Since \( P \) is itself a \( \mathcal{I} \)-structure with an interpretation \( \gamma : \Gamma \to P \) of the variables defined by the context, it suffices to show that for any fiberwise surjection \( \sigma : P \to M \) then \( P \) and \( M \) satisfy the same formulas: \( P \models \phi[\gamma] \) if and only if \( M \models \phi[\sigma \gamma] \). This is proven by an induction over the complexity of the formula \( \phi \).

For the base case, consider an atomic formula \( \hat{R}(x_p) \) with an interpretation \( x_p : K \to P \). From the pullback of Lemma 11.3.23, \( x_p \in \partial K \mathcal{P} \) if and only if \( \sigma(x_p) \in \partial K \mathcal{M} \). Thus \( P \models \hat{R}[\gamma] \) if and only if \( M \models \hat{R}[\sigma \gamma] \).

Next consider the compound formulas \( \phi \land \psi, \phi \lor \psi \), and \( \phi \to \psi \) built from \( \phi \) and \( \psi \). Under the inductive hypothesis, we may assume that \( P \models \phi[\gamma] \) if and only if \( M \models \phi[\sigma \gamma] \) and similarly for \( \psi \). But now it follows immediately that \( P \models (\phi \land \psi)[\gamma] \) if and only if \( M \models (\phi \land \psi)[\sigma \gamma] \) and similarly for compound formulas \( \phi \lor \psi \) and \( \phi \to \psi \).

Finally, consider a formula of the form \( \forall x \phi \) where \( x : K \to P \). The interpretation \( \gamma : \text{var}(\forall x \phi) \to P \) defines an element in the matching object \( \gamma x_p \in \partial K \mathcal{P} \). The fiberwise surjectivity condition tells us that the map from \( PK \) to the pullback in the matching square for \( K \) displayed below-right is a surjection:

\[
\begin{array}{ccc}
PK(\gamma x_p) & \to & PK \\
\downarrow & & \downarrow \sigma_K \\
MK(\sigma \gamma x_p) & \to & MK \\
\downarrow & & \downarrow m_K \\
1 & \to & \partial K \mathcal{P} & \to & \partial K \mathcal{M}
\end{array}
\]

By composing pullbacks, it follows that we get a surjection from the fiber of \( PK \to \partial K \mathcal{P} \) over \( \gamma x_p \) to the fiber of \( MK \to \partial K \mathcal{M} \) over \( \sigma \gamma x_p \). In particular, if for all \( a \) in the fiber of \( PK \to \partial K \mathcal{P} \), \( P \models \phi(a/x)[\gamma] \), then by the inductive hypothesis \( M \models \phi(a/x)[\sigma \gamma] \). Since every element \( b \) in the fiber of \( MK \to \partial K \mathcal{M} \) equals \( \sigma a \) for some \( a \) in the fiber of \( PK \to \partial K \mathcal{P} \), this tells us that \( P \models (\forall x \phi)[\gamma] \) if and only if \( M \models (\forall x \phi)[\sigma \gamma] \).

Similarly, for \( \exists x \phi, P \models (\exists x \phi)[\gamma] \) if and only if there exists some \( a \) in the fiber so that \( P \models \phi(a/x)[\gamma] \). But this holds if and only if \( M \models \phi(a/x)[\sigma \gamma] \) and, by naturality of \( \sigma \), \( \sigma a \) lives in the appropriate fiber. So if \( P \models (\exists x \phi)[\gamma] \) then \( M \models (\exists x \phi)[\sigma \gamma] \). Conversely if \( M \models (\exists x \phi)[\sigma \gamma] \), then there is some \( b \) in the fiber of \( MK \to \partial K \mathcal{M} \) over \( \sigma \gamma x_p \) so that \( M \models \phi(b/x)[\sigma \gamma] \). By fiberwise surjectivity, there is some \( a \) in the fiber of \( PK \to \partial K \mathcal{P} \) over \( \gamma x_p \) so that \( \sigma a = b \). By the inductive hypothesis \( P \models \phi(a/x)[\gamma] \) if and only if \( M \models (\exists x \phi)[\sigma \gamma] \), so we see that if \( M \models (\exists x \phi)[\sigma \gamma] \) then \( P \models (\exists x \phi)[\gamma] \).

\( \square \)

Exercises.

11.3.i. Exercise. Let \( \mathcal{I} \) be a FOLDS signature with relation symbol \( \hat{R} \in \mathcal{I} \) and let \( M : \mathcal{I} \to Set \) be any functor. Prove that the map

\[
\prod_p \mathcal{MK}_p \to \mathcal{MR}
\]

of Definition 11.3.5 is a monomorphism if and only if the matching map

\[
\lim_p \mathcal{MK}_p \to \partial K \mathcal{M} := \lim_p \mathcal{MK}_p
\]

of Observation C.1.18 is a monomorphism.
11.3.ii. **Exercise.**

(i) Show that if \( \phi \) is any formula then \( \text{var}(\phi) \) is closed under dependences: if \( x \in \text{var}(\phi) \) then \( \text{dep}(x) \subseteq \text{var}(\phi) \).

(ii) Show that the variables \( \text{var}(\phi) \) defined for a particular formula in context \( \Gamma \) define a subcontext \( \text{var}(\phi) \subseteq \Gamma \).

11.3.iii. **Exercise.** An object \( s \) in a 2-category \( \mathcal{C} \) is **biterminal** if for every \( c \in \mathcal{C} \), the hom-category \( \mathcal{C}(c, s) \cong \mathbf{1} \) is a contractible groupoid. Write a sentence in the language of 2-categories that asserts that the 2-category has a biterminal object.

11.3.iv. **Exercise.** Connect the result of Lemma 11.3.23 to the statement that
\[
M \models \hat{R}[\alpha] \iff N \models \phi[\rho\alpha]
\]
for some interpretation \( \alpha : \Gamma \to M \).

11.3.v. **Exercise.** Verify that the relation defined by Definition 11.3.25 is transitive by composing the spans formed by the fiberwise surjections.

11.3.vi. **Exercise.** Use a sentence or formula along the lines considered in Example 11.3.20 and the result of Theorem 11.3.28 to show that there exist biequivalent 2-categories \( \mathcal{C} \) and \( \mathcal{D} \) so that the naïve \( I_2\text{-Cat} \)-structures \( N_\mathcal{C} \) and \( N_\mathcal{D} \) are not \( I_2\text{-Cat} \)-equivalent in an appropriate context.

### 11.4. A Language for Model-Independent \( \infty \)-Category Theory

Our aim in this section is to apply Makkai’s Theorem 11.3.28 to prove that statements about \( \infty \)-categories that are written in the language of a virtual equipment, defined for a FOLDS signature \( I_{\mathcal{VE}} \) that we will presently introduce, are invariant under change-of-model. Our first task is to define the FOLDS signature \( I_{\mathcal{VE}} \) so that FOLDS-structures satisfying a certain family of axioms are virtual equipments in the sense of Cruttwell and Shulman.

11.4.1. **Definition.** The FOLDS signature \( I_{\mathcal{V}G\mathcal{C}at} \) for virtual double categories has kinds for the objects, vertical arrows, horizontal modules, and \( n \)-ary cells for each \( n \geq 0 \).

![Diagram](image)

Each arrow and each module has a source object and target object. Each \( n \)-ary cell has a left boundary arrow, a right boundary arrow, a target module, and \( n \) source modules. The source and target objects of this boundary data must be compatible in the way specified by the composition relations
\[
\begin{align*}
s \cdot \ell &= s \cdot s_1 & s \cdot r &= t \cdot s_n & t \cdot s_k &= s \cdot s_{k+1}, & 1 \leq k < n \\
t \cdot \ell &= s \cdot t & t \cdot r &= t \cdot t
\end{align*}
\]
in the case \( n \geq 1 \). For 0-arrow cells, the relation
\[
s \cdot \ell = s \cdot r
\]
replaces the relations involving the absent source modules.

Each sort of \( n \)-ary cells supports a binary equality relation:

\[
\ell \cdot \ell = \ell \cdot r \quad r \cdot \ell = r \cdot r \quad t \cdot \ell = t \cdot r \quad s_k \cdot \ell = s_k \cdot r
\]

Put another way, equal cells must have the same boundary type. In addition, in a virtual double category, each module has a specified unary identity cell whose vertical sources and targets are identity arrows. The relation symbol \( I_C \) satisfies the composition relation
\[
s \cdot i = t \cdot i \quad \ell \cdot i = i \cdot \ell \quad r \cdot i = i \cdot r
\]
which require that the source and target modules coincide and the left and right vertical arrows are identities.

Finally, a virtual double category has an underlying category of objects and vertical arrows. In the FOLDS signature for 1-categories, the arrow sort \( A \) bears a ternary relation
\[
T
\]
whose three maps identify the left, right, and composite arrow of a commuting triangle. In the FOLDS signature for virtual double categories, as in the FOLDS signature for 2-categories, we are forced to introduce \( T \) as a kind, rather than as a relation symbol, since it is mapped to from another relation symbol that we now describe.
For each partition $n_1 + \cdots + n_k = n$ there is a $(k + 4)$-ary relation symbols $\hat{T}_{n_1, \ldots, n_k}$ with the indicated dependencies:

$$\begin{align*}
  s_1 \cdot s_j &= s_{n_1 + \cdots + n_{j-1} + i} \cdot c \\
  t \cdot s_j &= s_j \cdot t \\
  t \cdot t &= t \cdot c \\
  \ell \cdot \ell &= \ell \cdot s_1 \\
  \ell \cdot r &= r \cdot \ell \\
  r \cdot \ell &= \ell \cdot r \\
  r \cdot r &= r \cdot c \\
  c \cdot \ell &= \ell \cdot c \\
  c \cdot r &= r \cdot c
\end{align*}$$

Here $\hat{T}_{n_1, \ldots, n_k}$ is the relation that witnesses that a given $n$-cell is a composite of $k$ source cells with arities $n_1, \ldots, n_k$ into a given target $k$-cell. Such a composition depends also on the specification of left and right commutative triangles of vertical arrows, as described by the composition relations.

11.4.2. Definition. The FOLDS signature for a virtual equipment $\mathcal{I}_{\mathbb{V}{\mathbb{E}}}$ extends the FOLDS signature for virtual double categories with two additional unary relation symbols $U$ and $R$ identifying the
nullary unit modules and unary restriction modules:

\[ \begin{align*}
&\dot{E}_0 \\
&\dot{E}_1 \\
&\dot{E}_2 \\
&\dot{E}_n \\
&\dot{U} \\
&i_C \\
&\dot{C}_0 \\
&\dot{C}_1 \\
&\dot{C}_2 \\
&\ldots \\
&\dot{C}_n \\
&A \\
&M \\
&O
\end{align*} \]

The left and right vertical arrows of a unit module are identities on the same object, as expressed by the composition relations

\[ \ell \cdot i = i \cdot o = r \cdot i. \]

There are no composition relations imposed on the boundary of the unary restriction cell. This data comprises the FOLDS signature for virtual equipments a la Cruttwell and Shulman.

In a naïve manner, any virtual equipment defines a \( \mathcal{I}_{\mathcal{V}E} \)-structure, with the functor \( \mathcal{I}_{\mathcal{V}E} \to \text{Set} \) assigning each kind or relation symbol its intended interpretation. As the virtual equipments of greatest interest are large, the \( \mathcal{I}_{\mathcal{V}E} \)-structures will be large as well. But as was the case for 2-categories, the objects \( I_A \) and \( T \) are not relation symbols in the FOLDS signature for virtual equipments. Thus, in a \( \mathcal{I}_{\mathcal{V}E} \)-structure \( M \), the maps \( MI_A \to MA \) and \( MT \to MA \times MA \times MA \) need not be monomorphisms. This gives us the flexibility to convert a virtual equipment into a \( \mathcal{I}_{\mathcal{V}E} \)-structure in a more “saturated” manner. In fact, in analogy with Example 11.3.27 and Exercise 11.3.vi, it will be necessary to “saturate” the \( \mathcal{I}_{\mathcal{V}E} \)-structures associated to virtual equipments in this manner to prove one of our desired results: that a biequivalence of virtual equipments gives rise to a \( \mathcal{I}_{\mathcal{V}E} \)-equivalence, in the sense of Definition 11.3.25. Recall, for instance from Corollary 10.3.2, that a biequivalence of 2-categories is only surjective on objects up to equivalence and surjective on 1-cells up to 2-isomorphism modulo those equivalences, which is why invertible 2-cells enter the picture in our specification of saturated structures.

11.4.3. RECOLLECTION. Recall from Proposition 8.3.18 that any virtual equipment contains a vertical 2-category whose objects are the objects of the virtual equipment, whose arrows are the vertical arrows, and whose 2-cells are those unary cells

\[ \begin{align*}
&\begin{array}{c}
A \\
\downarrow^g
\end{array} \\
&\begin{array}{c}
\downarrow^f
\end{array}
\end{align*} \]
whose horizontal boundary arrows are given by the unit modules. Confusingly, the “horizontal composition” of 2-cells is captured by the vertical composition of unary cells in the virtual equipment, while the “vertical composition” of 2-cells is captured by the horizontal composition operation defined by Definition 8.3.16. In particular, we describe a unary cell in the vertical 2-category as “invertible” when it is invertible in the usual sense for a 2-cell in a 2-category, that is for the horizontal composition operation of unary cells between unit modules in the virtual equipment; note that the vertical boundary 1-cells of an invertible cell in the vertical 2-category need not be invertible in any sense.

In fact, the construction described in Definition 8.3.16 generalizes as follows. Given any cell in the virtual equipment and pair of cells in the vertical 2-category as displayed

\[
\begin{align*}
A_0 & \xrightarrow{\text{Hom}_{A_0}} A_0 \xrightarrow{E_1} A_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} A_n \xrightarrow{\text{Hom}_{A_n}} A_n \\
B & \xrightarrow{\text{Hom}_B} B \xrightarrow{f} B \xrightarrow{\text{Hom}_C} C \xrightarrow{g} C
\end{align*}
\]  

there is a unique “horizontal composite” cell with boundary

\[
\begin{align*}
A_0 & \xrightarrow{E_1} A_1 \xrightarrow{E_2} \cdots \xrightarrow{E_n} A_n \\
B & \xrightarrow{f} B \xrightarrow{g} C
\end{align*}
\]

satisfying the analogue of the pasting equality (8.3.17) defined relative to the canonical composition cells of Lemma 8.3.10. In what follows, we abuse notation and write an expression like (11.4.4) to denote the composite cell (11.4.5).

In the virtual equipment \( \mathbb{M}od(\mathcal{K}) \) of modules in an \( \infty \)-cosmos \( \mathcal{K} \), this vertical 2-category is isomorphic to the homotopy 2-category \( \mathcal{H} \mathcal{K} \). Since our intention is to apply the following construction in that context, we borrow notation from the homotopy 2-category when it is simpler to read, for instance writing \( \alpha : f \Rightarrow g \) for a unary cell in the vertical 2-category whose right boundary is \( f \) and whose left boundary is \( g \).

11.4.6. Definition. For any virtual equipment \( \mathcal{C} \), there is a \( \mathcal{I}_{\mathcal{VE}} \)-structure \( \mathcal{M}_\mathcal{C} \) in which:

- The sets \( \mathcal{M}_\mathcal{C}O, \mathcal{M}_\mathcal{C}A, \mathcal{M}_\mathcal{C}M, \) and \( \mathcal{M}_\mathcal{C}C_n \) for each \( n \geq 0 \) are given their naïve interpretations as the sets of objects, vertical arrows, horizontal modules, and \( n \)-ary cells of \( \mathcal{C} \).
- The binary relations \( E_n \) encode equality between parallel cells.
- The relation \( R \) encodes all unary cells that are cartesian, satisfying the universal property that characterizes the restriction cells.
- For any \( i : \mathcal{M}_\mathcal{C}A(X, X) \), the set \( \mathcal{M}_\mathcal{C}I_A(i) \) is the set of invertible cells \( \alpha : id_X \cong i \) in the vertical 2-category.
- For any \( i : \mathcal{M}_\mathcal{C}A(X, X), \alpha : \mathcal{M}_\mathcal{C}I_A(i), j : \mathcal{M}_\mathcal{C}A(Y, Y), \beta : \mathcal{M}_\mathcal{C}I_A(j), E : \mathcal{M}_\mathcal{C}M(X, Y), \) and \( \nu : \mathcal{M}_\mathcal{C}C_1(i, j, E, E) \), the set \( \mathcal{M}_\mathcal{C}I_C(\nu) \) is a singleton if the identity cell \( id_E \) associated to the
module $E$ equals the horizontal composite cell

$$
\begin{array}{c}
\xymatrix{X \ar[r]^{\text{Hom}_X} & X \ar[r]^E & Y \ar[r]^{\text{Hom}_Y} & Y = & X \ar[r]^E & Y} \\
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \\
\xymatrix{X \ar[r]^{\text{Hom}_X} & X \ar[r]^E & Y \ar[r]^{\text{Hom}_Y} & Y}
\end{array}
$$

and is empty otherwise.

- For any $i : MCA(X, X)$, $\alpha : MC_A(i)$, $H : MC_M(X, X)$, and $\theta : MCO(i, i, H)$, the set $MCU(i, \theta)$ is a singleton if the nullary composite cell

$$
\begin{array}{c}
\xymatrix{X \ar[r]^{\text{Hom}_X} & X = X \ar[r]^{\text{Hom}_X} & X} \\
\downarrow \downarrow \downarrow \downarrow \\
\xymatrix{X \ar[r]^{\text{Hom}_X} & X \ar[r]^{H} & X}
\end{array}
$$

is cocartesian and is empty otherwise.

- For any $f : MCA(X, Y)$, $g : MCA(Y, Z)$, and $h : MCA(X, Z)$, the set $MC(T(f, g, h)$ is the set of invertible cells $\gamma: gf \cong h$ in the vertical 2-category.

- For any $n_1 + \cdots + n_k = n$ and cells

$$
\begin{array}{c}
\xymatrix{A_0 \ar[r]^{E_{11}, \ldots, E_{1n_1}} & A_1 \ar[r]^{E_{21}, \ldots, E_{2n_2}} & \cdots \ar[r]^{E_{kn_k}, \ldots, E_{kn_k}} & A_k} \\
B_0 \ar[r]^{f_0} & B_1 \ar[r]^{f_1} & \cdots \ar[r]^{f_k} & B_n \\
C \ar[r]^{G} & D
\end{array}
\quad \text{and}
\quad
\begin{array}{c}
\xymatrix{A_0 \ar[r]^{E_{11}, \ldots, E_{1n_1}} & A_1 \ar[r]^{E_{21}, \ldots, E_{2n_2}} & \cdots \ar[r]^{E_{kn_k}, \ldots, E_{kn_k}} & A_k} \\
C \ar[r]^{G} & D
\end{array}
$$

and isomorphisms $\gamma: T(f_0, g, k)$ and $\delta: T(f_k, h, \ell)$, the set $MCT_{n_1, \ldots, n_k}(\alpha_1, \ldots, \alpha_k, \beta, \epsilon, \gamma, \delta)$ is a singleton if $\epsilon$ equals the composite

$$
\begin{array}{c}
\xymatrix{A_0 \ar[r]^{\text{Hom}_{A_0}} & A_0 \ar[r]^{\text{Hom}_{A_0}} & A_1 \ar[r]^{\text{Hom}_{A_1}} & \cdots \ar[r]^{\text{Hom}_{A_k}} & A_k} \\
B_0 \ar[r]^{f_0} & B_1 \ar[r]^{f_1} & \cdots \ar[r]^{f_k} & B_n \\
C \ar[r]^{\text{Hom}_{C}} & C \ar[r]^{\text{Hom}_{C}} & D \ar[r]^{\text{Hom}_{D}} & D
\end{array}
$$

and is empty otherwise.

We write $M_K : I_{VE} \to Set$ for the $I_{VE}$-structure obtained by applying the construction of Definition 11.4.6 to the virtual equipment of modules $\text{Mod}(K)$.

11.4.7. Lemma. Any functor of virtual equipments $F : C \to D$ induces a natural transformation $F : MC \to MD$ between $I_{VE}$-structures. Hence, any cosmological functor $F : K \to L$ induces a natural transformation $F : MK \to ML$ between $I_{VE}$-structures.
**Proof.** Recall that a functor of virtual equipments is a map of virtual double categories that preserves all the structure, including unit and restriction cells. It follows that application of \( F \) directly defines the components of a natural transformation \( F : \mathcal{M}_\mathcal{K} \to \mathcal{M}_\mathcal{L} \) between the corresponding \( \mathcal{I}_{\mathcal{VE}} \)-structures. By Proposition 11.2.2, a cosmological functor \( F : \mathcal{K} \to \mathcal{L} \) induces a functor \( F : \text{Mod}(\mathcal{K}) \to \text{Mod}(\mathcal{L}) \) of virtual equipments, which by Lemma 11.2.3 respects the vertical embeddings of the homotopy 2-categories, so these observations apply in particular in that case. \( \square \)

11.4.8. **Proposition.** Consider a pair of \( \infty \)-cosmoi connected by a cosmological functor \( F : \mathcal{K} \to \mathcal{L} \).

(i) If \( F : \mathcal{K} \to \mathcal{L} \) is a cosmological biequivalence, then there exists a pair of fiberwise surjections between the corresponding \( \mathcal{I}_{\mathcal{VE}} \)-structures:

\[
\begin{array}{c}
\mathcal{P} \\
\downarrow \rho \\
\mathcal{M}_\mathcal{K} & \quad \alpha \\
\mathcal{M}_\mathcal{L} \end{array}
\]

(ii) Moreover, if the induced map between \( \mathcal{I}_{\mathcal{VE}} \)-structures preserves the given interpretations of a context \( \Gamma \):

\[
\begin{array}{c}
\mathcal{M}_\mathcal{K} \\
\downarrow F \\
\mathcal{M}_\mathcal{L} \\
\uparrow \beta \\
\\Gamma \end{array}
\]

then the fiberwise surjections constructed in (i) defines a \( \mathcal{I}_{\mathcal{VE}} \)-equivalence in context \( \Gamma \):

\[
\begin{array}{c}
\mathcal{M}_\mathcal{K} \\
\downarrow \gamma \\
\mathcal{P} & \quad \sigma \\
\mathcal{M}_\mathcal{L} \end{array}
\]

**Proof.** We apply the same strategy used in Examples 11.3.26 and 11.3.27, forming a structure that we call the **pseudo-comma virtual equipment** \( \mathcal{P} \) associated to the functor of virtual equipments \( F : \text{Mod}(\mathcal{K}) \to \text{Mod}(\mathcal{L}) \).\(^4\) The \( \mathcal{I}_{\mathcal{VE}} \)-structure \( \mathcal{P} \) is then defined to be \( \mathcal{M}_\mathcal{P} \) and \( \sigma \) and \( \rho \) are the evident projections. We then argue that these maps are fiberwise surjective under the hypothesis that \( F \) is a biequivalence of virtual equipments.

The **pseudo-comma virtual equipment** \( \mathcal{P} \) associated to \( F : \text{Mod}(\mathcal{K}) \to \text{Mod}(\mathcal{L}) \) has

- objects given by triples \( (A \in \mathcal{K}, A' \in \mathcal{L}, a : FA \Rightarrow A' \in \mathcal{L}) \) where \( a \) is an equivalence.

\(^4\)A pseudo-comma virtual equipment can be defined for any functor (or more generally cospan of functors) between virtual equipments in exactly the same manner, but where it simplifies notation we refer also to structures in the \( \infty \)-cosmoi and their homotopy 2-categories.
• vertical arrows \((A, A', a) \rightarrow (B, B', b)\) given by triples

\[
\begin{aligned}
\begin{array}{c}
A \\
f \\
\end{array} & \in \mathcal{K}, \\
\begin{array}{c}
A' \\
f' \\
\end{array} & \in \mathcal{L}, \\
\begin{array}{c}
FA \\
\sim \\
\end{array} & \rightarrow \begin{array}{c}
A' \\
\end{array}, \\
\begin{array}{c}
B \\
\approx_t \\
\end{array} & \rightarrow \begin{array}{c}
B' \\
\end{array}, \\
\begin{array}{c}
FB \\
\sim_b \\
\end{array} & \rightarrow \begin{array}{c}
B' \\
\end{array}
\end{array}
\]

• modules \((A, A', a) \longrightarrow (B, B', b)\) given by triples

\[
\begin{aligned}
\begin{array}{c}
A \\
\rightarrow \\
\end{array} & \in \mathcal{K}, \\
\begin{array}{c}
A' \\
f' \\
\end{array} & \rightarrow \begin{array}{c}
B' \\
\in \mathcal{L}, \\
\end{array}, \\
\begin{array}{c}
FA \\
\sim \\
\end{array} & \rightarrow \begin{array}{c}
FB \\
\in \text{Mod}(\mathcal{L})
\end{array}
\end{aligned}
\]

where \(e\) is a cartesian cell,

• \(n\)-ary cells given by a pair of \(n\)-ary cells \(\mu\) in \(\mathcal{K}\) and \(v\) in \(\mathcal{L}\) so that the composite cells formed from their boundary data are equal:

Note the objects and vertical arrows form a category: indeed it is in the underlying 1-category of the pseudo comma 2-category of Example 11.3.27 for the 2-functor \(F: \mathcal{K} \rightarrow \mathcal{L}\). Each module \((E, E', \epsilon) : (A, A', a) \longrightarrow (B, B', b)\) has an identity cell whose components are the identity cells \(id_E \in \mathcal{K}\) and \(id_E' \in \mathcal{L}\). Composition of cells is inherited from \(\text{Mod}(\mathcal{K})\) and \(\text{Mod}(\mathcal{L})\), though we leave it to the reader to verify that the required pasting equation between the composite cells defined in this manner by drawing a very large diagram. This makes \(\mathcal{P}\) into a virtual double category.

In fact \(\mathcal{P}\) is a virtual equipment. Each object \((A, A', a)\) admits a nullary unit cell whose vertical arrows are both taken to be the identity \((id_A, id_{A'}, id_a)\) and whose component cells in \(\mathcal{K}\) and \(\mathcal{L}\) are the
unit cells for $A$ and $A'$. Finally, any diagram comprised of two vertical arrows and a horizontal module

$$ \begin{array}{ccc}
(X, X', x) & (Y, Y', y) \\
(f, f', \alpha) \downarrow & \downarrow (g, g', \beta) \\
(A, A', a) \rightarrow (B, B', b)
\end{array} $$

can be completed to a unary cartesian cell

$$ \begin{array}{cccc}
F_X & F_Y & F_{g(f)} & F_{g(f')}
\end{array} $$

where $\rho$ and $\rho'$ are the restriction cells in $\mathcal{K}$ and $\mathcal{L}$ respectively, and the cell $\zeta$ is defined by factoring the left-hand pasting diagram below through the cartesian cell $\rho'$.

$$ \begin{array}{cccc}
F_X & F_Y & F_{g(f)} & F_{g(f')}
\end{array} $$

Since $\epsilon, F, \rho,$ and $\rho'$ are cartesian cells in $\mathcal{L}$, $\zeta$ is a cartesian cell as well, making $(E(g, f), E'(g', f'), \zeta)$ into a module in $\mathcal{P}$. This makes the virtual double category $\mathcal{P}$ into a virtual equipment so that the evident forgetful functors to $\text{Mod}(\mathcal{K})$ and $\text{Mod}(\mathcal{L})$ define functors of virtual equipments.

By Lemma 11.4.7 we obtain a diagram of $I_{\mathcal{VE}}$-structures and natural transformations

$$ \begin{array}{cccc}
M_{\mathcal{P}} & M_{\mathcal{K}} & \sigma \\
M_{\mathcal{K}} & M_{\mathcal{L}} & \rho
\end{array} $$

Finally, when $F : \text{Mod}(\mathcal{K}) \rightarrow \text{Mod}(\mathcal{L})$ is a biequivalence of virtual equipments, satisfying the properties enumerated in Theorem 11.2.6, the forgetful functors

$$ \begin{array}{ccc}
\text{Mod}(\mathcal{K}) & \rightarrow & \text{Mod}(\mathcal{L})
\end{array} $$

are surjective on objects, full on vertical arrows, full on horizontal modules, and fully faithful on cells, and reflect unit cells and restriction cells. It follows that the maps $\sigma$ and $\rho$ are fiberwise surjective.

Finally, if $F : M_{\mathcal{K}} \rightarrow M_{\mathcal{L}}$ strictly preserves the interpretations of a context $\Gamma$ in $\text{Mod}(\mathcal{K})$ and $\text{Mod}(\mathcal{L})$, then it is possible to simultaneously lift these interpretations along $\sigma$ and $\rho$ to an interpretation $\gamma : \Gamma \rightarrow \mathcal{P}$. This can easily be verified inductively in the $I_{\mathcal{VE}}$-structure $\Gamma$. For a variable $x : O,$
if \( a(x) = A \) and \( \beta(x) = FA \), then define \( \gamma(x) := (A, FA, \text{id}_{FA}) \). The definition of \( \gamma \) at higher-degree variables is similar, with the missing data chosen to be the appropriate identities in \( \mathcal{L} \).

Combining these results we obtained the desired corollary:

11.4.9. **COROLLARY** (a language for model-independent \( \infty \)-category theory). *Formulae in the language of virtual equipments are invariant under biequivalence of \( \infty \)-cosmoi.*

**PROOF.** Consider a formula \( \phi \) in the language of a virtual equipment. By Proposition 11.4.8 and Exercise 11.3.v, biequivalent \( \infty \)-cosmoi define \( I_{\mathcal{VE}} \)-structures as proscribed by Definition 11.4.6 that are \( I_{\mathcal{VE}} \)-equivalent in the context defined by the variables of \( \phi \). By Theorem 11.3.28, such \( I_{\mathcal{VE}} \)-structures satisfy the same formulas.

We conclude with some examples.

11.4.10. **EXAMPLE.** In the context of a pair of objects \( a, b : O \) and an arrow \( u : A(a, b) \), the formula

\[
\exists f : A(b, a), \forall i_a : A(a, a), \forall \omega_a : I_A(i_a), \forall u_a : M(a, a), \forall i_a : C_0(i_a, i_u u_a), U(i_u u_a),
\]

\[
\forall b : A(b, b), \forall \omega_b : I_A(i_b), \forall u_b : M(b, b), \forall i_b : C_0(i_b, i_u u_b), U(i_u u_b),
\]

\[
\exists m : M(a, b), \exists \rho_f : C_1(i_a, f, m, u_a), \exists \rho_u : C_1(u, i_b, m, u_b), \check{R}(\rho_f) \land \check{R}(\rho_u),
\]

which may be paraphrased as “there is an arrow \( f \) so that the covariant representation of \( u \) is equivalent to the contravariant representation of \( f \),” asserts the existence of a left adjoint to \( u \).

11.4.11. **EXAMPLE.** In the context of three objects \( a, b, c : O \) and a span of arrows \( k : A(a, b) \) and \( f : A(a, c) \), we claim that the formula

\[
\exists r : A(b, c), \forall i_a : A(a, a), \forall \omega_a : I_A(i_a), \forall i_b : A(b, b), \forall \omega_b : I_A(i_b), \forall i_c : A(c, c), \forall \omega_c : I_A(i_c),
\]

\[
\forall u_b : M(b, b), \forall i_b : C_0(i_b, i_u u_b), U(i_u u_b), \forall u_c : M(c, c), \forall i_c : C_0(i_c, i_u u_c), U(i_u u_c),
\]

\[
\forall k : M(a, b), \forall f : M(a, c), \forall r : M(b, c),
\]

\[
\forall \rho : C_1(k, i_b, k, u_b), \forall \rho_f : C_1(f, i_c, f, u_c), \forall \rho_r : C_1(r, i_c, r, u_c), \check{R}(\rho_k) \land \check{R}(\rho_f) \land \check{R}(\rho_r),
\]

\[
\forall \tau_a : T(i_a, i_a, i_a), \forall \tau_c : T(i_c, i_c, i_c), \forall i_{i_{i_{i_k}}}, C_1(i_a, i_b, k, u_b), I_c(i_{i_{i_{i_k}}}),
\]

\[
\forall v : C_2(i_a, i_c, k, r, f), \forall x : O, \forall m : M(b, x), \forall n : M(x, c),
\]

\[
\forall \alpha : C_3(i_a, i_c, k, m, n, f), (\exists \mu : C_2(i_b, i_c, m, n, r), T_{1, 2}(i_{i_a}, i_{i_c}, i_{i_k}, m, n, f) \land \check{T}(i_{i_a}, i_{i_c}, i_{i_k}, m, n, f) \Rightarrow \check{T}_{1, 2}(i_{i_a}, i_{i_c}, i_{i_k}, m, n, f))
\]

\[
(v \land \xi : C_2(i_a, i_c, m, n, r), \check{T}_{1, 2}(i_{i_a}, i_{i_c}, i_{i_k}, m, n, f) \land \check{T}_{1, 2}(i_{i_a}, i_{i_c}, i_{i_k}, m, n, f) \Rightarrow \check{T}_{2}(\xi, \xi))
\]

asserts the existence of a pointwise right extension \( \psi : rk \Rightarrow f \).

Here we’ve taken advantage of a simplification provided in the virtual equipment of modules. Recall from Theorem 9.3.3 that a natural transformation \( \nu : rk \Rightarrow f \) defines a pointwise right extension if the corresponding binary cell, also denoted \( \nu \) in the formula above, defines a right extension in the virtual equipment of modules. By Definition 9.1.2, this means that the binary cell \( \nu \) must enjoy a unique factorization property for all cells whose target module is the covariant representation of \( f \) and whose source sequence of modules starts from the covariant representation of \( k \).

In the above formula we do not quantify over a compatible sequence of modules from “\( b \)” to “\( c \)” of arbitrary length, instead quantifying over a single intermediate object “\( x \)” and a pair of modules “\( m : M(b, x) \)” and “\( n : M(x, c) \).” We can make this simplification on account of Remark 8.3.12, which tells us that any compatible sequence of modules \( E_1 \times \cdots \times E_\xi \) in the source of a cell can be replaced.
by a compatible sequence of two modules. Here the object ”x” is the summit of the composite two-sided fibration formed by composing the spans that encode the modules $E_1, \ldots, E_\ell$, while the modules ”m” and “n” are respectively the contravariant and covariant representable modules associated to the legs of that composite span.

Special cases of this statement and its dual define limits and colimits of diagrams of $\infty$-categories, as well as many other concepts.

**Exercises.**

11.4.i. **Exercise.** Express the axioms for a virtual equipment in the language of a virtual equipment defined relative to the FOLDS signature $I_{\mathcal{VE}}$. For instance, the axiom that asserts that for every module and compatible pair of vertical arrows there exists a unary restriction cell is expressed by the sentence:

$$\forall x, y, a, b : O, \forall f : A(x, a), \forall g : A(y, b), \forall m : M(a, b),$$

$$\exists m(g, f) : M(x, y), \exists \rho : C_1(f, g, m(g, f), m), \mathcal{R}(\rho)$$

11.4.ii. **Exercise.** Prove that the functor $F : \text{Mod}(\mathcal{K}) \to \text{Mod}(\mathcal{L})$ of virtual equipments defined by a cosmological functor $F : \mathcal{K} \to \mathcal{L}$ defines a natural transformation $F : M_\mathcal{K} \to M_\mathcal{L}$ between the $I_{\mathcal{VE}}$-structures of Lemma 11.4.7.
CHAPTER 12

Applications of Model Independence

In this chapter, we establish some elementary properties of a certain class of ∞-cosmoi we might call ∞-cosmoi of (∞,1)-categories, by which we mean ∞-cosmoi that are biequivalent to QC\textit{a}t. By Proposition 10.2.2 an ∞-cosmos \( \mathcal{K} \) is an ∞-cosmos of (∞,1)-categories if and only if its underlying quasi-category functor \( (-)_0 : \mathcal{K} \to QC\textit{a}t \) is a biequivalence — meaning that every quasi-category is equivalent to the underlying quasi-category of an ∞-category in \( \mathcal{K} \) and that for any \( A, B \in \mathcal{K} \) the map on functor spaces

\[
\text{Fun}(A, B) \xrightarrow{(-)_0} \text{Fun}(A_0, B_0) \leftrightarrow \text{Fun}(A, B) \times \text{Fun}(1, A) \xrightarrow{\circ} \text{Fun}(1, B)
\]

defined by transposing the composition map in \( \mathcal{K} \) is an equivalence of quasi-categories. Several examples of ∞-cosmoi of this form are established in §E.2.

The aim is to illustrate how the model-independence theorem can be used to combine synthetic and analytic techniques to prove results concerning any family of biequivalent ∞-cosmoi. In what follows we appeal to the explicit model of (∞,1)-categories as quasi-categories to supply analytic proofs of certain key results — for instance, that a functor defines an equivalence of quasi-categories just when it is fully faithful and essential surjective in a suitable sense. We then explain how the model-independence theorem can be used to transfer these results to biequivalent ∞-cosmoi. In this instance, we are able to conclude that any functor defines an equivalence of (∞,1)-categories just when it is fully faithful and essentially surjective, even though we can’t translate the specific proof of the quasi-categorical case of this result. We then apply this result to further develop the synthetic theory of ∞-cosmoi of (∞,1)-categories.

Many of the results in this chapter have been alluded to previously in this text and indeed their proofs could have appeared earlier. The reason for the delay is that in the presence of the results of Chapters 10 and 11 their conclusions apply more broadly, to all ∞-cosmoi of (∞,1)-categories, not just in the quasi-categorical case. In particular, we discuss some special features of the ∞-cosmos of quasi-categories, proving in particular that universal properties in this ∞-cosmos are determined pointwise, again appealing to model-independence to generalize this result to other ∞-cosmoi of (∞,1)-categories.

To warm up in §12.1, we define opposite (∞,1)-categories and the ∞-groupoid core of an (∞,1)-category. In practice, these notions are easily accessible in any model of choice, but our aim is to illustrate the general procedure of transferring ∞-categorical structures between biequivalent ∞-cosmoi in a relatively elementary setting. In §12.2, we establish a large suite of results which combine to express the pointwise-generation of various universal properties in an ∞-cosmos of (∞,1)-categories. Finally, in §12.3 we cite a more sophisticated result from the (∞,1)-categorical literature concerning the exponentiability of cartesian and cocartesian fibrations and use this to tie up a loose end from Chapter 9: namely we reduce the existence of pointwise right and left extensions to the presence of certain limits or colimits. Since the indexing shapes for these limits and colimits vary with the elements in
the domain of the pointwise extension, this result relies on the pointwise-determination of universal properties established in §12.2. Along the way we also extend the calculus of modules in $\infty$-cosmoi of $(\infty,1)$-categories, showing that the right extensions and right liftings of Definition 9.1.2 always exist, defining “homs” between modules to complement their “tensor products.”

12.1. Opposite $(\infty,1)$-Categories and $\infty$-Groupoid Cores

The construction of the co-dual of an $\infty$-cosmos in Definition 1.2.25 makes use of the construction of the opposite of a simplicial set. Recall that the opposite of a simplicial set $X: \Delta^{\text{op}} \to \mathbf{Set}$ is obtained by precomposing with the identity-on-objects involution $(-)^{\text{op}}: \Delta \to \Delta$ that reverses the ordering of the elements in each ordinal $[n] \in \Delta$. Precomposition with $(-)^{\text{op}}$ defines a functor $(-)^{\text{op}}: s\mathbf{Set} \to s\mathbf{Set}$ which carries a simplicial set $X$ to its opposite simplicial set $X^{\text{op}}$. We start by exploring the role played by this operation in the $\infty$-cosmos of quasi-categories and then investigate a related operation on other $\infty$-cosmoi of $\infty$-categories.

12.1.1. Lemma. If $X$ is a quasi-category, then $X^{\text{op}}$ is a quasi-category.

Proof. The lifting problem below-left is solved by the lifting problem below-right

\[
\begin{array}{ccc}
\Lambda^{k}[n] & \longrightarrow & X^{\text{op}} \\
\downarrow & & \downarrow \\
\Delta[n] & \longrightarrow & X
\end{array}
\]

\[
\begin{array}{ccc}
\Lambda^{n-k}[n] & \longrightarrow & X \\
\downarrow & & \downarrow \\
\Delta[n] & \longrightarrow & X^{\text{op}}
\end{array}
\]

12.1.2. Definition. For a quasi-category $A$, its opposite quasi-category $A^{\text{op}}$ is the simplicial set defined by “reversing the ordering of the vertices in each simplex.”

12.1.3. Lemma. The opposite quasi-category construction defines a cosmological biequivalence $(-)^{\text{op}}: \mathbf{QCat} \to \mathbf{QCat}^{\text{co}}$ that acts on functor spaces via a natural isomorphism

\[
\text{Fun}(A, B) \cong \text{Fun}(A^{\text{op}}, B^{\text{op}})^{\text{op}}.
\]

Proof. The isomorphism $\text{Fun}(A, B) \cong \text{Fun}(A^{\text{op}}, B^{\text{op}})^{\text{op}}$ is best understood at the level of simplices: the simplicial maps $A \times \Delta[n] \to B$ that define $n$-simplices in the left-hand functor space correspond bijectively via the isomorphism $(-)^{\text{op}}: s\mathbf{Set} \to s\mathbf{Set}$ to simplicial maps $A^{\text{op}} \times \Delta[n]^{\text{op}} \to B^{\text{op}}$, these defining the $n$-simplices in the right-hand functor space.

By an extension of the proof of Lemma 12.1.1, the opposite of an isofibration is an isofibration. The conical limits in $\mathbf{QCat}$, being defined pointwise in $\mathbf{Set}$, are preserved by restriction along the functor $(-)^{\text{op}}: \Delta \to \Delta$. Simplicial cotensors are also preserved: for a quasi-category $B$ and a simplicial set $X$, $(B^{X})^{\text{op}} \cong (B^{\text{op}})^{X^{\text{op}}}$, which accords with the general construction of the cotensor of $B^{\text{op}} \in \mathbf{QCat}^{\text{co}}$ with a simplicial set $X$ as noted in Definition 1.2.25. Alternatively, one can use the natural isomorphism $\text{Fun}(A, B) \cong \text{Fun}(A^{\text{op}}, B^{\text{op}})^{\text{op}}$ to directly verify that the quasi-category $(B^{X})^{\text{op}}$ has the universal property that characterizes the cotensor in $\mathbf{QCat}^{\text{co}}$. □

This extends the usual construction of the opposite of a 1-category and the corresponding 2-functor $(-)^{\text{op}}: \mathbf{Cat} \to \mathbf{Cat}^{\text{co}}$; see Exercise B.2.iii. On account of the explicitness of the construction given in Definition 12.1.2, the opposite of a quasi-category is defined up to isomorphism. By contrast, without any additional hypotheses, we’ll only be able to define the opposite of an $\infty$-category in a biequivalent
∞-cosmos up to equivalence.¹ While at first this may seem undesirable, it is arguably morally correct to give the definition in this manner, since from the model-independent point of view, the ∞-category itself ought only be considered up to equivalence.

12.1.4. Definition. Let $A$ be an ∞-category in an ∞-cosmos $\mathcal{K}$ that is biequivalent to $\mathcal{QC}at$. Define the opposite ∞-category $A^{\text{op}}$ to be any ∞-category in $\mathcal{K}$ whose underlying quasi-category is $A_0^{\text{op}}$.

By Proposition 10.2.2 and Corollary 10.3.2, the underlying quasi-category functor $(-)_0 : \mathcal{K} \to \mathcal{QC}at$ is bijective on equivalence classes of objects; hence Definition 12.1.4 is well-defined up to equivalence:

12.1.5. Proposition. Let $\mathcal{K}$ be an ∞-cosmos of (∞,1)-categories.

   (i) Any ∞-category in $\mathcal{K}$ has an opposite, well-defined up to equivalence.
   (ii) Any specified choices in (i) assembles into a quasi-pseudofunctor and biequivalence $(-)^{\text{op}} : \mathcal{K} \to \mathcal{K}^{\text{co}}$ defined as the composite of the zig-zag of cosmological biequivalences

   $\mathcal{K} \overset{(-)_0}{\longrightarrow} \mathcal{QC}at \overset{(-)^{\text{op}}}{\leftarrow} \mathcal{K}_{\text{co}} \overset{(-)_0}{\longrightarrow} \mathcal{QC}at^{\text{co}}$

   (iii) In particular, for any ∞-categories $A, B \in \mathcal{K}$, there is an equivalence $\text{Fun}(A, B) \simeq \text{Fun}(A^{\text{op}}, B^{\text{op}})^{\text{op}}$ that is quasi-pseudonatural in $A$ and in $B$.

Proof. The underlying quasi-category functor $(-)_0 : \mathcal{K} \to \mathcal{QC}at$ is bijective on equivalence classes of objects by Proposition 10.2.2 and Corollary 10.3.2. Since the underlying quasi-category $A_0$ of any ∞-category $A \in \mathcal{K}$ has an opposite, this proves that $A$ must have an opposite as well, and thus Definition 12.1.4 is well-defined up to equivalence, with $A^{\text{op}}$ characterized by the equivalence of quasi-categories

$\text{Fun}(1, A^{\text{op}}) \simeq \text{Fun}(1, A)^{\text{op}}$.

For ∞-categories $A$ and $B$, by construction $(A^{\text{op}})_0 \simeq (A_0)^{\text{op}}$ and $(B^{\text{op}})_0 \simeq (B_0)^{\text{op}}$. Composing with these equivalences, the biequivalence $(-)_0 : \mathcal{K} \to \mathcal{QC}at$ provides local equivalences of quasi-categories:

$\text{Fun}(A, B) \overset{(-)_0}{\longrightarrow} \text{Fun}(A_0, B_0) \overset{(-)^{\text{op}}}{\leftarrow} \text{Fun}(A^{\text{op}}, B^{\text{op}}) \overset{(-)^{\text{op}}}{\longrightarrow} \text{Fun}((A^{\text{op}})_0, (B^{\text{op}})_0) \overset{(-)^{\text{op}}}{\leftarrow} \text{Fun}((A_0)^{\text{op}}, (B_0)^{\text{op}})$

which compose to define the desired equivalence in such a way that the square commutes up to a homotopy coherent isomorphism. In order for these equivalences to define the action on functor spaces of a quasi-pseudofunctor, we follow the construction of Corollary 10.4.17 described in the proof of Proposition 10.4.16 and choose adjoint equivalence inverses to the horizontal simplicial natural equivalences, applying Lemma 10.4.15. This also proves the quasi-pseudonaturality statement of (iii), via Lemma 10.4.12.

¹In every model of (∞,1)-categories that we are aware of, there is in fact a strictly defined op-involution, and one can verify that these analytically-defined opposite ∞-categories are compatible with the standard change-of-model functors. However, the benefits of this additional strictness might not be worth the effort in verifying the strict compatibility of the opposite ∞-category construction in each instance.
On account of the equivalence \( \text{Fun}(A, B) \cong \text{Fun}(A^{\text{op}}, B^{\text{op}})^{\text{op}} \), a functor between \((\infty, 1)\)-categories \( f: A \to B \) has an opposite functor \( f^{\text{op}}: A^{\text{op}} \to B^{\text{op}} \), well-defined up to isomorphism once the domain and codomain \((\infty, 1)\)-categories have been fixed. Similarly, a natural transformation between parallel functors has an opposite obtained by applying the pseudofunctor \((-)^{\text{op}}: \mathcal{K} \xrightarrow{\sim} \mathcal{K}^{\text{op}}\) that underlies the quasi-pseudofunctor of Proposition 12.1.5. Furthermore:

12.1.6. Lemma. Let \( \mathcal{K} \) be an \((\infty, 1)\)-cosmos of \((\infty, 1)\)-categories.

(i) For any \((\infty, 1)\)-category \( A \) and simplicial set \( U \), \( (A^U)^{\text{op}} \cong (A^{\text{op}})^U^{\text{op}} \).

(ii) For any functors \( f: B \to A \) and \( g: C \to A \), \( \text{Hom}_A(f, g)^{\text{op}} \cong \text{Hom}_{A^{\text{op}}}(g^{\text{op}}, f^{\text{op}}) \) over \( B^{\text{op}} \times C^{\text{op}} \).

Proof. We have a quasi-pseudonatural equivalence:

\[
\text{Fun}(X, (A^U)^{\text{op}}) \cong \text{Fun}(X^{\text{op}}, A^U)^{\text{op}} \quad \begin{array}{l}
\cong (\text{Fun}(X^{\text{op}}, A)^U)^{\text{op}} \quad \text{by } 12.1.5(iii)
\cong (\text{Fun}(X^{\text{op}}, A)^{\text{op}})^{U^{\text{op}}} \quad \text{by } 12.1.3
\cong \text{Fun}(X, (A^{\text{op}})^U)^{\text{op}} \quad \text{by } 12.1.5(iii)
\cong \text{Fun}(X, (A^{\text{op}})^{U^{\text{op}}}) \quad \text{by } (1.2.7).
\end{array}
\]

Hence, by Lemma 10.4.14, \( (A^U)^{\text{op}} \cong (A^{\text{op}})^U^{\text{op}} \).

The second statement is a consequence of a more general result: that any quasi-pseudofunctorial biequivalence, such as \((-)^{\text{op}}: \mathcal{K} \xrightarrow{\sim} \mathcal{K}^{\text{op}}\) established in Proposition 12.1.5, preserves and reflects comma \((\infty, 1)\)-categories. Alternatively, since the quasi-pseudofunctorial biequivalence under consideration here, is defined as a zig zag of cosmological biequivalences, the result follows from the fact that cosmological biequivalences themselves preserve and reflect comma \((\infty, 1)\)-categories, as observed in Proposition 10.3.6(v).

The next result provides another perspective on “appeals to duality” where facts about colimits of diagrams in an \((\infty, 1)\)-cosmos \( \mathcal{K} \) were deduced from corresponding proofs about limits in \( \mathcal{K}^{\text{co}} \), and similarly results about cartesian fibrations were interpreted in \( \mathcal{K}^{\text{co}} \) to conclude the corresponding results about cocartesian fibrations in \( \mathcal{K} \).

12.1.7. Proposition. Let \( \mathcal{K} \) be an \((\infty, 1)\)-cosmos of \((\infty, 1)\)-categories.

(i) A \( J \)-shaped family of diagrams in \( A \) has a colimit if and only if the transposed \( J^{\text{op}} \)-shaped family of diagrams in \( A^{\text{op}} \) has a limit.

(ii) A functor \( p: E \to B \) defines a cartesian fibration if and only if \( p^{\text{op}}: E^{\text{op}} \to B^{\text{op}} \) defines a cocartesian fibration.

Note that if \( p: E \to B \) is an isofibration, it is always possible to choose a functor \( p^{\text{op}}: E^{\text{op}} \to B^{\text{op}} \) that is again an isofibration, perhaps by changing the choice of total space \( E^{\text{op}} \).
Proof. By Lemma 12.1.6, a $J$-shaped family of diagrams $d: D \to A$ transposes to define a $J^{\text{op}}$-shaped family of diagrams $d^{\text{op}}: D^{\text{op}} \to (A^{\text{op}})^{J^{\text{op}}}$. By Proposition 4.3.1, $d$ admits a colimit in $A$ if and only if there is an equivalence of comma $\infty$-categories

$$\text{Hom}_{A^{\text{op}}}(d, \Delta) \simeq \text{Hom}_{A}(c, A),$$

in which case the representing functor $c: D \to A$ defines the colimit functor.

By Lemma 12.1.6, such an equivalence exists if and only if

$$\text{Hom}_{(A^{\text{op}})^{J^{\text{op}}}}(\Delta, d^{\text{op}}) \simeq D^{\text{op}} \times A^{\text{op}} \text{Hom}_{A^{\text{op}}}(A^{\text{op}}, c^{\text{op}}),$$

an equivalence which, by Proposition 4.3.1, characterizes the limit functor $c^{\text{op}}: D^{\text{op}} \to A^{\text{op}}$.

The second statement is proven similarly. By Theorem 5.2.10, $p: E \to B$ defines a cartesian fibration if and only if the induced functor $p^\gamma: E^2 \to \text{Hom}_B(B, p)$ admits a right adjoint whose counit is an isomorphism. By applying the quasi-pseudofunctorial biequivalence $(-)^{\text{op}}: \mathcal{K} \simeq \mathcal{K}^{\text{op}}$, this adjunction exists if and only if the opposite functor admits a left adjoint whose unit is an isomorphism, and Lemma 12.1.6 identifies this opposite functor as $p^{\text{op}} \circ \gamma \simeq p^{\text{op}} \circ \gamma : (E^{\text{op}})^2 \to \text{Hom}_{B^{\text{op}}}(p^{\text{op}}, B^{\text{op}})$. By the dual of Theorem 5.2.10, such an adjunction exists if and only if $p^{\text{op}}: E^{\text{op}} \to B^{\text{op}}$ is a cocartesian fibration. □

12.1.8. Remark (on dual co/cartesian fibrations). Cartesian fibrations $p: E \to B$ in an $\infty$-cosmos of $(\infty,1)$-categories in $\mathcal{K}$, correspond to homotopy coherent diagrams indexed by the underlying quasi-category of $\mathcal{K}$, valued in the quasi-category of $(\infty,1)$-categories in $\mathcal{K}$. The action on objects carries an element $b: 1 \to B$ to $\infty$-category $E_b$ defined as the fiber of $p$ over $b$. Similarly, cocartesian fibrations correspond to covariant homotopy coherent diagrams indexed by the underlying quasi-category of the base $\infty$-category and valued in the quasi-category of $(\infty,1)$-categories in $\mathcal{K}$.

Of course, a homotopy coherent diagram indexed by $B^{\text{op}}_0$ could equally be regarded as a contravariant diagram indexed by the underlying quasi-category of $B$ or as a covariant diagram indexed by the opposite of the underlying quasi-category of $B$. However, as observed by Barwick, Glasman, and Nardin in [5], extending a classical observation of Bénabou, the homotopy coherent diagram encoded by the cocartesian fibration $p: E^{\text{op}} \to B^{\text{op}}$ is not the same as the homotopy coherent diagram encoded by the cartesian fibration $p: E \to B$. Rather, the former is defined by postcomposing the latter with the simplicial functor $(-)^{\text{op}}: \text{QC} \to \text{QC}^{\text{op}}$.

We now turn our attention to the construction of the Kan complex core of a quasi-category and discuss its analogue in other $\infty$-cosmoi of $(\infty,1)$-categories.

12.1.9. Definition. For a quasi-category $A$, its groupoid core is the largest sub Kan complex $\text{core}(A) \subset A$, which may be constructed as the simplicial subset containing

- all of the vertices of $A$,
- only those edges that define isomorphisms in $A$, in the sense of Definition 1.1.13,
- every higher simplex whose edges are all isomorphisms.

12.1.10. Lemma. The simplicial set defined in the manner described in Definition 12.1.9 is a Kan complex, and indeed is the largest Kan complex contained in the quasi-category $A$.

²Or, more accurately, with the $(\infty,1)$-categorical core, to be introduced momentarily, of this quasi-categorically enriched functor.
Proof. The inclusion \( \text{core}(A) \subset A \) constructed in Definition 12.1.9 is full on simplices of all dimensions except dimension one. Thus, to see that \( \text{core}(A) \) is a quasi-category, we need only argue that it admits extensions along the horn \( \Lambda^1[2] \hookrightarrow \Delta[2] \). By construction, a horn \( \Lambda^1[2] \rightarrow \text{core}(A) \) picks out two isomorphisms in \( A \). The filler \( \Delta[2] \rightarrow A \) witnesses a composition relation in the homotopy category \( h(A) \); thus the composite edge is also an isomorphism, and by fullness this filler lifts to \( \Delta[2] \rightarrow \text{core}(A) \).

By construction \( h(\text{core}(A)) \) is a groupoid; indeed, it is the maximal subgroupoid contained in \( hA \). So by Corollary 1.1.15, \( \text{core}(A) \) is a Kan complex.

Finally, an intermediate simplicial subset \( \text{core}(A) \subset K \subset A \) would necessarily contain an additional edge \( f : x \rightarrow y \). If \( K \) were a Kan complex, then it would have to admit fillers for \( \Lambda^0[2] \)- and \( \Lambda^2[2] \)-horns whose 2nd or 0th faces, respectively, were the 1-simplex \( f \), and whose remaining face is degenerate. The fillers would construct left and right inverses to \( f \) in \( hA \). Hence, \( f \) is an isomorphism in \( A \) and already lives in \( \text{core}(A) \). \( \square \)

The inclusion defines a cosmological embedding \( \text{Kan} \hookrightarrow \text{QC} \) by Proposition 6.1.6. Functors of quasi-categories preserve isomorphisms, so a functor \( f : A \rightarrow B \) restricts to a functor \( f : \text{core}(A) \rightarrow \text{core}(B) \). In this way the groupoid core construction acts functorially on the underlying category of \( \text{QC} \) and, as an unenriched functor, is right adjoint to the inclusion \( \text{Kan} \hookrightarrow \text{QC} \). Note, however, as discussed in Example 1.3.5, that the core construction is not simplicial, at least not with respect to the usual quasi-categorical enrichment of \( \text{QC} \). Indeed, a natural transformation between functors of quasi-categories will only restrict to groupoid cores if each of its components is invertible.

The groupoid core does, however, define a simplicial functor with respect to a new enrichment that we now introduce. An \( \infty \)-cosmos is a type of \((\infty, 2)\)-category since it is a category enriched over a model of \((\infty, 1)\)-categories. We now introduce the \((\infty, 1)\)-categorical core of an \( \infty \)-cosmos. In the following definition, note that since \( \text{core}(\cdot) : \text{QC} \rightarrow \text{Kan} \) is an (unenriched) right adjoint, it preserves products so we may apply it to the functor spaces of a quasi-categorically enriched category to construct a Kan complex enriched subcategory that we now introduce:

12.1.11. Definition ((\(\infty, 1\))-core of an \(\infty\)-cosmos). For any \(\infty\)-cosmos \( \mathcal{K} \), write \( \text{core}_\ast \mathcal{K} \subset \mathcal{K} \) for the subcategory with the same objects and with homs defined to be the groupoid cores of the functor spaces of \( \mathcal{K} \). We refer to \( \text{core}_\ast \mathcal{K} \) as the \((\infty, 1)\)-core of \( \mathcal{K} \) and think of it as being the core \((\infty, 1)\)-category inside this \((\infty, 2)\)-category.

12.1.12. Remark. The \((\infty, 1)\)-categorical core is not an \(\infty\)-cosmos in the strict sense that we’ve axiomatized in Definition 1.2.1. It inherits its class of isofibrations and the conical limits from the original \(\infty\)-cosmos, but simplicial cotensors exist only weakly: the cotensor of an \(\infty\)-category \( A \) in \( \text{core}_\ast \mathcal{K} \) by a simplicial set \( U \) is constructed by the cotensor in \( \mathcal{K} \) of \( A \) by a Kan complex replacement \( \tilde{U} \) of \( U \), defined by “freely inverting” its edges and adding fillers for horns. This results in an equivalence \( \text{core}(\text{Fun}(X, A))^U \approx \text{core}(\text{Fun}(X, A^{\tilde{U}})) \) in place of the usual isomorphism. Alternatively, Exercise 12.1.iii suggests an alternate approach to defining the enrichment of an \(\infty\)-cosmos in such a way that the \((\infty, 1)\)-core remains an \(\infty\)-cosmos.

12.1.13. Lemma. The natural inclusion \( \text{Kan} \hookrightarrow \text{QC} \) factors through the inclusion \( \text{core}_\ast \text{QC} \subset \text{QC} \) and this latter functor admits a simplicially enriched right adjoint left inverse, namely the functor that sends
each quasi-category to its groupoid core.

\[
\begin{array}{ccc}
\text{Kan} & \perp & \text{core, QCat} \\
\downarrow & & \downarrow \\
\text{core} & \leftarrow & \\
\end{array}
\]

**Proof.** If \(K\) and \(L\) are Kan complexes, then so is \(\text{Fun}(K, L)\). Hence the natural inclusion \(\text{Kan} \hookrightarrow \text{QCat}\) factors through the \((\infty, 1)\)-categorical core.

The right adjoint \(\text{core} : \text{core, QCat} \rightarrow \text{QCat}\) acts on objects by the construction of Definition 12.1.9. To define its action on functor spaces, we must supply a canonical map

\[
\text{core}(\text{Fun}(A, B)) \rightarrow \text{Fun}(\text{core}(A), \text{core}(B)),
\]

for any pair of quasi-categories \(A\) and \(B\). By Corollary D.4.18, the isomorphisms in \(\text{Fun}(A, B)\) are simplicial maps \(\alpha : A \times \Delta[1] \rightarrow B\) whose components \(\alpha_a : \Delta[1] \rightarrow B\), indexed by vertices \(a\) of \(A\), define isomorphisms in \(B\). Combining this observation with Definition 12.1.9, we see that an \(n\)-simplex in \(\text{core}(\text{Fun}(A, B))\) is a simplicial map \(\phi : A \times \Delta[n] \rightarrow B\) with the property that upon restriction to any vertex of \(A\) and any edge of \(\Delta[n]\), the resulting edge in \(B\) is an isomorphism. When \(A\) is restricted to its Kan complex core, the edges of \(\text{core}(A)\) are also isomorphisms. It follows that \(\phi : \text{core}(A) \times \Delta[n] \rightarrow \text{core}(B)\) carries every edge of the domain to an isomorphism in \(B\), and hence factors through \(\text{core}(B) \hookrightarrow B\), since this inclusion is full on the invertible edges.\(^1\) Thus the \(n\)-simplex \(\phi\) restricts to define an \(n\)-simplex \(\phi : \text{core}(A) \times \Delta[n] \rightarrow \text{core}(B)\). This defines the canonical map.

Now for a Kan complex \(K\) and quasi-category \(A\), the simplicial natural isomorphism

\[
\text{core}(\text{Fun}(K, A)) \cong \text{Fun}(K, \text{core}(A))
\]

is easily verified. The correspondence on vertices expresses the unenriched adjunction, while the correspondence on higher simplices follows for the reason just discussed and the isomorphism \(\text{core}(K) \cong K\).

12.1.14. **Corollary.** If \(A\) and \(B\) are equivalent quasi-categories, then \(\text{core}(A)\) and \(\text{core}(B)\) are equivalent Kan complexes.

**Proof.** An equivalence of quasi-categories is specified by a pair of 0-arrows together a pair of invertible 1-arrows. As such it is contained in the \((\infty, 1)\)-categorical core \(\text{core, QCat} \hookrightarrow \text{QCat}\) and preserved by the simplicial functor \(\text{core} : \text{core, QCat} \rightarrow \text{Kan}\).

The core of an \(\infty\)-category in a general \(\infty\)-cosmos of \((\infty, 1)\)-categories can be defined in a similar manner to Definition 12.1.4, but this notion also has an up-to-equivalence universal property that we prefer to use as the definition.

12.1.15. **Definition.** Let \(\mathcal{K}\) be an \(\infty\)-cosmos of \((\infty, 1)\)-categories and let \(A\) be an \(\infty\)-category in \(\mathcal{K}\). Its \(\infty\)-groupoid core is an \(\infty\)-category \(\text{core}(A)\) equipped with a map \(\iota : \text{core}(A) \rightarrow A\) so that

- \(\text{core}(A)\) is a discrete \(\infty\)-category, meaning that \(\text{Fun}(X, A)\) is a Kan complex for all \(X\)
- if \(G\) is a discrete \(\infty\)-category, then \(\iota\) defines an equivalence

\[
\text{Fun}(G, \text{core}(A)) \xrightarrow{\iota_*} \text{core}(\text{Fun}(G, A))
\]

\(^1\)In the language of marked simplicial sets, a map in \(\text{core}(\text{Fun}(A, B))\) is a marked map \(A^\sharp \times \Delta[n]^\sharp \rightarrow B^\sharp\). Upon restriction along \(\text{core}(A)^\sharp \hookrightarrow A^\sharp\), the domain \(\text{core}(A)^\sharp \times \Delta[n]^\sharp\) is maximally marked, and hence factors through the maximally marked core \(\text{core}(B)^\sharp \hookrightarrow B^\sharp\). See §D.4.
In practice, an $\infty$-cosmos of $(\infty,1)$-categories frequently comes with an explicit core functor, but as in the case of opposites, one can also be defined by transferring the core construction along a suitable change-of-model functor:

12.1.16. **Proposition.** Let $\mathcal{K}$ be an $\infty$-cosmos of $(\infty,1)$-categories.

(i) Any $\infty$-category in $\mathcal{K}$ has a core, well-defined up to equivalence.

(ii) Any specified choices in (i) assemble into a quasi-pseudofunctor $\text{core}: \text{core}_* \mathcal{K} \to \text{Disc}(\mathcal{K})$ defined as the composite of the zig-zag of Kan complex enriched functors

\[
\begin{align*}
\text{core}_* \mathcal{K} & \xrightarrow{(-)_0} \text{core}_* \mathcal{QCat} \\
\text{Disc}(\mathcal{K}) & \xrightarrow{(-)_0} \text{Disc}(\mathcal{QCat}) \cong \text{Kan}
\end{align*}
\]

(iii) In particular, for any $\infty$-categories $A, B \in \mathcal{K}$, there is a map

\[
\text{core}(\text{Fun}(A, B)) \to \text{Fun}(\text{core}(A), \text{core}(B))
\]

that is quasi-pseudonatural in $A$ and in $B$ as objects of $\text{core}_* \mathcal{K}$.

Implicitly in the statement of (ii) we have asserted that a cosmological biequivalence $\mathcal{K} \xrightarrow{\sim} \mathcal{L}$ descends to a cosmological biequivalence $\text{Disc}(\mathcal{K}) \xrightarrow{\sim} \text{Disc}(\mathcal{L})$ and a simplicially enriched biequivalence $\text{core}_* \mathcal{K} \xrightarrow{\sim} \text{core}_* \mathcal{L}$. The first statement is proven in Corollary 10.3.7 while the second follows from Corollary 12.1.14 and is left to Exercise 12.1.iv.

**Proof.** By Proposition 10.4.16 the inverse to the cosmological biequivalence $(-)_0: \text{Disc}(\mathcal{K}) \xrightarrow{\sim} \text{Kan}$, defines a quasi-pseudofunctor and biequivalence $\text{Kan} \xrightarrow{\sim} \text{Disc}(\mathcal{K})$, which composes with the simplicial functor $\text{core}(-)_0: \text{core}_* \mathcal{K} \to \text{Kan}$ to define the quasi-pseudofunctor $\text{core}: \text{core}_* \mathcal{K} \to \text{Disc}(\mathcal{K})$ claimed in (ii).

By Lemma 10.4.12, the action on homs of this quasi-pseudofunctor defines a quasi-pseudonatural transformation

\[
\text{core}(\text{Fun}(A, B)) \to \text{Fun}(\text{core}(A), \text{core}(B)),
\]

as required in (iii).

It remains only to verify that the action on objects of the quasi-pseudofunctor satisfies the conditions of Definition (12.1.15). By construction, core$(A)$ is a discrete $\infty$-category for any $A \in \mathcal{K}$. The map $t: \text{core}(A) \to A$ is defined by whiskering the corresponding inclusion of the Kan complex core of quasi-category with the underlying quasi-category functor and its quasi pseudofunctorial inverse:

\[
\begin{align*}
\text{core}_* \mathcal{K} & \xrightarrow{(-)_0} \text{core}_* \mathcal{QCat} \\
\text{Disc}(\mathcal{K}) & \xrightarrow{(-)_0} \text{Disc}(\mathcal{QCat}) \cong \text{Kan}
\end{align*}
\]

Now if $G$ is a discrete $\infty$-category, then $G_0 = \text{Fun}(1, G)$ is a Kan complex, so by Lemma 12.1.13 $t_A \circ -: \text{Fun}(G_0, \text{core}(A)) \xrightarrow{\sim} \text{coreFun}(G_0, \text{core}(A))$ is an equivalence. By construction core$(A)$ is defined so that core$(A)_0 \simeq \text{core}(A_0)$. Note that since $(-)_0: \mathcal{K} \xrightarrow{\sim} \mathcal{QCat}$ is a biequivalence, this shows that the core of an $\infty$-category in an $\infty$-cosmos of $(\infty,1)$-categories is well-defined up to equivalence.
Since the simplicial functor \((-)_0: \text{core}_\mathcal{K} \to \text{core}_\mathcal{QCat}\) is an equivalence on homs, the functor defined by post-composition with \(\iota_A\) is equivalent to this functor

\[
\begin{array}{ccc}
\text{Fun}(G, \text{core}(A)) & \xrightarrow{\iota_A^\circ} & \text{coreFun}(G, A) \\
\downarrow (-)_0 & \cong & \downarrow (-)_0 \\
\text{Fun}(G_0, \text{core}(A_0)) & \xrightarrow{\iota_{A_0}^\circ} & \text{coreFun}(G_0, A_0)
\end{array}
\]

Thus post-composition with \(\iota_A\) induces the equivalence \(\text{Fun}(G, \text{core}(A)) \simeq \text{coreFun}(G, A)\) required by Definition (12.1.15). This completes the proof of (i).

\[\square\]

**Exercises.**

12.1.i. **Exercise.** Prove that the homotopy category of the opposite of an \(\infty\)-category \(A\) is equivalent to the opposite of the homotopy category of \(A\).

12.1.ii. **Exercise.** Prove that a functor between \(\infty\)-categories is an equivalence if and only if its opposite functor is an equivalence.

12.1.iii. **Exercise.** In consultation with §D.4 and §D.5:

(i) Redefine the notion of an \(\infty\)-cosmos from Definition 1.2.1 to be a category enriched over marked simplicial sets, whose functor spaces are naturally marked quasi-categories.

(ii) Describe the construction of the groupoid core of a naturally marked quasi-category and of the \((\infty, 1)\)-categorical core of an \(\infty\)-cosmos with this enrichment.

(iii) Show that \((\infty, 1)\)-categorical cores are cotensored over simplicial sets, although these cotensors are not preserved by the inclusion \(\text{core}_\mathcal{K} \hookrightarrow \mathcal{K}\).

(iv) Show that the \((\infty, 1)\)-categorical core of an \(\infty\)-cosmos is an \(\infty\)-cosmos in the new sense, although the functor \(\text{core}_\mathcal{K} \hookrightarrow \mathcal{K}\) is still not cosmological.

12.1.iv. **Exercise.** Let \(F: \mathcal{K} \to \mathcal{L}\) be a cosmological functor. Prove that \(F\) induces a simplicial functor \(F: \text{core}_\mathcal{K} \to \text{core}_\mathcal{L}\) that is a biequivalence if the original functor is.

12.1.v. **Exercise.**

(i) Prove that any adjunction between quasi-categories

\[
\begin{array}{ccc}
B & \xleftarrow{f} & A \\
\downarrow \iota & & \downarrow \iota \\
& A & B
\end{array}
\]

restricts to define an adjoint equivalence between the full sub quasi-categories spanned by those elements \(b: 1 \to B\) and \(a: 1 \to A\) for which the unit and counit components, respectively, are invertible.

(ii) State and prove an analogous result about adjoint equivalences derived from adjunctions in an arbitrary \(\infty\)-cosmos of \((\infty, 1)\)-categories.

**12.2. Pointwise Universal Properties**

In \(\infty\)-cosmoi of \((\infty, 1)\)-categories, the terminal \(\infty\)-category \(1\) plays a special role which can be summarized by the slogan that “universal properties are detected pointwise.” In this section, we collect together a number of results that encapsulate this slogan, which are proven through a combination of synthetic and analytic techniques.
For instance, Corollary D.4.18 proves that a natural transformation between functors between quasi-categories $X \xrightleftharpoons[\alpha]{g} A$ is a natural isomorphism if and only if it is a pointwise isomorphism, meaning that each of its components

$$1 \xrightarrow{x} X \xrightleftharpoons[\alpha]{g} A$$

is invertible. Consequently:

12.2.1. **Lemma.** In an $\infty$-cosmos of $(\infty,1)$-categories, a natural transformation is a natural isomorphism if and only if it is a pointwise isomorphism.

Put another way, a natural transformation $X \xrightleftharpoons[\alpha]{g} A$ between functors between $(\infty,1)$-categories is an isomorphism if and only if each of its components $\alpha x$ defines an isomorphism in the homotopy category of $A$; see Definition 1.4.12.

**Proof.** It’s clear that any natural isomorphism is a pointwise isomorphism. For the converse, we use the 2-categorical biequivalence $(-)_0 : \mathcal{K} \simeq \mathcal{QCat}$ of Propositions 10.2.2 and 10.3.1. Suppose $X \xrightleftharpoons[\alpha]{g} A$ is a pointwise natural isomorphism in $\mathcal{K}$ and consider the underlying natural transformation between underlying quasi-categories $X_0 \xrightleftharpoons[\alpha_0]{g_0} A_0$. By construction, vertices of $X_0 \equiv \text{Fun}(1,X)$ correspond bijectively to elements of $X$, so the underlying natural transformation $\alpha_0$ is a pointwise natural isomorphism in $\mathcal{QCat}$ as well. Thus, Corollary D.4.18 applies to prove that $\alpha_0$ admits an inverse $X_0 \xrightleftharpoons[\alpha_0^{-1}]{g_0} A_0$. By the full and faithfulness of the local equivalence $\text{hFun}(X,A) \simeq \text{hFun}(X_0,A_0)$ established in Proposition 10.3.1, this 2-cell lifts to define an inverse natural transformation $X \xrightleftharpoons[\alpha^{-1}]{g} A$ witnessing the invertibility of $\alpha$. □

We took advantage of a special feature of the cosmological biequivalence $(-)_0 : \mathcal{K} \simeq \mathcal{QCat}$ to simplify the proof of Lemma 12.2.1 that is worth calling attention to.

12.2.2. **Observation (on the elements of the underlying quasi-category).** By Corollary 10.3.2(ii), a cosmological biequivalence $F : \mathcal{K} \simeq \mathcal{L}$ induces a bijection between isomorphism classes of elements of an $\infty$-category $A \in \mathcal{K}$ and isomorphism classes of elements of $FA \in \mathcal{L}$, and in fact induces an equivalence of homotopy categories $\text{hA} \simeq \text{hFA}$, the objects of which are exactly these elements; see Exercise 10.3.i. In particular, any element $x : 1 \to FA$ is naturally isomorphic to an element
Fa: $1 \to FA$ that is the image of an element $a: 1 \to A$. Since “pointwise” $\infty$-categorical notions — invertibility of the components of a natural isomorphism, possession of a terminal element in the fibers of a cocartesian fibration — are invariant under isomorphism, if $A$ satisfies some pointwise criterion in $\mathcal{K}$, then $FA$ will satisfy the corresponding pointwise criterion in $\mathcal{L}$.

But in the case of $\infty$-cosmoi of $(\infty, 1)$-categories, Proposition 10.2.2 supplies a cosmological biequivalence $(-)_0: \mathcal{K} \to QCat$ that acts bijectively on elements of $\infty$-categories. By construction, vertices of $A_0 \cong \text{Fun}(1, A)$ correspond bijectively to elements of $A$. Thus, every element of the underlying quasi-category $A_0$ of an $\infty$-category $A$ comes from some element of $A$. Consequently, as we saw in the proof of Lemma 12.2.1, “pointwise” properties may be transferred even more readily.

Using Lemma 12.2.1, we can show that an isofibration in an $\infty$-cosmos of $(\infty, 1)$-categories is a discrete object of the slice $\infty$-cosmos if and only if its fibers are discrete $\infty$-categories. It follows that cocartesian, cartesian, or two-sided fibrations of $(\infty, 1)$-categories are discrete if and only if they have discrete fibers.

12.2.3. PROPOSITION. Let $p: E \to B$ be an isofibration in an $\infty$-cosmos $\mathcal{K}$ of $(\infty, 1)$-categories. Then $p$ is discrete as an object of $\mathcal{K}/B$ if and only if the fibers of $p$ are discrete $\infty$-categories.

PROOF. Any element $b: 1 \to B$ induces a cosmological functor $b^*: \mathcal{K}/B \to \mathcal{K}$ which preserves discrete $\infty$-categories by Proposition 10.1.7. So for any $\infty$-cosmos $\mathcal{K}$, if $p: E \to B$ is a discrete object in $\mathcal{K}/B$, then its fibers are discrete $\infty$-categories.

For the converse we assume that $\mathcal{K}$ is an $\infty$-cosmos of $(\infty, 1)$-categories and appeal to Lemma 12.2.1. To show that $p: E \to B$ is discrete in $\mathcal{K}/B$ we must argue that the quasi-category defined by the pullback

$$
\begin{array}{ccc}
\text{Fun}_B(f: X \to B, p: E \to B) & \longrightarrow & \text{Fun}(X, E) \\
\downarrow & \searrow \downarrow p_* & \downarrow p_* \\
1 & \longrightarrow & \text{Fun}(X, B)
\end{array}
$$

is a Kan complex. By Corollary 1.1.15, it suffices to show that its homotopy category is a groupoid. To that end, consider a 1-simplex $\alpha: e \to e'$ in $\text{Fun}_B(f, p) \hookrightarrow \text{Fun}(X, E)$, representing a natural transformation $X \xleftarrow{\llcorner \alpha} E$ in the homotopy 2-category. The 1-simplex $\alpha$ has the property that the whiskered composite $p\alpha \in \text{Fun}(X, B)$ is the degenerate 1-simplex at $f$. This implies, but is stronger than, the property that the whiskered composite in the homotopy 2-category equals the 2-cell $\text{id}_f$; see §3.6 for a discussion. □
Our next series of results will show that universal properties can be detected pointwise in ∞-cosmoi of \((\infty, 2)\)-categories. The key technical ingredient is an analytical result about quasi-categories in the style of Joyal and Lurie.

12.2.4. Proposition. A cocartesian fibration \(q: E \to A\) of quasi-categories admits a right adjoint right inverse \(t: A \to E\) if and only if for each \(a: 1 \to A\) the fiber \(E_a\) has a terminal element.

Proof. By Corollary 3.6.9, a right adjoint right inverse to \(q\) can be interpreted as defining a terminal element in \(q: E \to A\), considered as an object in the sliced ∞-cosmos \(QC\)\(\text{at}_A\). By Lemma 3.6.6(i), this fibered adjunction may be pulled back along any element \(a: 1 \to A\) to define a terminal element in the fiber \(E_a\).

For the converse, let \(ta: 1 \to E_a\) denote a chosen terminal element in the fiber \(E_a\) over \(a: 1 \to A\). Lemma F.3.1 characterizes those isofibrations between quasi-categories that admit a right adjoint right inverse in terms of a lifting property. In this case, it suffices to show that any lifting problem

\[
\begin{array}{ccc}
1 & \xrightarrow{[n]} & \partial \Delta[n] \\
| & | & | \downarrow q \\
\Delta[n] & \xrightarrow{x} & A \\
& | & \\
& \Delta[n] \times \Delta[1] & \xrightarrow{xk} & A
\end{array}
\]

for \(n \geq 1\) has a solution. To that end, consider the simplicial map \(k: \Delta[n] \times \Delta[1] \to \Delta[n]\) defined on vertices by \(k(i, 0) \coloneqq i\) and \(k(i, 1) \coloneqq n\). The composite \(\chi k: \Delta[n] \times \Delta[1] \to A\) restricts to define a map \(\chi k: \partial \Delta[n] \times \Delta[1] \to A\) which represents a 2-cell whose codomain, defined by evaluating at the vertex \(1\) of \(\Delta[1]\), is constant at \(a\) and whose domain factors through \(q\) along \(y\). This yields a new lifting problem

\[
\begin{array}{ccc}
\partial \Delta[n] & \xrightarrow{y} & E \\
\downarrow i_0 & & \downarrow q \\
\Delta[n] \times \Delta[1] & \xrightarrow{xk} & A \\
\end{array}
\]

which Lemma F.4.9 enables us to solve. By Lemma F.4.9, the lift \(z\) represents a \(q\)-cocartesian lift \(\zeta\) of the 2-cell \(\kappa\) represented by the restriction of \(\chi k\):

\[
\begin{array}{ccc}
\partial \Delta[n] & \xrightarrow{y} & E \\
\downarrow & & \downarrow q \\
1 & \xrightarrow{a} & A \\
\end{array}
\]

By construction, the codomain functor of the \(q\)-cocartesian lift displayed above right lands in the fiber over \(a\). Now the component of \(\kappa\) at the final vertex \(\{n\}: 1 \to \partial \Delta[n]\) is \(\id_a\), so by Lemma 5.1.9(ii), the component \(z\{n\}\) representing the 2-cell \(\zeta\{n\}\) is an isomorphism. In particular, the element \(u\{n\}: 1 \to E\) is isomorphic to the terminal element \(y\{n\} = ta\) of \(E_a\), so we may apply the universal property of
Proposition F.1.1(vi) to extend \( u \) to a simplex:

\[
\partial \Delta[n] \xrightarrow{u} E \atop \Downarrow \nu \quad \Delta[n]
\]

This data defines a new lifting problem

\[
\begin{array}{c}
\partial \Delta[n] \\
\Downarrow \iota_0 \\
\Delta[n]
\end{array}
\begin{array}{c}
\Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} \\
\Downarrow z \cup y \\
E
\end{array}
\begin{array}{c}
\Downarrow q \\
\Delta[n] \times \Delta[1] \\
\Downarrow x_k \\
A
\end{array}
\]

which we solve inductively by choosing lifts of the \( n+1 \) \((n+1)\)-simplices in \( \Delta[n] \times \Delta[1] \) not present in \( \partial \Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} \), starting from the \( n+1 \)-simplex that contains the face \( \Delta[n] \times \{1\} \). All but the last of these can be lifted by means of lifting inner horns against the isofibration \( q \). For the final simplex, we must solve an outer horn lifting problem

\[
\begin{array}{c}
\Delta[1] \\
\Downarrow z[n] \\
\Lambda^{n+1}[n+1] \\
\Downarrow q \\
\Delta[n+1] \rightarrow A
\end{array}
\]

but in this case the final edge of the outer horn is the isomorphism \( z[n] \), so Proposition 1.1.14 permits its solution as well. Now the lift (12.2.5) restricts to define the sought-for solution to the original lifting problem, proving that \( q : E \rightarrow A \) admits a right adjoint right inverse. \( \square \)

Via the cosmological isomorphism \((-)_{\text{op}} : \mathcal{Q}Cat \rightarrow \mathcal{Q}Cat_{\text{co}} \) of Lemma 12.1.3, the proof of Proposition 12.2.4 dualizes to prove that a cartesian fibration of quasi-categories admits a left adjoint right inverse if and only if each fiber has an initial element. See Exercise 12.2.i.

The proof of Proposition 12.2.4 relied heavily on “analytic” techniques. Nonetheless its conclusion transfers to any \( \infty \)-cosmos that is biequivalent to the \( \infty \)-cosmos of quasi-categories.

12.2.6. PROPOSITION. In an \( \infty \)-cosmos of \((\infty, 1)\)-categories a cocartesian fibration \( q : E \rightarrow A \) of admits a right adjoint right inverse \( t : A \rightarrow E \) if and only if for each \( a : 1 \rightarrow A \) the fiber \( E_a \) has a terminal element.

PROOF. The argument that the fibers of an isofibration with right adjoint right inverse admit terminal elements is the same as given in the proof of Proposition 12.2.4. For the converse, suppose \( q : E \rightarrow A \) is a cocartesian fibration in an \( \infty \)-cosmos \( \mathcal{K} \) that is biequivalent to \( \mathcal{Q}Cat \) with the property that for each element \( \alpha : 1 \rightarrow A \) of the base, the fiber \( E_a \) has a terminal element. By Proposition 10.2.2, we may use the biequivalence underlying quasi-category functor \((-)_{\text{0}} : \mathcal{K} \Rightarrow \mathcal{Q}Cat \) to conclude that \( q \) admits a right adjoint right inverse.
Cosmological functors preserve cocartesian fibrations, so the underlying map \( q_0 : E_0 \to A_0 \) defines a cocartesian fibration of quasi-categories. By Observation 12.2.2, elements of the underlying quasi-category \( A_0 \) correspond bijectively to elements of the \( \infty \)-category \( A \). By hypothesis, for every \( a : 1 \to A \) the \( \infty \)-category \( E_a \) admits a terminal element, so by Proposition 10.1.7 the underlying quasi-category \( (E_a)_0 \) does as well. In this way, we see that every fiber of the cocartesian fibration of quasi-categories \( q_0 : E_0 \to A_0 \) admits a terminal element. By Proposition 12.2.4, \( q_0 \) admits a right adjoint right inverse. Now by Proposition 10.3.6(ii), we may conclude that \( q : E \to A \) admits a right adjoint right inverse in \( \mathcal{K} \), as desired. \( \square \)

An important special case of Proposition 12.2.6 proves a result promised in the discussion surrounding Proposition 4.1.6: in an \( \infty \)-cosmos of \( (\infty, 1) \)-categories a functor \( f : B \to A \) admits a right adjoint just when for each element \( a : 1 \to A \), the \( \infty \)-category \( \text{Hom}_A(f, a) \) admits a terminal element: namely the counit component "\( ea " : 1 \to \text{Hom}_A(f, a) " \). In the terminology used by Mac Lane [79, §III.1], this universal property exhibits "\( ea " \) as a “universal arrow” from the functor \( f \) to the element \( a \).

**12.2.7. COROLLARY.** In an \( \infty \)-cosmos of \( (\infty, 1) \)-categories, a functor \( f : B \to A \) admits a right adjoint if and only if for each element \( a : 1 \to A \), the comma \( \infty \)-category \( \text{Hom}_A(f, a) \) admits a terminal element.

The dual result follows from the dual of Proposition 12.2.6, whose proof is discussed in Exercises 12.2.i and 12.2.ii.

**Proof.** Proposition 4.1.6 demonstrates that in any \( \infty \)-cosmos, \( f : B \to A \) admits a right adjoint if and only if \( \text{Hom}_A(f, A) \) “admits a terminal element over \( A \),” meaning that \( p_1 : \text{Hom}_A(f, A) \to A \) admits a right adjoint right inverse. By Corollary 5.6.16, this functor is a cocartesian fibration, so Proposition 12.2.6 tells us that \( p_1 \) admits a right adjoint right inverse if and only if each fiber \( \text{Hom}_A(f, a) \) admits a terminal element. \( \square \)

Proposition 12.2.6 implies that modules between \( (\infty, 1) \)-categories admit an analogous “pointwise” representability condition, characterizing those modules that are covariantly or contravariantly represented by a functor in the sense of Definition 7.4.8.

**12.2.8. COROLLARY.** In an \( \infty \)-cosmos of \( (\infty, 1) \)-categories, a module \( A \xleftarrow{E} B \) is covariantly represented if and only if for each \( a : 1 \to A \), the module \( \xleftarrow{E(1,a)} B \) is covariantly represented by some element \( b : 1 \to B \), which is the case if and only if each \( \infty \)-category \( E_a \) admits a terminal element.

**Proof.** By Proposition 8.4.10, a module \( A \xleftarrow{E} B \) encoded by a span \( (q, p) : E \to A \times B \) is covariantly represented if and only if its left leg \( q : E \to A \) admits a right adjoint right inverse \( r : A \to E \), in which case \( E \cong \text{Hom}_B(B, pr) \). By Lemma 7.4.3, the left left \( q : E \to A \) defines a cocartesian fibration, so by Proposition 12.2.6, \( q \) admits a right adjoint right inverse if and only if the fiber \( E_a \) over each element \( a : 1 \to A \) admits a terminal element. For each \( a : 1 \to A \), the module \( \xleftarrow{E(1,a)} B \) is given by the pullback along \( a \times \text{id} : 1 \times B \to A \times B \) and hence is isomorphic to the module \( \xleftarrow{E_a} B \). Applying Proposition 8.4.10 again, this module is covariantly represented by some element \( b : 1 \to B \) if and only if \( E_a \cong \xleftarrow{E(1,a)} B \) admits a right adjoint right inverse, which is the case if and only if this \( \infty \)-category admits a terminal element. \( \square \)

Our next result concerns absolute lifting diagrams, used in Definition 2.3.7 to define the limit and colimit of a family of diagrams. There is a certain elegance in considering families of diagrams,
rather than individual diagrams, when it comes to stating results such as Proposition 2.3.13, but it is also useful to establish the existence of limits and colimits one diagram at a time. In ∞-cosmoi of (∞,1)-categories, this sort of reduction is possible, on account of the following:

12.2.9. **Proposition.** In any ∞-cosmos of (∞,1)-categories:

(i) A functor \( g : C \to A \) admits an absolute right lifting through a functor \( f : B \to A \) if and only if for all \( c : 1 \to C \), the comma ∞-category \( \text{Hom}_A(f, gc) \) admits a terminal element.

(ii) A triangle as below-left

\[
\begin{array}{ccc}
B & \xrightarrow{f} & A \\
\downarrow r & & \downarrow f \\
C & \xrightarrow{g} & A \\
\end{array}
\]

displays \( r \) as an absolute right lifting of \( g \) through \( f \) if and only if for all \( c : 1 \to C \), the restricted triangle as above-right displays \( rc \) as an absolute right lifting of \( gc \) through \( f \).

(iii) A functor \( g : C \to A \) admits an absolute right lifting through a functor \( f : B \to A \) if and only if for all \( c : 1 \to C \) there exists an absolute right lifting of \( gc \) through \( f \) as below-left

\[
\begin{array}{ccc}
B & \xrightarrow{f} & A \\
\downarrow r_c & & \downarrow f \\
1 & \xrightarrow{g_c} & A \\
\end{array}
\]

in which case the components of the absolute right lifting of \( g \) through \( f \) are isomorphic to the corresponding pointwise absolute liftings: \( r_c \cong rc \) and \( \rho_c \cong \rho c \).

**Proof.** Theorems 3.5.8 and 3.5.12 demonstrate that in any ∞-cosmos, a functor \( g : C \to A \) admits a right lifting through \( f : B \to A \) if and only if the codomain-projection functor \( p_1 : \text{Hom}_A(f, g) \to C \) admits a right adjoint right inverse. By Corollary 5.6.16 this functor is a cocartesian fibration. Now Proposition 12.2.6 proves that in an ∞-cosmos of (∞,1)-categories, \( p_1 : \text{Hom}_A(f, g) \to C \) admits a right adjoint right inverse if and only if each fiber \( \text{Hom}_A(f, gc) \) over an element \( c : 1 \to C \) admits a terminal element. This proves the first statement.

Since absolute lifting diagrams are stable under restriction, it is immediately clear that any absolute right lifting diagram as above-left, restricts to define a pointwise absolute right lifting diagram as above-right. For the converse, suppose \( (rc, \rho c) \) defines an absolute right lifting of \( gc \) through \( f \) for any \( c : 1 \to C \). By Theorem 3.5.12, it follows that each comma ∞-category \( \text{Hom}_A(f, gc) \) has a terminal element and so by (i), \( g : C \to A \) must admit an absolute right lifting \( (s, \sigma) \) through \( f : B \to A \). By its universal property, the pair \( (r, \rho) \) factors through \( (s, \sigma) \) via a 2-cell \( \tau : r \Rightarrow s \) so that \( \rho = \sigma \circ f \tau \). Since \( (rc, \rho c) \) and \( (sc, \sigma c) \) are both absolute right lifting diagrams, we know that each component \( \tau c \) is an isomorphism. Hence, by Lemma 12.2.1, \( \tau \) is an isomorphism, and thus \( (r, \rho) \) is also an absolute right lifting diagram, as desired.

The third statement is a convenient summary of the first two. If \( gc \) admits an absolute right lifting through \( f \) then \( \text{Hom}_A(f, gc) \) has a terminal element and (i) guarantees the existence of an absolute right lifting of \( g \) through \( f \). The component of \( (r, \rho) \) at \( c \) defines a second absolute right lifting of \( gc \) through \( f \) inducing the claimed isomorphisms. \( \Box \)

As a corollary, we may resolve the question raised in Remark 2.3.8.
12.2.10. **Corollary.** In an $\infty$-cosmos of $(\infty, 1)$-categories if $A$ is an $\infty$-category that admits limits of every diagram $d: 1 \to A$ of shape $J$ then $A$ admits all limits of shape $J$: that is, the constant diagram functor admits a right adjoint

$$A \leftarrow \Delta \downarrow \lim \rightarrow A$$

**Proof.** By Proposition 12.2.9(iii), the functor $\text{id}_A: A \to A$ admits an absolute right lifting through $\Delta: A \to A$ if and only if each diagram $d: 1 \to A$ admits an absolute right lifting through $\Delta: A \to A$. By Definition 2.3.7 the latter condition encodes what it means for $A$ to admit a limit of the diagram $d$, while by Lemma 2.3.6 the former condition encodes what it means for $\Delta: A \to A$ to admit a right adjoint. □

Another proof of Proposition 12.2.9(ii) is possible. By Theorem 3.5.8, a 2-cell $\rho: f \Rightarrow g$ defines an absolute right lifting if and only if the induced functor $\langle \rho \rangle: \text{Hom}_B(B, r) \to \text{Hom}_A(f, g)$ is an equivalence over $C \times B$. As we shall now discover, equivalences between co/cartesian fibrations or modules can be detected fiberwise in $\infty$-cosmoi of $(\infty, 1)$-categories. As was our strategy for constructing right adjoint right inverses to cocartesian fibrations, we first prove this result for quasi-categories, using analytic techniques. Alternate analytic proofs can be found in [74, 3.3.1.5] and [3, 2.9]. We then use model-independence to conclude that the same result holds true in arbitrary $\infty$-cosmoi of $(\infty, 1)$-categories.

12.2.11. **Proposition.** A cartesian functor

$$B \quad \begin{array}{c} E \xrightarrow{g} F \xrightarrow{p} B \end{array}$$

between cocartesian fibrations of quasi-categories is a fibered equivalence if and only if it is a fiberwise equivalence, meaning that for each $b: 1 \to B$, the induced functor between fibers $g_b: E_b \to F_b$ is an equivalence.

Note the subtle difference in terminology between “fibered equivalences” — equivalences over $B$ — and “fiberwise equivalences” — maps inducing equivalences on fibers over elements of $B$. This result and Proposition 12.2.12 to follow show that in fact these two notions coincide for $\infty$-cosmoi of $(\infty, 1)$-categories.

**Proof.** Fibered equivalences are stable under pullback to fibers, so the content is in the converse implication: that any cartesian functor between cocartesian fibrations that induces a fiberwise equivalence is necessarily an equivalence.

The cartesian functor $g$ can be factored in the slice $\mathcal{Q} \text{Cat}_{/B}$ as an equivalence followed by an isofibration. By Corollary 5.3.1, the intermediate object of that factorization is again a cocartesian fibration and the isofibration from it to $q: F \Rightarrow B$ is again a cartesian functor. Replacing $p: E \Rightarrow B$ by the equivalent cocartesian fibration, it therefore suffices to assume that $g: E \Rightarrow B$ is an isofibration and a cartesian functor and postulate that each induced map $g_b: E_b \Rightarrow F_b$ is a trivial fibration. Under these assumptions, we must show that $g$ is itself a trivial fibration.
To that end, suppose that we are given a lifting problem

\[
\begin{array}{ccc}
\partial \Delta[n] & \xrightarrow{e} & E \\
\downarrow & & \downarrow g \\
\Delta[n] & \xrightarrow{f} & F
\end{array}
\]

over \(b: \Delta[n] \to B\). Consider the retract diagram

\[
\begin{array}{ccc}
\Delta[n] & \xrightarrow{id \times 0} & \Delta[n] \times \Delta[1] \\
\downarrow i & & \downarrow r \\
(i,0) & & \Delta[n] \\
\end{array}
\]

and choose a pointwise \(p\)-cocartesian lift

\[
\begin{array}{ccc}
\Delta[n] \times \{0\} & \xrightarrow{e} & E \\
\downarrow \chi & & \downarrow p \\
\Delta[n] \times \Delta[1] & \xrightarrow{br} & B
\end{array}
\]

as permitted by Lemma F.4.9. Applying \(g\) we obtain a hollow cylinder

\[
\begin{array}{ccc}
\partial \Delta[n] \times \Delta[1] & \xrightarrow{\chi} & E \\
\downarrow & & \downarrow g \\
\Delta[n] \times \Delta[1] & \xrightarrow{br} & B
\end{array}
\]

and since \(g\) is a cartesian functor and \(\chi\) is pointwise \(p\)-cocartesian it follows that \(g\chi\) is pointwise \(q\)-cocartesian. Now by construction the simplex \(f: \Delta[n] \times \{0\} \to F\) agrees with \(g\chi: \Delta[n] \times \Delta[1] \to F\) on the subset \(\Delta[n] \times \{0\}\) where they are both defined. It follows that they combine to give a well defined simplicial map on the union of their domains and so provide us with a second lifting problem:

\[
\begin{array}{ccc}
\Delta[n] \times \{0\} \cup \partial \Delta[n] \times \Delta[1] & \xrightarrow{f \cup g\chi} & F \\
\downarrow & & \downarrow q \\
\Delta[n] \times \Delta[1] & \xrightarrow{br} & B
\end{array}
\]

which can again be solved to give a pointwise \(q\)-cocartesian lift \(\rho\) by Lemma F.4.9. Note now that the retraction \(r: \Delta[n] \times \Delta[1] \to \Delta[n]\) was constructed to map the subset \(\Delta[n] \times \{1\}\) onto the vertex \(\{n\}\), from which it follows that the \(n\)-simplex

\[
\begin{array}{ccc}
\Delta[n] \times \{0\} \cup \partial \Delta[n] \times \Delta[1] & \xrightarrow{f \cup g\chi} & F \\
\downarrow & & \downarrow q \\
\Delta[n] \times \Delta[1] & \xrightarrow{br} & B
\end{array}
\]

is a degenerate image of the final vertex \(b_n := b \cdot \{n\}\). Now observe that the cylinders \(\chi\) and \(\rho\) were defined to lie over \(br: \Delta[n] \times \Delta[1] \to B\), so it follows that the restricted maps

\[
\begin{array}{ccc}
\Delta[n] \times \{1\} & \xrightarrow{\chi} & E \\
\Delta[n] \times \{1\} & \xrightarrow{\rho} & F
\end{array}
\]
land in the fibers $E_{b_n}$ and $F_{b_n}$ of $p$ and $q$ respectively. Consequently we obtain a lifting problem

\[
\begin{array}{c}
\partial \Delta[n] \\
\downarrow \\
\Delta[n]
\end{array}
\xrightarrow{\chi|_{\{1\}}} 
\begin{array}{c}
E_{b_n} \\
\downarrow g_{b_n}
\end{array}
\xrightarrow{\gamma|_{\{1\}}} 
\begin{array}{c}
F_{b_n}
\end{array}
\]

which we may solve since the map of fibers on the right is, by assumption, a trivial fibration. Now the upper left triangle tells us that $\chi$ and $\gamma$ agree on the subset $\Delta[n] \times \{1\}$ where they are both defined. Thus, these maps combine to give the well defined simplicial map on the union of their domains depicted as the upper-horizontal in the lifting problem on the right of the following diagram:

\[
\begin{array}{c}
\partial \Delta[n] \times \{0\} \\
\downarrow \\
\Delta[n] \times \{0\}
\end{array}
\xrightarrow{\partial \Delta[n] \times \{1\} \cup \partial \Delta[n] \times \Delta[1]} 
\begin{array}{c}
\Delta[n] \times \{1\} \cup \partial \Delta[n] \times \Delta[1] \\
\downarrow \\
\Delta[n] \times \Delta[1]
\end{array}
\xrightarrow{\gamma \cup \chi} 
\begin{array}{c}
E \\
\downarrow g
\end{array}
\xrightarrow{e} 
\begin{array}{c}
F
\end{array}
\]

A standard argument shows that the lifting problem in the right-hand square can be solved by filling a sequence of inner horns and a single outer horn of shape $\Lambda^{n+1}[n+1]$ whose final edge is the cartesian lift of the degeneracy at $b_n$ to a simplex with domain $e_n$. Lemma 5.1.9 observes that cartesian lifts of degenerate simplices are isomorphisms, so this last horn is actually a “special outer horn” with first edge invertible. Consequently, by Theorem D.4.19 it can therefore be lifted against the isofibration $p$. This construction fills the sphere at the domain end of the hollow cylinder, solving the original lifting problem. □

12.2.12. PROPOSITION (equivalences of co/cartesian fibrations are determined fiberwise). In an $\infty$-cosmos of $(\infty, 1)$-categories, a cartesian functor

\[
\begin{array}{c}
E \\
\downarrow p
\end{array}
\xrightarrow{g} 
\begin{array}{c}
F \\
\downarrow q
\end{array}
\]

between cocartesian fibrations is a fibered equivalence if and only if it is a fiberwise equivalence, meaning that for each $b: 1 \to B$, the induced functor between fibers $g_b: E_b \to F_b$ is an equivalence.

Proof. Again, it is clear that an equivalence of cocartesian fibrations is necessarily a fiberwise equivalence, so we need only prove the converse. By Propositions 10.2.3 and 10.2.2 if $\mathcal{K}$ is an $\infty$-cosmos of $(\infty, 1)$-categories, then the underlying quasi-category functor induces a cosmological biequivalence $(-)_0: \mathcal{K}/B \Rightarrow \mathcal{QCat}/B_0$. By Corollary 10.3.2, this cosmological biequivalence reflects equivalences, and by Proposition 10.3.6 it preserves cocartesian fibrations and cartesian functors between them. Hence, to show that a cartesian functor and fiberwise equivalence $g: E \to F$ is an equivalence over $B$, it suffices to show that $g_0: E_0 \to F_0$ is an equivalence over $B_0$, which we do by verifying that this functor satisfies the hypotheses of Proposition 12.2.11.

By Observation 12.2.2, elements of the underlying quasi-category $B_0$ correspond bijectively to elements of the $\infty$-category $B$, and the cosmological functor $(-)_0: \mathcal{K} \to \mathcal{QCat}$ preserves both fibers.
and equivalences. In this way we see that \( g_0 : E_0 \to F_0 \) is a fiberwise equivalence for all \( b : 1 \to B_0 \). By Proposition 12.2.11 this functor defines a fibered equivalence, and hence \( g \) does as well. □

12.2.13. COROLLARY. In an \( \infty \)-cosmos of \((\infty, 1)\)-categories, a discrete cartesian fibration or discrete cocartesian fibration is a trivial fibration if and only if its fibers are contractible.

Proof. If \( p : E \to B \) is a discrete cartesian or cocartesian fibration, then \( p \) defines a cartesian functor

\[
\begin{array}{ccc}
E & \xrightarrow{p} & B \\
\downarrow q & & \downarrow r \\
A \times B & \xleftarrow{g} & F
\end{array}
\]

whose codomain is the identity discrete fibration. The conclusion now arises as a special case of the result of Proposition 12.2.12 and its dual. □

The result of Proposition 12.2.12 can be extended to modules:

12.2.14. COROLLARY (equivalences of modules are determined fiberwise). In an \( \infty \)-cosmos of \((\infty, 1)\)-categories, a map

\[
\begin{array}{ccc}
E & \xrightarrow{g} & F \\
\downarrow (q,p) & & \downarrow (s,r) \\
A \times B & \xleftarrow{(s,r)} & F
\end{array}
\]

between modules \( E \) and \( F \) from \( A \) to \( B \) is an equivalence if and only if it is a fiberwise equivalence, meaning that for each \( a : 1 \to A \) and \( b : 1 \to B \), the induced functor between the fibers \( g_{a,b} : E(b,a) \to F(b,a) \) is an equivalence.

Proof. Recall from Lemma 7.4.3 that the left-hand legs \( q : E \to A \) and \( s : F \to A \) are cocartesian fibrations and the functor \( g \) defines a cartesian functor between them. It follows, by Proposition 12.2.12, that \( g \) is an equivalence if and only if for each \( a : 1 \to A \), the pullback \( g_a : E(1,a) \to F(1,a) \) is an equivalence. Now each of these \( \infty \)-categories defines a module from \( 1 \) to \( B \), so by Lemma 7.4.3 again, the pullback projections \( p : E(1,a) \to B \) and \( r : F(1,a) \to B \) are cartesian fibrations and \( g_a \) defines a cartesian functor between them. By the dual of Proposition 12.2.12, this functor is an equivalence if and only if for each \( b : 1 \to B \), the induced action \( g_{a,b} : E(b,a) \to F(a,b) \) on fibers is an equivalence. The stated result follows immediately. □

A prototypical special case of this result characterizes units or counits of adjunctions between \((\infty, 1)\)-categories:

12.2.15. COROLLARY. In an \( \infty \)-cosmos of \((\infty, 1)\)-categories, a 2-cell \( \epsilon : fu \Rightarrow id_A \) defines the counit of an adjunction \( f \dashv u \) if and only if the induced functor \( \epsilon \cdot f (\cdot) : \text{Hom}_B(B,u) \to \text{Hom}_A(f,A) \) over \( A \times B \) defines equivalences of internal mapping spaces \( \text{Hom}_B(b,u a) \cong \text{Hom}_A(f b,a) \) for each each \( a : 1 \to A \) and \( b : 1 \to B \).

Corollary 12.2.14 may also be applied to characterize fully faithful functors and equivalences between \((\infty, 1)\)-categories.

12.2.16. PROPOSITION. In an \( \infty \)-cosmos of \((\infty, 1)\)-categories, a functor \( f : A \to B \) is fully faithful if and only if for all elements \( a, a' : 1 \to A \), its action on internal mapping spaces \( f_{a,a'} : \text{Hom}_A(a,a') \to \text{Hom}_B(fa,fa') \) defines an equivalence of discrete \( \infty \)-categories.
Proof. Corollary 3.5.6 defines a functor \( f : A \to B \) to be fully faithful if and only if the induced functor \( A^2 \to \text{Hom}_B(f, f) \) between modules from \( A \) to \( A \) is an equivalence. By Corollary 12.2.14, this is the case if and only if this map defines a fiberwise equivalence, which means exactly that for all elements \( a, a' : 1 \to A \), its action on internal mapping spaces \( f_{a, a'} : \text{Hom}_A(a, a') \to \text{Hom}_B(fa, fa') \) defines an equivalence of discrete \( \infty \)-categories.

We now show that equivalences of \((\infty, 1)\)-categories are precisely those functors that are pointwise fully faithful and essentially surjective in a suitable sense. In [97], Rezk refers to this result as “the fundamental theorem of quasi-category theory.” Our proof mixes synthetic and analytic techniques:

12.2.17. Theorem (fundamental theorem of \((\infty, 1)\)-category theory). In an \( \infty \)-cosmos of \((\infty, 1)\)-categories, a functor \( f : A \to B \) is an equivalence if and only if it is

(i) fully faithful: in the sense that for all elements \( a, a' : 1 \to A \), the induced map

\[
\text{Hom}_A(a, a') \to \text{Hom}_B(fa, fa')
\]

is an equivalence and

(ii) essentially surjective in the sense that for all \( b : 1 \to B \) there exists \( a : 1 \to A \) and an isomorphism \( fa \cong b \) in the homotopy category of \( B \).

Proof. An equivalence of \( \infty \)-categories \( f : A \Rightarrow B \) induces an equivalence of homotopy categories \( h_f : hA \Rightarrow hB \) as well as an equivalence between modules from \( A \) to \( A \), by Propositions 3.3.2 and 3.4.5:

\[
A^2 \xrightarrow{x} \text{Hom}_B(f, f) \xrightarrow{y} B^2
\]

Essential surjectivity is a consequence of the first equivalence, while fully faithfulness follows by pulling the second equivalence back along a pair of elements of \( A \).

To prove the converse, we start by factoring \( f \) as an equivalence followed by an isofibration. Both factors are easily seen to be pointwise fully faithful and essentially surjective, so it suffices to assume that \( f : A \Rightarrow B \) is an isofibration. Our task is now to show that \( f \) is a trivial fibration. In an \( \infty \)-cosmos \( \mathcal{K} \) of \((\infty, 1)\)-categories, the cosmological biequivalence \( (-)_0 : \mathcal{K} \Rightarrow \mathcal{QC}at \) of Proposition 10.2.2 preserves trivial fibration and reflects equivalences. So to show that an isofibration \( f : A \Rightarrow B \) is a trivial fibration, it suffices to show that the underlying isofibration \( f_0 : A_0 \Rightarrow B_0 \) is a trivial fibration, i.e., that we can solve lifting problems of the form

\[
\partial \Delta[n] \xrightarrow{\partial \Delta[n]} \text{Fun}(1, A) \xrightarrow{f_0} \Delta[n] \xrightarrow{f_0} \text{Fun}(1, B)
\]

for \( n \geq 0 \).

When \( f_0 : A_0 \Rightarrow B_0 \) is an isofibration, the hypothesis that \( f : A \Rightarrow B \) is essentially surjective in fact implies that \( f_0 : A_0 \Rightarrow B_0 \) is surjective on vertices. Recall that the homotopy category of \( B \) is defined to be \( hB := h\text{Fun}(1, B) \Rightarrow h(B_0) \). Now Corollary 1.1.16 implies that any isomorphism in the
homotopy category of $B$ can be represented by a homotopy coherent isomorphism $\mathbb{I} \to \text{Fun}(1, B)$. By definition, a map $\Delta[0] \to B_0$ is an element $b: 1 \to B$. A choice of $a: 1 \to A$ and a homotopy coherent isomorphism $\beta: \mathbb{I} \to \text{Fun}(1, B)$ representing $fa \cong b$ defines a lifting problem

\[
\begin{array}{ccc}
\varnothing & \to & \mathbb{I} \\
\downarrow & & \downarrow a \\
\mathbb{I} & \to & \text{Fun}(1, B)
\end{array}
\]

which can be solved by lifting the isomorphism along the isofibration. This solves the lifting problems (12.2.18) in the case $n = 0$.

Applying Proposition 3.4.5 to the commutative diagram below-left, we see that the induced map between modules is an isofibration.

\[
\begin{array}{ccc}
A & = & A \\
\downarrow & & \downarrow f \\
A & \to & B & \leftarrow & A
\end{array}
\quad \sim \quad
\begin{array}{ccc}
A \text{Hom}(A, A) & \to & A \\
\downarrow p_1 & & \downarrow p_1 \\
\text{Hom}_B(f, f) & \to & A
\end{array}
\]

By Proposition 12.2.16 the hypothesis that $f$ is pointwise fully faithful, inducing equivalences between fibers $f_{a,a'}: \text{Hom}_A(a,a') \Rightarrow \text{Hom}_B(fa, fa')$, implies that the induced map $\text{Hom}_A(f, f): A^2 \Rightarrow \text{Hom}_B(f, f)$ is an equivalence and hence under present hypotheses a trivial fibration. The cosmological functor carries this map to a trivial fibration between quasi-categories, which then enjoys the lifting property below-left for $n \geq 0$:

\[
\begin{array}{ccc}
\partial \Delta[n] & \to & (A_0)^2 \\
\downarrow & & \downarrow \text{Hom}_B(f_0, f_0) \\
\Delta[n] & \to & \text{Hom}_B(0, f_0)
\end{array}
\quad \sim \quad
\begin{array}{ccc}
\partial \Delta[n] \times \Delta[1] & \cup & \Delta[n] \times \partial \Delta[1] \\
\downarrow & & \downarrow f_0 \\
\Delta[n] \times \Delta[1] & \to & B_0
\end{array}
\]

Via the description of the comma construction as a weighted limit giving in Example A.6.14, the lifting property above-left transposes across the Leibniz version of the weighted limit two-variable adjunction of Definition A.6.5 to the lifting property displayed above-right, again for $n \geq 0$.

We have already shown that $f_0: A_0 \Rightarrow B_0$ also possesses the right lifting property with respect to the inclusion $\varnothing \hookrightarrow \Delta[0]$. Since this map and the Leibniz product inclusions $(\partial \Delta[n] \hookrightarrow \Delta[n]) \times (\partial \Delta[1] \hookrightarrow \Delta[1])$ generate the class of monomorphisms of simplicial sets under transfinite composition, pushout, and retract, it follows now from the fact that the map $\text{Hom}_{f_0}(A_0, A_0)$ is a trivial fibration that $f_0: A_0 \Rightarrow B_0$ is a trivial fibration. Hence $f: A \Rightarrow B$ is a trivial fibration, which is what we wanted to show.

\[\square\]

**Exercises.**

12.2.i. **EXERCISE.** Use Lemma 12.1.3 to prove the duals of Propositions 12.2.4 and 12.2.11.

12.2.ii. **EXERCISE.** State and prove the duals of Proposition 12.2.6, Corollary 12.2.7, and Corollary 12.2.8.

12.2.iii. **EXERCISE.** Use Corollary 12.2.14 to give a second proof of Proposition 12.2.9(ii).
12.3. Existence of Pointwise Kan Extensions

The vast and rapidly expanding literature on \((\infty, 1)\)-category theory greatly exceeds the scope of this book. We close with a demonstration that illustrates how results whose proofs are found elsewhere can be integrated into the “model-independent” framework of \(\infty\)-cosmoi. In this section, we borrow one result from our colleagues—concerning the “exponentiability” of cartesian and cocartesian fibrations between quasi-categories—and extract a fair amount of mileage from it, as we now illustrate.

The category of simplicial sets, as a category of set-valued presheaves, is \textbf{locally cartesian closed}, meaning that pullback along any map \(f: A \rightarrow B\) of simplicial sets admits a right adjoint, called “pushforward,” as well as a left adjoint, defined by composition:

\[
\begin{array}{c}
\Sigma_f \\
\downarrow \Phi_f \\
\text{sSset}/B \\
\downarrow f^* \\
\text{sSset}/A
\end{array}
\]

\hspace{1cm} (12.3.1)

For some, but not all, isofibrations between quasi-categories, the adjunctions restrict to isofibration-preserving functors

\[
\begin{array}{c}
\Sigma_f \\
\downarrow \Phi_f \\
\text{QCat}/B \\
\downarrow f^* \\
\text{QCat}/A
\end{array}
\]

in which case \(f^*\) and \(\Phi_f\) are both cosmological. Such isofibration \(f: A \rightarrow B\) are called \textbf{exponentiable}. A famously non-exponentiable functor appears in Exercise 12.3.i.

A characterization of the exponentiable functors between quasi-categories due to Lurie, who calls them “flat fibrations,” appears in [77, §B.3]. A model-independent characterization is given by Ayala and Francis in [3, 2.2.8]. Here we require only that the cocartesian fibrations and cartesian fibrations between quasi-categories are among the exponentiable functors, and moreover preserve cartesian and cocartesian fibrations respectively:

\[ \textbf{12.3.2. Theorem (Lurie). In the } \infty \text{-cosmos of quasi-categories:} \]

\[ \text{(i) Cartesian and cocartesian fibrations define exponentiable functors.} \]

\[ \text{(ii) If } q: E \twoheadrightarrow B \text{ is a cocartesian fibration and } p: F \twoheadrightarrow E \text{ is a cartesian fibration, then } \Pi_q p: \Pi_q F \twoheadrightarrow B \text{ is a cartesian fibration and the } \Pi_q p \text{-cocartesian 1-arrows are those maps that transpose to define functors} \]

\[ \begin{array}{c}
\beta \\
\downarrow \beta \\
B \\
\downarrow \beta \\
2
\end{array} \xrightarrow{\chi} \Pi_q F \\
\begin{array}{c}
\beta \\
\downarrow \beta \\
B \\
\downarrow \beta \\
2
\end{array} \xleftarrow{\beta} \Pi_q p
\]

\[ \begin{array}{c}
\hat{\chi} \\
\downarrow \hat{\chi} \\
E_p \\
\downarrow \hat{\chi} \\
F
\end{array} \xleftarrow{p} \begin{array}{c}
\beta \\
\downarrow \beta \\
B \\
\downarrow \beta \\
2
\end{array}
\]

\[ \text{that carry } q \text{-cocartesian lifts of } \beta \text{ to } p \text{-cartesian arrows.} \]

\[ \text{(iii) If } p: E \twoheadrightarrow B \text{ is a cartesian fibration and } q: F \twoheadrightarrow E \text{ is a cocartesian fibration, then } \Pi_p q: \Pi_p F \twoheadrightarrow B \text{ is a cocartesian fibration and the } \Pi_p q \text{-cocartesian 1-arrows are those maps that transpose to define} \]

...
functors

that carry $p$-cartesian lifts of $\beta$ to $q$-cocartesian arrows.

Lurie's proof that cartesian and cocartesian fibrations are exponentiable can be found in [77, B.3.11, B.4.5] while a generalization of the dual pair of results stated as (ii) and (iii) is proven in [77, B.4.2]; a closely related result appears as [74, 3.2.2.12]. A specialization of these results to a setting much closer to the case under consideration here appears as [111, 2.24].

For present purposes, we package these results as follows:

12.3.3. Corollary. For a cocartesian fibration $q: E \rightarrow B$ or cartesian fibration $p: E \rightarrow B$ between quasi-categories, pullback along $q$ or $p$ admits a right adjoint, which restrict to the cosmologically embedded $\infty$-cosmoi

and moreover all of these functors are cosmological.

In fact the restricted cosmological functors again define adjoint functors between the $\infty$-cosmoi of cartesian and cocartesian fibrations. Since the inclusions of these sub $\infty$-cosmoi are not full, the adjointness is not automatic: it remains to argue that the adjoint transpose of a cartesian functor is a cartesian functor. As the proof is somewhat delicate and this result is not needed here, we omit it.

Proof. Theorem 12.3.2(i) tells us that when $p: E \rightarrow B$ is a cartesian or cocartesian fibration, the pushforward functor restricts to define an isofibration-preserving functor $\Pi_p: QC_{/E} \rightarrow QC_{/B}$ between the sliced $\infty$-cosmoi. As a right adjoint, to prove that this functor is cosmological, it remains only to argue that the adjunction $p^* \dashv \Pi_p$ is simplicially enriched. In fact, for any map $f: A \rightarrow B$, the adjunctions in (12.3.1) are simplicially enriched, as can be verified by directly exhibiting the required simplicial natural isomorphism of functor spaces or by applying Proposition A.4.6.

By Lemma 10.1.3 to see that the pushforward functors restrict to the cosmologically embedded $\infty$-cosmoi, it remains to argue that pushforward along a cocartesian fibration $q: E \rightarrow B$ preserves cartesian fibrations and cartesian functors between them, while pushforward along a cartesian fibration $p: E \rightarrow B$ preserves cocartesian fibrations and cartesian functors between them. The object-level assertions are contained in parts (ii) and (iii) of Theorem 12.3.2, so it remains only to argue that cartesian
functors are preserved. To that end, consider a cartesian functor

\[
\begin{array}{ccc}
F & \xrightarrow{g} & G \\
q & \downarrow & r \\
E & \downarrow &
\end{array}
\]

between cocartesian fibrations over \(E\), and suppose \(\chi : 2 \to \Pi_p F\) is a \(\Pi_p q\)-cocartesian 1-arrow. The composite 1-arrow below-left transposes to the composite functor displayed below-right:

\[
\begin{array}{ccc}
2 & \xrightarrow{\chi} & \Pi_p F \\
\downarrow & \downarrow & \downarrow \\
\Pi_p q & \xrightarrow{\Pi_p g} & \Pi_p G \\
\downarrow & \downarrow & \downarrow \\
B & \xrightarrow{\beta} & E
\end{array}
\]

\[
\begin{array}{ccc}
F & \xrightarrow{g} & G \\
\downarrow & \downarrow & \downarrow \\
E & \xrightarrow{\ell} & B \\
\Pi_p & \downarrow & \downarrow \\
\Pi_p q & \xrightarrow{\Pi_p r} & \Pi_p G \\
\downarrow & \downarrow & \downarrow \\
B & \xrightarrow{\beta} & E
\end{array}
\]

By Theorem 12.3.2(iii), the tranposed functor \(\hat{\chi}\) carries \(p\)-cartesian arrows to \(q\)-cocartesian arrows. Since \(g\) is a cartesian functor the composite \(g \hat{\chi}\) carries \(p\)-cartesian arrows to \(r\)-cocartesian arrows. Hence, by Theorem 12.3.2(iii) again, \(g \chi\) is a \(\Pi_p r\)-cocartesian 1-arrow as desired.

We now extend these results to arbitrary \(\infty\)-cosmoi of \((\infty, 1)\)-categories.

12.3.4. Theorem. In an \(\infty\)-cosmos of \((\infty, 1)\)-categories \(\mathcal{K}\):

(i) Pullback along any cartesian fibration or cocartesian fibration \(p : E \to B\) admits a quasi-pseudofunctorial right biadjoint \(\Pi_p\), defining the pushforward of an isofibration along \(p\).

\[
\begin{array}{ccc}
\mathcal{K}_{/E} & \xleftarrow{\perp} & \mathcal{K}_{/B} \\
\Pi_p & \Rightarrow & \Pi_p
\end{array}
\]

\[
\text{Fun}_E(p^*(r), q) \simeq \text{Fun}_B(r, \Pi_p q)
\]

(ii) If \(q : E \to B\) is a cocartesian fibration, then \(\Pi_q\) preserves cartesian fibrations and cartesian functors and restricts to define a quasi-pseudofunctor:

\[
\begin{array}{ccc}
\mathcal{K}_{/E} & \xleftarrow{\perp} & \mathcal{K}_{/B} \\
\Pi_q & \Rightarrow & \Pi_q
\end{array}
\]

\[
\begin{array}{ccc}
\text{Cart}(\mathcal{K})_{/E} & \xleftarrow{\perp} & \text{Cart}(\mathcal{K})_{/B} \\
\Pi_q & \Rightarrow & \Pi_q
\end{array}
\]
(iii) Dually, if \( p : E \to B \) is a cartesian fibration, then \( \Pi_p \) preserves cocartesian fibrations and cartesian functors and restricts to define a quasi-pseudofunctor:

\[
\begin{array}{ccc}
\mathcal{K}_E & \xrightarrow{p^*} & \mathcal{K}_B \\
\downarrow & \Pi_p & \downarrow \\
\text{coCart}(\mathcal{K})_E & \xrightarrow{\sim} & \text{coCart}(\mathcal{K})_B
\end{array}
\]

**Proof.** The pushforward functor \( \Pi_p : \mathcal{K}_E \to \mathcal{K}_B \) is defined as the composite of the pushforward associated to the underlying co/cartesian fibration \( p_0 : E_0 \to B_0 \) between quasi-categories with the zig-zag of cosmological biequivalences

\[
\begin{array}{ccc}
\mathcal{K}_E & \xrightarrow{\Pi_p} & \mathcal{K}_B \\
\downarrow & \approx & \downarrow \\
\text{QC}_0 & \xrightarrow{\Pi_{p_0}} & \text{QC}_0
\end{array}
\]

Note that both pullback and the pushforward commute up to equivalence with the sliced underlying quasi-category functors \( (-)_0 : \mathcal{K}_B \to \text{QC}_0 \).

The composite quasi-pseudofunctor can be understood as a “pointwise right biadjoint,” again appropriating a term from weak 2-category theory, on account of the composite equivalences

\[
\text{Fun}_E(p(r),q) \xrightarrow{(-)_0} \text{Fun}_{E_0}(p_0(r_0),q_0) \cong \text{Fun}_{B_0}(r_0,\Pi_{p_0}(q_0)) \xleftarrow{(-)_0} \text{Fun}_B(r,\Pi_p q)
\]

that are quasi-pseudonaturally defined in \( q : F \to E \) and \( r : G \to B \). This proves the first statement.

The remaining pair of results are dual, so we only supply the argument for the final statement. Let \( p : E \to B \) be a cartesian fibration and let \( q : F \to \hat{E} \) be a cocartesian fibration in \( \mathcal{K} \). Then by Proposition 10.3.6, \( \Pi_p q \) is a cocartesian fibration in \( \mathcal{K} \) if and only if its underlying functor is a cocartesian fibration on quasi-categories. By the essential commutativity of (12.3.5), this functor is equivalent to \( \Pi_{p_0}(q_0) \), which is a cocartesian fibration of quasi-categories by Theorem 12.3.2. Since cocartesian fibrations are replete up to equivalence, the preservation result follows. The proof that pushforward preserves cartesian functors follows similarly from Corollary 12.3.3.

**12.3.6. Lemma (Beck-Chevalley).** Let

\[
\begin{array}{ccc}
F & \xrightarrow{f} & E \\
\downarrow q & & \downarrow p \\
A & \xrightarrow{f} & B
\end{array}
\]

be a pullback diagram in an \( \infty \)-cosmos of \((\infty,1)\)-categories, and suppose that \( p \) is a cocartesian fibration or cartesian fibration. Then for all \( r : G \to E \), the maps \( f \Pi_p r \cong \Pi_q q^* r \) are equivalent over \( A \).
Proof. Applying the cosmological biequivalence $(-)_0: \mathcal{K} \Rightarrow QC\text{at}$ it suffices to prove this for quasi-categories, in which case the functors in question have left adjoints:

$$
\begin{array}{cccc}
\mathcal{K}_F & \overset{\delta^*}{\leftarrow} & \mathcal{K}_E \\
\vdash \Pi_q & & \Pi_p \\
\mathcal{K}_{/A} & \overset{f^*}{\leftarrow} & \mathcal{K}_{/B} \\
\mathcal{QC\text{at}}_{/F_0} & \overset{\delta^*_0}{\leftarrow} & \mathcal{QC\text{at}}_{/E_0} \\
\Pi_{q_0} & & \Pi_{p_0} \\
\mathcal{SET}_{/F_0} & \overset{\Sigma_0}{\leftarrow} & \mathcal{SET}_{/E_0} \\
\Pi_{q_0} & & \Pi_{p_0} \\
\mathcal{SET}_{/A_0} & \overset{\perp}{\leftarrow} & \mathcal{SET}_{/B_0} \\
\delta^*_0 & & f^*_0 \\
\end{array}
$$

For any map of simplicial sets $a: X \rightarrow A_0$, by examining the pullback rectangle

$$
\begin{array}{ccc}
\bullet & \rightarrow & F_0 \overset{\delta^*_0}{\rightarrow} E_0 \\
\downarrow & & \downarrow \\
X & \rightarrow & A_0 \overset{f_0}{\rightarrow} B_0
\end{array}
$$

it is clear that $\Sigma_0\delta^*_0a \cong p_0\Sigma f_0^*a$. Thus, the right adjoints $f_0^*\Pi p_0 \cong \Pi q_0\delta^*_0$ also commute up to isomorphism, and conservativity provides the claimed equivalence in $\mathcal{K}$. □

Now we explain our interest in these results. Recall from Definition 9.1.2 that a right extension of a module $A \stackrel{G}{\Rightarrow} C$ along a module $A \stackrel{E}{\Rightarrow} B$ consists of a pair given by a module $B \overset{\text{hom}_{A(E,F)}}{\Rightarrow} C$ together with a binary cell

$$
\begin{array}{ccc}
A & \overset{E}{\rightarrow} & B \overset{\text{hom}_{A(E,F)}}{\rightarrow} C \\
\parallel & & \parallel \\
A & \overset{G}{\rightarrow} & C
\end{array}
$$

that is universal among the cells in the virtual equipment of modules in a sense detailed there. Dually, a right lifting of $A \overset{G}{\Rightarrow} C$ through $B \overset{F}{\Rightarrow} C$ consists of a pair given by a module $A \overset{\text{hom}(F,G)_C}{\Rightarrow} B$ together with a universal binary cell

$$
\begin{array}{ccc}
A & \overset{\text{hom}(F,G)_C}{\rightarrow} B & \overset{F}{\rightarrow} C \\
\parallel & \parallel \\
A & \overset{G}{\rightarrow} C
\end{array}
$$

Here we’ve deployed different notation for these notions with the aim of rebranding them. We refer to the module $\text{hom}_{A}(E, G)$ has the left hom from $E$ to $F$ and refer to $\text{hom}(F, G)_C$ as the right hom from $F$ and $G$. Extending the “module” metaphor, we think of the left hom as the object of homomorphisms from $E$ to $G$ that respect the left $A$-actions, while the right hom is the object of homomorphisms from $F$ to $G$ that respect the right $C$-actions. Our first aim in this section is to demonstrate that the virtual equipment of modules between quasi-categories has left and right homs for all suitable pairs of modules. By model independence, this result extends to any $\infty$-cosmos of $(\infty, 1)$-categories.

12.3.7. Theorem. The virtual equipment of modules between quasi-categories has left and right homs.
Proof. The cases of left and right homs are dual so we focus on the former. Fixing a module $A \xrightarrow{q} E \xrightarrow{p} B$, define $\text{hom}_A(E, G)$ to be the image of the module $A \xrightarrow{G} C$ under the composite right adjoint functor

$$
\begin{array}{ccc}
\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/A \times C} & \xrightarrow{(q \times C)^*} & \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/E \times C} & \xrightarrow{\Pi_{p \times C}} & \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/B \times C}
\end{array}
$$

Note that the left adjoint carries a span of isofibrations $B \xleftarrow{s} F \xrightarrow{r} C$ to the composite two-sided isofibration:

$$
\begin{array}{ccc}
A & \xleftarrow{q} & E \xrightarrow{p} F \xrightarrow{u} B \xrightarrow{s} M \xrightarrow{v} C
\end{array}
$$

and adjointness provides natural equivalences (or in this case isomorphisms) of quasi-categories

$$
\text{Fun}_{A \times C}(E \times B, F, G) \cong \text{Fun}_{B \times C}(F, \text{hom}_A(E, G)).
$$

These equivalences induce bijections on the sets of isomorphism classes of objects in these quasi-categories. By Proposition 8.1.8, this gives rise to the universal property required by the right hom in the virtual equipment of modules as spelled out in Definition 9.1.2 — at least once we prove that $\text{hom}_A(E, G)$ defines a module under the hypothesis that $E$ and $G$ define modules.

Thus it remains only to show that when $A \xrightarrow{E} B$ is a module, then the functor

$$
\text{hom}_A(E, -) : \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/A \times C} \xrightarrow{(q \times C)^*} \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/E \times C} \xrightarrow{\Pi_{p \times C}} \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/B \times C}
$$

preserves modules. Proposition 7.4.5 tells us that modules are stable under pullback, so we need only demonstrate that $\Pi_{p \times C}$ carries a module $E \xleftarrow{M} C$ to a module from $B$ to $C$. Proposition 7.4.2 characterizes modules from $E$ to $C$ as those two-sided isofibrations $(v, u) : M \rightarrowtail E \times C$ so that

(i) $(v, u) : M \rightarrow E \times C$ is a cocartesian fibration in $\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/C}$,

(ii) $(v, u) : M \rightarrow E \times C$ is a cartesian fibration in $\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/E}$,

(iii) $(v, u) : M \rightarrow E \times C$ is discrete as an object in $\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/E \times C}$.

We will show that $\Pi_{p \times C}$ preserves each of these properties, proving that $\Pi_{p \times C} M$ defines a module from $B$ to $C$. We start with (iii). Corollary 12.3.3 demonstrates that the pushforward is a cosmological functor and Proposition 10.1.7 observes that cosmological functors preserve discrete objects. So (iii) is automatic.

We next turn our attention to (ii), arguing that $\Pi_{p \times C} M \rightarrow B \times C$ is a cartesian fibration in $\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/B}$. First note, by Proposition 10.1.7, that the cosmological functor $\Pi_{p} : \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/E} \rightarrow \mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/B}$ preserves cartesian fibrations\(^5\), so we conclude that $\Pi_{p} M \rightarrowtail \Pi_{p} (B \times C)$ is a cartesian fibration in $\mathcal{Q} \mathcal{C} \mathcal{A} \mathcal{T}_{/B}$. However, this functor does not coincide with $\Pi_{p \times C} M \rightarrow B \times C$. Rather, as demonstrated by Lemma

\(^{5}\)Note this is not an application of Theorem 12.3.4, which in this context would tell us that $\Pi_{p}$ carries a cocartesian fibration over $E$ to a cocartesian fibration over $B$. Rather, this says that $\Pi_{p}$, simply by virtue of being cosmological, carries cartesian fibrations between isofibrations with codomain $E$ to cartesian fibrations between isofibrations with codomain $B$. 

415
12.3.8 below, \( \Pi_{p \times C} M \to B \times C \) is a pullback of \( \Pi_p M \to \Pi_p (B \times C) \) in \( \mathcal{QC}_{/B} \), so by pullback stability of cartesian fibrations, this proves (ii).

For the final property (i), recall from Lemma 7.1.1 that to say that \( (v, u) : M \to E \times C \) defines a cocartesian fibration in \( \mathcal{QC}_{/C} \) is equivalently to say that \( (v, u) : M \to \Pi_p (B \times C) \) defines a morphism in the sub \( \infty \)-cosmos \( \text{coCart}(\mathcal{QC})_{/E} \subset \mathcal{QC}_{/E} \). By Corollary 12.3.3, \( \Pi_p \) restricts to define a cosmological functor \( \Pi_{p \times C} : \mathcal{QC}_{/E \times C} \to \mathcal{QC}_{/B \times C} \). In particular, by Lemma 12.3.8 the pullback \( \Pi_{p \times C} M \to B \times C \) of \( \Pi_p M \to \Pi_p (B \times C) \) lies in the sub cosmos \( \text{coCart}(\mathcal{QC})_{/B} \). By Lemma 7.1.1 again this tells us that \( \Pi_{p \times C} M \to B \times C \) is a cocartesian fibration in \( \mathcal{QC}_{/C} \) as required.  

12.3.8. Lemma. Let \( p : E \to B \) be a cartesian fibration or cocartesian fibration between quasi-categories. Then the image of an isofibration \( M \to E \times C \) under \( \Pi_{p \times C} : \mathcal{QC}_{/E \times C} \to \mathcal{QC}_{/B \times C} \) is the left vertical isofibration defined by the pullback

\[
\begin{array}{ccc}
\Pi_{p \times C} M & \to & \Pi_p M \\
\downarrow & & \downarrow \\
B \times C & \to & \Pi_p (E \times C)
\end{array}
\]

whose right-hand vertical morphism is the image of the map \( M \to E \times C \) under \( \Pi_p : \mathcal{QC}_{/E} \to \mathcal{QC}_{/B} \).

The conclusion of Lemma 12.3.8 holds, up to equivalence, in any \( \infty \)-cosmos of \( (\infty, 1) \)-categories \( \mathcal{K} \); see Exercise 12.3.iii. However, we find it easier to work with the strict adjunction of Corollary 12.3.3 rather than the weaker adjunctions of Theorem 12.3.4.

Proof. To make sense of the statement note that \( p^* \) carries \( \pi : B \times C \to B \) to \( \pi : E \times C \to E \). Hence the map \( \eta : B \times C \to \Pi_p (E \times C) \) is a component of the unit of the adjunction \( p^* \dashv \Pi_p \). Now the claim follows directly by verifying that the displayed pullback has the universal property that defines \( \Pi_{p \times C} M \in \mathcal{QC}_{/B \times C} \). A cone over the pullback diagram may be interpreted as a diagram

\[
\begin{array}{ccc}
X & \to & \Pi_p M \\
\downarrow & & \downarrow \\
B \times C & \to & \Pi_p (E \times C)
\end{array}
\]

in \( \mathcal{QC}_{/B} \), which then transposes to define a commutative square

\[
\begin{array}{ccc}
X \times_B E & \to & M \\
\downarrow & & \downarrow \\
E \times C & \to & E \times C
\end{array}
\]

in \( \mathcal{QC}_{/E} \). In fact, this diagram lies in \( \mathcal{QC}_{/E \times C} \) and the left-hand vertical map \( X \times_B E \to E \times C \) is isomorphic to \( (p \times C)^* (X \to B \times C) \). Hence, this square transposes along \( (p \times C)^* \dashv \Pi_{p \times C} \) to a commutative square

\[
\begin{array}{ccc}
X & \to & \Pi_{p \times C} M \\
\downarrow & & \downarrow \\
B \times C & \to & B \times C
\end{array}
\]
which proves the claim.

The result of Theorem 12.3.7 extends to biequivalent ∞-cosmoi:

12.3.9. Corollary. In any ∞-cosmos of (∞, 1)-categories, the virtual equipment of modules has left and right homs.

There are two strategies for proving this. The first is to prove the model-independence of the ingredients used in the proof of Theorem 12.3.7, such as appealing to Theorem 12.3.4 in place of Corollary 12.3.3. A more expedient, though ultimately less informative strategy, is to simply make use of the biequivalence of virtual equipments, which is the approach we take here.

Proof. Consider modules $A \xrightarrow{E} B$ and $A \xrightarrow{G} C$ in an ∞-cosmos of (∞, 1)-categories. By Theorem 11.2.6, there exists a module $B \xrightarrow{R} C$, whose image under the underlying quasi-category functor is equivalent to the left hom $\text{Hom}_{A_0}(E_0, G_0)$ of Theorem 12.3.7, and binary cell $\nu: E \times R \Rightarrow G$ whose image under the underlying quasi-category functor composes with this equivalence to the binary map of modules between quasi-categories that defines the left hom from $E_0$ to $G_0$. It remains only to argue that this data has the universal property of a right extension in $\text{Mod}(\mathcal{K})$, but this follows from the biequivalence of virtual equipments $(-)_0: \text{Mod}(\mathcal{K}) \cong \text{Mod}(\mathcal{QCat})$.

Left and right homs can be used to define modules that encode universal properties in ∞-category theory. When the modules so-constructed are covariantly or contravariantly represented by a functor, as appropriate, then this data “satisfies the universal property,” as we now illustrate. Proposition 9.5.3 observes that the value of a pointwise right extension of a functor $f: A \to E$ along a functor $k: A \to B$ at an element $b: 1 \to B$ is the limit of the composite diagram

$\text{Hom}_B(b, k) \xrightarrow{\text{pr}_1} A \xrightarrow{f} E$

The dual result demonstrates that the value of a pointwise left extension of $f$ along $k$ at $b$ is a colimit of the restriction of the functor $f$ along $\pi_0: \text{Hom}_B(k, b) \to A$.

We will now prove that in an ∞-cosmos of (∞, 1)-categories, if an ∞-category $E$ admits such limits, then the pointwise right extension of $f$ along $k$ exists. The dual result reduces the question of the existence of pointwise left extensions to the existence of certain colimits.

12.3.10. Theorem (existence of pointwise right extensions). Let $k: A \to B$ be a functor in an ∞-cosmos of (∞, 1)-categories and let $C$ be an ∞-category that admits $\text{Hom}_B(b, k)$-shaped limits for all elements $b: 1 \to B$. Then $C$ admits pointwise right extensions along $k$

$\xymatrix{ A \ar[r]^f & C \\
B \ar[u]^k \ar[ur]_{\text{rank } f} & \ar[u]_{\text{pr}_1} }$

Proof. Consider the module $\text{Hom}_B(B, k)$ from $A$ to $B$ covariantly represented by the functor $k: A \to B$. Corollary 12.3.9 proves that any ∞-cosmos of (∞, 1)-categories admits left and right homs, defining right extensions and right liftings in the virtual equipment of modules. In particular given
any diagram $f : A \to C$, there exists a right extension in the virtual equipment of modules

$$
\begin{array}{cccccc}
A & \xrightarrow{\text{Hom}_B(B,k)} & B & \xrightarrow{\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))} & C \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
A & \xrightarrow{\text{Hom}_C(C,f)} & C
\end{array}
$$

Now the $\infty$-category $C$ will admit a pointwise right Kan extension of $f : A \to C$ along $k : A \to B$ just when the module $\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))$ is covariantly represented by a functor $r : B \to C$. By Corollary 12.2.8, this module is covariantly represented if and only if its pullbacks along each vertex $b : 1 \to B$ are covariantly represented, which is the case just when the fiber of the module $\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f)) \to B \times C$ over $b$ has a terminal element.

By Lemma 9.1.4 the fiber $\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))(1,b)$ arises as the the right extension

$$
\begin{array}{cccccc}
B & \xrightarrow{\text{Hom}_B(B,k)} & 1 & \xrightarrow{\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))(1,b)} & C \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
B & \xrightarrow{\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))} & C
\end{array}
$$

Since $\text{Hom}_B(B,k) \otimes \text{Hom}_B(b,B) \cong \text{Hom}_B(b,k)$ by Proposition 8.4.7, Proposition 9.1.6 allows us to combine these two right extensions into a single one

$$
\begin{array}{cccccc}
A & \xrightarrow{\text{Hom}_B(b,k)} & 1 & \xrightarrow{\text{hom}_A(\text{Hom}_B(B,k),\text{Hom}_C(C,f))(1,b)} & C \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
A & \xrightarrow{\text{Hom}_C(C,f)} & C
\end{array}
$$

By exactness of the comma square

we also have a composition relation $\text{Hom}_A(p_1, A) \otimes \text{Hom}_1(1, !) \cong \text{Hom}_B(b,k)$. By Lemma 9.1.4, there is a right extension diagram

$$
\begin{array}{cccccc}
A & \xrightarrow{\text{Hom}_A(p_1,A)} & \text{Hom}_B(b,k) & \xrightarrow{\text{Hom}_C(C,f_1)} & C \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
A & \xrightarrow{\text{Hom}_C(C,f)} & C
\end{array}
$$

418
So by Proposition 9.1.6, since $\text{Hom}_C(C, f)$ admits a right extension along $\text{Hom}_A(p_1, A) \otimes \text{Hom}_1(1, !)$, the right extension of $\text{Hom}_C(C, fp_1)$ along $\text{Hom}_1(1, !)$ exists and is given by

$$
\begin{array}{ccc}
\text{Hom}_A(b, k) & \xrightarrow{\text{Hom}_1(1, !)} & 1 \\
\downarrow & & \downarrow \\
\text{Hom}_C(b, k) & \xrightarrow{\text{Hom}_1(1, !)} & C
\end{array}
$$

In summary, the fiber of the module $\text{Hom}_A(\text{Hom}_B(b, k), \text{Hom}_C(C, f))$ over $b: 1 \to B$ is the module defined by the right extension of $\text{Hom}_C(C, fp_1)$ along $\text{Hom}_1(1, !)$. Thus, we see that if this module is represented by an element $c: 1 \to C$, that element defines a pointwise right extension of the diagram

$$
\begin{array}{ccc}
\text{Hom}_B(b, k) & \xrightarrow{p_1} & A \\
\downarrow & & \downarrow \\
1 & \xrightarrow{f} & C
\end{array}
$$

By Definition 9.5.1, this exists if and only if the diagram $fp_1: \text{Hom}_B(b, k) \to C$ has a limit in $C$. As we have assumed that this limit exists in $C$, so does the pointwise right extension of $f$ along $k$, as claimed.

Recall from Observation 10.3.4 that any $\infty$-cosmos of $(\infty, 1)$-categories admits weakly-defined exponentials.

12.3.11. COROLLARY. Let $k: A \to B$ be a functor in an $\infty$-cosmos of $(\infty, 1)$-categories and let $C$ be an $\infty$-category that admits $\text{Hom}_B(b, k)$-shaped limits for all elements $b: 1 \to B$. Then pointwise right extension defines a right adjoint to the restriction functor:

$$
\begin{array}{ccc}
C^A & \xleftarrow{- \circ k} & C^B \\
\downarrow \text{ran}_k \\
1 & \xrightarrow{f} & C^A
\end{array}
$$

PROOF. By Lemma 2.3.6, to define a right adjoint to restriction it suffices to define an absolute right lifting of the identity through the functor $- \circ k: C^B \to C^A$. By Proposition 12.2.9, to achieve this it suffices to define absolute right lifting diagrams

$$
\begin{array}{ccc}
C^B & \xrightarrow{\text{ran}_f} & C^A \\
\downarrow \nu & & \downarrow \nu \\
1 & \xrightarrow{f} & C^A
\end{array}
$$

for all elements $f: 1 \to C^A$ of $C^A$. As our notation suggests, we will demonstrate that the pointwise right extension $\nu: \text{ran}_f \circ k \Rightarrow f$ of Theorem 12.3.10 transposes across the equivalence $\text{hFun}(X, C^A) \simeq \text{hFun}(X \times A, C)$ of Observation 10.3.4 to define an absolute right lifting diagram. This follows immediately from Exercise 9.5.i, which we now belatedly solve.
The universal property that characterizes the absolute right lifting diagram

\[
\begin{array}{ccc}
X & \xrightarrow{e} & C^B \\
\downarrow & & \downarrow \exists \xi \\
D & \xrightarrow{f} & C^A
\end{array}
\quad = \quad
\begin{array}{ccc}
X & \xrightarrow{e} & C^B \\
\downarrow & & \downarrow \exists \xi \\
1 & \xrightarrow{f} & C^A
\end{array}
\]

where we have written \( r := \text{ran}_k f \) transposes to

\[
\begin{array}{ccc}
A \times X & \xrightarrow{\pi \times \pi} & A \times C \\
\downarrow k \times X & & \downarrow \exists \xi \\
B \times X & \xrightarrow{e} & B \times C
\end{array}
\quad = \quad
\begin{array}{ccc}
A \times X & \xrightarrow{\pi \times \pi} & A \times C \\
\downarrow k \times X & & \downarrow \exists \xi \\
B \times X & \xrightarrow{e} & B \times C
\end{array}
\]

Lemma 9.2.9 proves that the pullback square is exact. Now if \( \nu \) is a pointwise right extension, then by Lemma 9.2.9 and Corollary 9.3.4 so is \( \nu \circ \pi \). The transposed universal property of this right extension diagram proves that \( \nu \) defines an absolute right lifting. \( \square \)

The argument just given shows something further. By Corollary 9.3.4, the pasted composite of a pointwise right extension \( \nu \) with an exact square \( \phi \) gives another pointwise right extension as below-left, which we have just shown transposes to define an absolute right-lifting diagram below-right:

\[
\begin{array}{ccc}
E & \xrightarrow{p} & A \xrightarrow{f} C \\
\downarrow q & & \downarrow \nu \\
D & \xrightarrow{h} B
\end{array}
\quad \leftrightarrow \quad
\begin{array}{ccc}
C^B & \xrightarrow{\phi} & C^D \\
\downarrow k \circ \nu & & \downarrow \exists \xi \\
C^A & \xrightarrow{\phi} & C^E
\end{array}
\]

This proves the second part of Exercise 9.5.i: that the absolute right lifting diagrams that arise as transposes of pointwise right extension diagrams are stable under pasting with exponentiated exact squares. In particular, if \( C \) admits pointwise right extensions along \( k : A \to B \) then for any exact square \( \phi \) we have an absolute right lifting diagram

\[
\begin{array}{ccc}
C^B & \xrightarrow{\phi} & C^D \\
\downarrow \nu \circ k & & \downarrow \exists \xi \\
C^A & \xrightarrow{\phi} & C^E
\end{array}
\quad \Rightarrow \quad
\begin{array}{ccc}
C^B & \xrightarrow{\phi} & C^D \\
\downarrow \nu \circ k & & \downarrow \exists \xi \\
C^A & \xrightarrow{\phi} & C^E
\end{array}
\]

since by Proposition 12.2.9 the universal property of this absolute right lifting diagram can be checked pointwise at elements \( f : 1 \to C^A \). Using this, we can establish a derivator-style “Beck-Chevalley condition” as follows:
12.3.12. Proposition (Beck-Chevalley condition). For any exact square
\[
\begin{array}{ccc}
D & \xrightarrow{p} & B \\
\downarrow q & & \downarrow \phi & \downarrow f \\
C & \xleftarrow{\phi} & B \\
\downarrow \phi & & \downarrow \phi \\
A & \xleftarrow{f} & B
\end{array}
\]
in an \(\infty\)-cosmos of \((\infty,1)\)-categories and any \(\infty\)-category \(E\), the mates \(\phi^!\) and \(\phi_*\) of the induced natural transformation \(\phi^*\) are both isomorphisms whenever these pointwise right and left extensions exist.

**Proof.** By Corollary 12.3.11, the pointwise right extensions assemble into adjoint functors \(\text{ran}_g\) and \(\text{ran}_p\) which define absolute right lifting diagrams

Moreover, the mate \(\phi^!\) of \(\phi^*\) defines a factorization of the left-hand diagram through the right-hand diagram:

 Immediately from the universal property of the absolute right liftings of \(q^*\) through \(p^*\) we have that \(\phi^!\) is an isomorphism. The proof for \(\phi_*\) is similar using the absolute left lifting diagrams arising from the pointwise left extensions defining \(\text{lan}_f\) and \(\text{lan}_q\).

**Exercises.**

12.3.i. Exercise. Conclude from the pullback diagram of simplicial sets

\[
\begin{array}{ccc}
1 + 1 & \longrightarrow & \Lambda^1[2] \\
\downarrow d & & \downarrow \iota \\
2 & \longrightarrow & 3 \\
\end{array}
\]
that the functor \(d^1: 2 \rightarrow 3\) is not exponentiable.
12.3.ii. **Exercise.** Suppose $A \xrightarrow{E} B$, $A \xrightarrow{G} C$, and $B \xrightarrow{R} C$ are modules equipped with a natural equivalence $\text{Fun}_{A \times C}(E \times_B F, G) \simeq \text{Fun}_{B \times C}(F, R)$ for all two-sided fibrations $F$ from $B$ to $C$. Extract a binary cell $\nu: E \times R \Rightarrow G$ from this natural equivalence and prove that $\nu$ exhibits $R$ as a right extension of $G$ along $E$.

12.3.iii. **Exercise.** Adapt Lemma 12.3.8 to a model-independent statement that applies in any $\infty$-cosmos of $(\infty, 1)$-categories and then prove this result. Then use this to adapt the proof of Theorem 12.3.7 to directly demonstrate that any $\infty$-cosmos of $(\infty, 1)$-categories has all left and right homs.

12.3.iv. **Exercise.** Suppose $C$ is an $\infty$-category in an $\infty$-cosmos of $(\infty, 1)$-categories that is complete in the sense that it admits limits indexed by all small simplicial sets. Use Proposition 10.3.5 to show that for any map $k: A \rightarrow B$ between small simplicial sets, the restriction functor has a right adjoint that we might call right Kan extension:

$$C^A \xrightarrow{- \circ k} \downarrow_{\text{ran}_k} C^B$$
Appendix of Abstract Nonsense
Basic Concepts of Enriched Category Theory

Enriched category theory exists because enriched categories exist in nature. To explain, consider the data of a 1-category $\mathcal{C}$, given by:

- a collection of objects
- for each pair of objects $x, y \in \mathcal{C}$, a set $\mathcal{C}(x, y)$ of arrows in $\mathcal{C}$ from $x$ to $y$
- for each $x \in \mathcal{C}$, a specified identity element $\text{id}_x : 1 \to \mathcal{C}(x, x)$, and for each $x, y, z \in \mathcal{C}$, a specified composition map $\circ : \mathcal{C}(y, z) \times \mathcal{C}(x, y) \to \mathcal{C}(x, z)$ satisfying the associativity and unit conditions:

$$\begin{align*}
\mathcal{C}(y, z) \times \mathcal{C}(x, z) \times \mathcal{C}(w, x) &\to \mathcal{C}(x, z) \\
\text{id} \times \text{id} &\to \text{id}
\end{align*}$$

In many mathematical examples of interest, the set $\mathcal{C}(x, y)$ can be given additional structure, in which case it would be strange not to take it account when performing further categorical constructions.

Perhaps there exists a specified zero arrow $0_{x,y} \in \mathcal{C}(x, y)$ in each hom-set, defining a two-sided ideal for composition: $g \circ 0 \circ f = 0$. Or extending this, perhaps each $\mathcal{C}(x, y)$ admits an abelian group structure, for which composition is $\mathbb{Z}$-bilinear. Or in another direction, perhaps the set of arrows from $x$ to $y$ in $\mathcal{C}$ form the objects of a 1-category. In this setting, we regard the objects of $\mathcal{C}(x, y)$ as “1-dimensional” morphisms from $x$ to $y$ and the arrows of $\mathcal{C}(x, y)$ as “2-dimensional” morphisms from $x$ to $y$ in $\mathcal{C}$; here, it is natural to require the composition map to define a functor. Or perhaps the set of arrows from $x$ to $y$ in $\mathcal{C}$ form the vertices of a simplicial set, whose higher simplices now provides arrows in each positive dimension; here, it is natural to ask composition to define a simplicial map. In all of these contexts, one says that the 1-category $\mathcal{C}$ can be enriched over the category $\mathcal{V}$ in which the objects $\mathcal{C}(x, y)$ and diagrams (A.0.1) live — with $\mathcal{V}$ equal to the category of pointed sets, abelian groups, categories, or simplicial sets in the examples just described.

An alternate point of view of enriched category theory is often emphasized — adopted for instance in the classic textbook [67] from which we stole the title of this chapter. To borrow a distinction used by Peter May, the term “enriched” can be used as a compound noun — enriched categories — or as an adjective — enriched categories. In the noun form, an enriched category $\mathcal{C}$ has no pre-existing underlying ordinary category, although we shall see below that the underlying unenriched 1-category can always be identified a posteriori. When used as an adjective, an enriched category $\mathcal{C}$ is perhaps

---

1 Confusingly, this diagram contains two different sorts of identity arrows: e.g., the top horizontal arrow is the product of the specified identity element $\text{id}_x : 1 \to \mathcal{C}(x, x)$ with the identity arrow associated to the object $\mathcal{C}(x, y)$.

2 To interpret the diagrams (A.0.1) in $\mathcal{V}$ one needs to specify an interpretation for the monoidal product “×” and its unit object $1$ (which is not displayed in the diagram). In the examples we will consider, this product is the cartesian product and this unit is the terminal object.
most naturally an ordinary category, whose hom-sets can be given additional structure.³ While the noun perspective is arguably more elegant when discussing the general theory of enriched categories, the adjective perspective dominates when discussing examples, so we choose to emphasize the adjective form and focus on enriching unenriched categories here.

Before giving a precise definition of enriched category and the enriched functors between them in §A.2, in §A.1 we study that category \( \mathcal{V} \) that defines the base for enrichment in which the hom-objects will ultimately live. Here we are interested primarily in two examples \( \mathcal{V} = \text{Cat} \) and \( \mathcal{V} = \text{sSet} \), as well as the unenriched case \( \mathcal{V} = \text{Set} \), each of which has the special property of being cartesian closed categories. Since there are some simplifications in enriching over a cartesian closed category, we grant ourselves the luxury of working explicitly with this notion.⁴

We continue in §A.3 with an introduction to enriched natural transformations and the enriched Yoneda lemma. These notions allow us to correctly state the universal properties that characterize cotensors and tensors in §A.4 and conical limits and colimits in §A.5, both of which are characterized by universal properties involving an enriched natural isomorphism. These are each special cases of weighted limits and colimits, which are introduced in §A.6. We conclude in §A.7 with a general theory of “change of base” — the one part of the theory of enriched categories that is not covered in encyclopedic detail in [67], the original reference instead being [40] — which allows us to be more precise about the procedure by which a 2-category may be regarded as a simplicial category or by which a simplicial category may be quotiented to define a 2-category (see e.g., Definition 1.4.1) as alluded to in Digression 1.4.2.

### A.1. Cartesian Closed Categories

Throughout this text, the base category for enrichment will always be taken to be a complete and cocomplete cartesian closed category:

#### A.1.1. Definition. A category \( \mathcal{V} \) is cartesian closed when it

- admits finite products, or equivalently, a terminal object \( 1 \in \mathcal{V} \) and binary products and
- for each \( v \in \mathcal{V} \), the functor \( \cdot \times v : \mathcal{V} \to \mathcal{V} \) admits a right adjoint \( (-)^v : \mathcal{V} \to \mathcal{V} \).

#### A.1.2. Lemma. In a cartesian closed category \( \mathcal{V} \), the product bifunctor is the left adjoint of a two-variable adjunction, this being captured by a commutative triangle of natural isomorphisms

\[
\begin{align*}
\mathcal{V}(a \times b, c) & \cong \mathcal{V}(a, c^b) \\
& \cong \mathcal{V}(b, c^a)
\end{align*}
\]  

(A.1.3)

**Proof.** The family of functors \((-)^a : \mathcal{V} \to \mathcal{V}\) extend to bifunctors

\[
(-)^a : \mathcal{V}^{op} \times \mathcal{V} \to \mathcal{V}
\]

in a unique way so that the isomorphism defining each adjunction \(a \times - \dashv (-)^a\)

\[
\mathcal{V}(a \times b, c) \cong \mathcal{V}(b, c^a)
\]

³To quote [82] “Thinking from the two points of view simultaneously, it is essential that the constructed ordinary category be isomorphic to the ordinary category that one started out with. Either way, there is a conflict of notation between that preferred by category theorists and that in common use by ‘working mathematicians’ (to whom [79] is addressed).”

⁴More generally, a category can be enriched over a monoidal category [67], a bicategory [16], or a virtual double category [72], generalizing the preceding bases for enrichment.
becomes natural in $a$ (as well as $b$ and $c$). The details are left as Exercise A.1.i or to [99, 4.3.6]. This defines the natural isomorphism on the right-hand side of (A.1.3). The natural isomorphism on the left-hand is defined by composing with the symmetry isomorphism $a \times b \cong b \times a$. The third natural isomorphism is taken to be the composite of these two. 

\[ \text{□} \]

A.1.4. Example (cartesian closed categories).

(i) The category of sets is cartesian closed, with $B^A$ defined to be the set of functions from $A$ to $B$. Transposition across the natural isomorphism (A.1.3) is referred to as “currying.”

(ii) The category $\text{Cat}$ of small categories is cartesian closed, with $B^A$ defined to be the category of functors and natural transformations from $A$ to $B$.\(^5\) The natural isomorphism

$$\text{Cat}(A, C^B) \cong \text{Cat}(A \times B, C) \cong \text{Cat}(B, C^A)$$

identifies natural transformations, which are arrows $2 \to C^A$ in the category of functors, with “directed homotopies” $A \times 2 \to C$.

(iii) For any small category $C$, the category $\text{Set}^{\text{Cop}}$ is cartesian closed. By the Yoneda lemma for $F, G \in \text{Set}^{\text{Cop}}$, the value of $G^F$ at $c \in C$ must be defined by

$$G^F(c) \cong \text{Set}^{\text{Cop}}(\text{C}(\cdot, c), G^F) \cong \text{Set}^{\text{Cop}}(F \times \text{C}(\cdot, c), G)$$

to be the set of natural transformations $F \times \text{C}(\cdot, c) \to G$. As in the proof of Lemma A.1.2, the action of $G^F$ on a morphism $f : c \to c' \in C$ is defined by precomposition with the corresponding natural transformation $f_* : \text{C}(\cdot, c) \to \text{C}(\cdot, c')$. This defines the functor $G^F$.

Since any functor $H \in \text{Set}^{\text{Cop}}$ is canonically a colimit of representables, this definition extends to the required natural isomorphism $\text{Set}^{\text{Cop}}(H, G^F) \cong \text{Set}^{\text{Cop}}(F \times H, G)$.

(iv) In particular taking $C = \Delta^{\text{op}}$, the category of simplicial sets $\text{sSet} := \text{Set}^{\Delta^{\text{op}}}$ is cartesian closed.

The exponential $b^a$ is frequently referred to as an internal hom. As this name suggests, the internal hom $b^a$ can be viewed as a lifting of the hom-set $\text{V}(a, b)$ along a functor that we now introduce.

A.1.5. Definition. For any cartesian closed category $\text{V}$, the underlying set functor is the functor

$$\text{V} \xrightarrow{(\cdot)_0 : \text{V}(1, \cdot)} \text{Set}$$

represented by the terminal object $1 \in \text{V}$.

A.1.6. Lemma. For any pair of objects $a, b \in \text{V}$ in a cartesian closed category, the underlying set of the internal hom $b^a$ is $\text{V}(a, b)$, i.e.:

$$b^a
\text{(0)} \cong \text{V}(a, b).$$

Proof. Combining Definition A.1.5 with (A.1.3):

$$(b^a)_0 := \text{V}(1, b^a) \cong \text{V}(1 \times a, b) \cong \text{V}(a, b)$$

since there is a natural isomorphism $1 \times a \cong a$. \[ \text{□} \]

It makes sense to ask whether an isomorphism of underlying sets can be “enriched” to lie in $\text{V}$, that is, lifted along the underlying set functor $(-)_0 : \text{V} \to \text{Set}$.

\(^5\)Size matters here: the category of large but locally small categories is not cartesian closed, though it is still possible to define $B^A$ in the case where $A$ is a small category.
Lemma. The natural isomorphisms (A.1.3) characterizing the defining two-variable adjunction of a cartesian closed category lift to $\mathcal{V}$: for any $a, b, c \in \mathcal{V}$

\[
\begin{align*}
(c^a)^b & \cong (c^b)^a & \cong (c^a)^b
\end{align*}
\]  

(A.1.8)

Proof. This follows from Lemma A.1.2, the associativity of finite products, and the Yoneda lemma. To prove (A.1.8), it suffices to show that $c^{a \times b}$, $(c^b)^a$, and $(c^a)^b$ represent the same functor. We have a sequence of natural isomorphisms:

\[
\begin{align*}
\mathcal{V}(x, (c^b)^a) & \cong \mathcal{V}(x \times a, c^b) \\
&\cong \mathcal{V}((x \times a) \times b, c) \cong \mathcal{V}(x \times (a \times b), c) \\
&\cong \mathcal{V}(x, c^{a \times b}) \\
&\cong \mathcal{V}((a \times b) \times x, c) \cong \mathcal{V}(a \times (b \times x), c) \\
&\cong \mathcal{V}(b \times x, c^a) \\
&\cong \mathcal{V}(x, (c^a)^b),
\end{align*}
\]

and hence

\[
\mathcal{V}(x, (c^b)^a) \cong \mathcal{V}(x, c^{a \times b}) \cong \mathcal{V}(x, (c^a)^b). \quad \Box
\]

Remark. Note $(-)^1: \mathcal{V} \to \mathcal{V}$ is naturally isomorphic to the identity functor — i.e., $b^1 \cong b$, — since it is right adjoint to a functor $- \times 1: \mathcal{V} \to \mathcal{V}$ that is naturally isomorphic to the identity.

A bicomplete cartesian closed category is a special case of a complete and cocomplete closed symmetric monoidal category, this being deemed a cosmos by Bénabou, to signify that such bases are an ideal setting for enriched category theory. For obvious reasons, we won’t use this term here and will instead refer to complete and cocomplete cartesian closed categories to describe some of the common features of the categories appearing in Example A.1.4.

Exercises.

Exercise. Prove that in a cartesian closed category $\mathcal{V}$, the family of functors $(-)^a: \mathcal{V} \to \mathcal{V}$ extend to bifunctors

\[
(-)^{-}: \mathcal{V}^{\text{op}} \times \mathcal{V} \to \mathcal{V}
\]

in a unique way so that the isomorphism defining each adjunction $a \times - \dashv (-)^a$

\[
\mathcal{V}(a \times b, c) \cong \mathcal{V}(b, c^a)
\]

becomes natural in $a$ (as well as $b$ and $c$).

Exercise. The data of a closed symmetric monoidal category generalizes Definition A.1.1 by replacing finite products by an arbitrary bifunctor $- \otimes -: \mathcal{V} \times \mathcal{V} \to \mathcal{V}$, replacing the terminal object by an object $I \in \mathcal{V}$, and requiring the additional specification of natural isomorphisms

\[
\begin{align*}
(a \otimes (b \otimes c) & \cong (a \otimes b) \otimes c \\
I \otimes a & \cong a \otimes I \\
a \otimes b & \equiv b \otimes a
\end{align*}
\]

satisfying various coherence axioms [40, 64]: see also [65]. Explain why these isomorphisms do not need to specified in the special case of a cartesian closed category and why the coherence conditions are automatic.
A.2. Enriched Categories and Enriched Functors

We now briefly switch perspectives and explain the meaning of the noun phrase “enriched category” before discussing what is required to “enrich” an ordinary 1-category. From here through §A.6, we fix a cartesian closed category \((\mathcal{V}, \times, 1)\) to serve as the base for enrichment.

A.2.1. Definition. A \(\mathcal{V}\)-enriched category \(\mathcal{C}\) is given by:

- a collection of objects
- for each pair of objects \(x, y \in \mathcal{C}\), an object of arrows \(C(x, y) \in \mathcal{V}\)
- for each \(x \in \mathcal{C}\), a specified identity element encoded by a map \(\text{id}_x : 1 \to C(x, x) \in \mathcal{V}\), and for each \(x, y, z \in \mathcal{C}\), a specified composition map \(\circ : C(y, z) \times C(x, y) \to C(x, z) \in \mathcal{V}\) satisfying the associativity and unit conditions, both commutative diagrams lying in \(\mathcal{V}\):

\[
\begin{align*}
C(y, z) \times C(x, y) \times C(w, x) &\xrightarrow{\text{id} \times \circ} C(z, x) \times C(w, x) \\
C(y, z) \times C(w, y) &\xrightarrow{\circ} C(w, z)
\end{align*}
\]

\[
\begin{align*}
C(x, y) &\xrightarrow{\text{id} \times \text{id}} C(x, y) \times C(x, x) \\
C(y, x) &\xrightarrow{\circ} C(x, y)
\end{align*}
\]

Evidently from the diagrams of (A.0.1), a locally-small 1-category defines a category enriched in \(\mathcal{S}et\). The underlying set functor of Definition A.1.5 can be used to define the “underlying category” of an enriched category.

A.2.2. Definition. If \(\mathcal{C}\) is a \(\mathcal{V}\)-category, its underlying category \(\mathcal{C}_0\) is the 1-category with the same collection of objects and with hom-sets defined by applying the underlying set functor \((-)_0 : \mathcal{V} \to \mathcal{S}et\) to the hom-objects \(C(x, y) \in \mathcal{V}\). For the most part, we write “\(C(x, y)\)” for both the hom-object and the hom-set and use our words to disambiguate, but when necessary “\(C(x, y)_0\)” is also commonly used notation for the hom-set of the underlying category.

Note the identity arrow \(\text{id}_x : 1 \to C(x, x)\) of the \(\mathcal{V}\)-category is by definition an element of the hom-set \(C(x, x)_0 := \mathcal{V}(1, C(x, x))\). The composite of two arrows \(f : 1 \to C(x, y)\) and \(g : 1 \to C(y, z)\) in the underlying category is defined to be the arrow constructed as the composite

\[
1 \xrightarrow{g \times f} C(y, z) \times C(x, y) \xrightarrow{\circ} C(x, z)
\]

In analogy with the discussion around Definition A.1.5, when one speaks of “enriching” an a priori unenriched category \(\mathcal{C}\) over \(\mathcal{V}\), the task is to define a \(\mathcal{V}\)-enriched category as in Definition A.2.1 whose underlying category recovers \(\mathcal{C}\). When \(\mathcal{V} = \text{Cat}\), the task is to define a 2-category whose underlying 1-category is the one given. When \(\mathcal{V} = \mathcal{S}et\), the task is define simplicial hom-sets of \(n\)-arrows so that the 0-arrows are the ones given. When a simplicially enriched category \(\mathcal{C}\) is encoded as a simplicial object \(\mathcal{C}_\bullet\) in \(\text{Cat}\) as explained in Digression 1.2.4, its underlying category is the category \(\mathcal{C}_0\), further justifying the notion introduced in Definition A.2.2.

For example, a cartesian closed category \(\mathcal{V}\) as in Definition A.1.1 can be enriched to define a \(\mathcal{V}\)-category.

A.2.3. Lemma. A cartesian closed category \(\mathcal{V}\) defines a \(\mathcal{V}\)-category whose:

- objects are the objects of \(\mathcal{V}\),

These diagrams suppress the associativity and unit natural isomorphisms involving the product bifunctors \(\times\) and its unit object \(1\). In a cartesian closed category these are canonical — rather than given by extra data, as is the case in the more general closed symmetric monoidal category; see Exercise A.1.ii.
• hom-object in \( \mathcal{V} \) from \( a \) to \( b \) is given by the internal hom \( b^a \), and

• the identity map \( \text{id}_a \colon 1 \to a^a \) and composition map \( \circ \colon b^a \times a \to a^a \) are defined to be the transposes of

\[
1 \times a \to a \quad \text{and} \quad c^b \times b^a \times a \xrightarrow{id \times \varepsilon} c^b \times b \to c
\]

the latter defined using the counit of the cartesian closure adjunction.

**Proof.** The task is to verify the commutative diagrams of (A.2.1) in \( \mathcal{V} \) and then observe that Lemma A.1.6 reveals that the underlying category of the \( \mathcal{V} \)-category defined by the statement is the 1-category \( \mathcal{V} \). We leave the identity conditions to the reader and verify associativity.

The definition of the composition map as an adjoint transpose implies that its adjoint transpose, the top-right composite below, is given by the left-bottom composite:

\[
c^b \times b^a \times a \xrightarrow{\circ \times \text{id}} c^a \times a
\]

\[
id \times \varepsilon \downarrow \quad \varepsilon \downarrow
\]

\[
c^b \times b \xrightarrow{\varepsilon} c
\]

The associativity diagram below-left commutes if and only if the transposed diagram appearing as the outer boundary composite below-right commutes:

\[
d^c \times c^b \times b^a \xrightarrow{\circ \times \text{id}} d^b \times b^a
\]

\[
\downarrow \text{id} \times \varepsilon \quad \downarrow \varepsilon
\]

\[
d^c \times c^a \xrightarrow{\circ} d^a
\]

\[
d^c \times c^b \times b \xrightarrow{\circ \times \text{id}} d^b \times b
\]

\[
\downarrow \text{id} \times \varepsilon \quad \downarrow \varepsilon
\]

\[
d^c \times c^a \times Aa \xrightarrow{id \times \varepsilon} d^c \times c \xrightarrow{\varepsilon} d
\]

which follows from bifunctoriality of \( \times \) and two instances of the commutative square above. \( \square \)

**A.2.4. Definition.** The **free \( \mathcal{V} \)-category** on a 1-category \( \mathcal{C} \) has

- the same objects as \( \mathcal{C} \)
- the hom-objects defined to be coproducts \( \coprod_{\mathcal{C}(x,y)} 1 \) of the terminal object \( 1 \in \mathcal{V} \) indexed by the hom-set \( \mathcal{C}(x,y) \)
- the identity map \( \text{id}_x \colon 1 \to \coprod_{\mathcal{C}(x,y)} 1 \) given by the inclusion of the component indexed by the identity arrow
- the composition map given by acting by the composition function on the indexing sets:

\[
\coprod_{\mathcal{C}(y,z)} 1 \times \coprod_{\mathcal{C}(x,y)} 1 \cong \coprod_{\mathcal{C}(y,z) \times \mathcal{C}(x,y)} 1 \xrightarrow{\prod 1} \coprod_{\mathcal{C}(x,z)} 1
\]

For example, free \( \text{Cat} \)-enriched categories are those with no non-identity 2-cells, while free \( \text{sSet} \)-enriched categories are those with no non-degenerate arrows in positive dimensions. When context allows, we use the same name for the 1-category \( \mathcal{C} \) and the free \( \mathcal{V} \)-category it generates, using language to disambiguate.

**A.2.5. Definition.** A **\( \mathcal{V} \)-enriched functor** or **\( \mathcal{V} \)-functor** \( F \colon \mathcal{C} \to \mathcal{D} \) is given by

- a mapping on objects that carries each \( x \in \mathcal{C} \) to some \( Fx \in \mathcal{D} \)
for each pair of objects \( x, y \in C \), an internal action on the \( \mathcal{V} \)-objects of arrows given by a morphism \( F_{x,y} : C(x, y) \to \mathcal{D}(Fx, Fy) \in \mathcal{V} \) so that the \( \mathcal{V} \)-functoriality diagrams commute:

\[
\begin{array}{ccc}
C(y, z) \times C(x, y) & \xrightarrow{C(z, y)} & C(x, z) \\
\downarrow F_{y,z} \times F_{x,y} & & \downarrow F_{x,z} \\
\mathcal{D}(Fy, Fz) \times \mathcal{D}(Fx, Fy) & \xrightarrow{C(z, y)} & \mathcal{D}(Fx, Fz) \\
\end{array}
\]

\[1 \xrightarrow{id} C(x, x) \]

\[\begin{array}{ccc}
\mathcal{D}(Fx, Fz) \times \mathcal{D}(Fx, Fy) & \xrightarrow{C(z, y)} & \mathcal{D}(Fx, Fy) \\
\downarrow id_{Fx} \times F_{x,y} & & \downarrow F_{x,z} \\
\mathcal{D}(Fx, Fx) & & \mathcal{D}(Fx, Fx)
\end{array}\]

A prototypical example is given by the representable functors:

A.2.6. Example. For any \( \mathcal{V} \)-category \( C \) and object \( c \in C \), the enriched representable \( \mathcal{V} \)-functor \( C(c, -) : C \to \mathcal{V} \) is defined on objects by the assignment \( x \in C \mapsto C(c, x) \in \mathcal{V} \) and whose internal action on arrows

\[C(x, y) \xrightarrow{C(c, -)_{x,y}} C(c, y) \cdot C(c, x) \leftrightarrow C(x, y) \times C(c, x) \xrightarrow{C(c, -)} C(c, y)\]

is given by the adjoint transpose of the internal composition map for \( C \). The \( \mathcal{V} \)-functoriality diagrams are transposes of associativity and identity diagrams in \( C \).

The contravariant enriched representable functors are defined similarly; see Exercise A.2.iii.

A.2.7. Remark. An enriched representable functor can be thought of as a “two-step” enrichment of the corresponding unenriched representable functor: the first step enriches the hom-sets to hom-objects in \( \mathcal{V} \) and the second step enriches the composition function to an internal composition map in \( \mathcal{V} \). To enriched a 1-category \( C \) to a \( \mathcal{V} \)-category with \( C \) as its underlying 1-category requires more than simply a lift of the hom bifunctor:

\[C^{\text{op}} \times C \xrightarrow{C(-,-)} \mathcal{V}\]

In addition, the \( \mathcal{V} \)-valued representable \( C(-, -) : C^{\text{op}} \times C \to \mathcal{V} \) must be a \( \mathcal{V} \)-bifunctor in the sense of Exercise A.2.iv, which tells us that the composition map may be defined internally to \( \mathcal{V} \) and the identity and associativity laws hold there.

Both of the constructions of underlying unenriched categories and free categories are functorial; see Exercise A.2.v. The relationship between these constructions is summarized by the following proposition, whose proof is left to Exercise A.2.vi, because it will be generalized by a result that we prove in §A.7.

A.2.8. Proposition. The free \( \mathcal{V} \)-category functor defines a fully faithful left adjoint to the underlying category functor. Consequently, a \( \mathcal{V} \)-category is free just when it is isomorphic to the free category on its underlying category via the counit of this adjunction.

Proof. Exercise A.2.vi or see Proposition A.7.6.

Exercises.

A.2.i. Exercise. Verify that the underlying category of an enriched category described in Definition A.2.2 is indeed a category.

A.2.ii. Exercise. Verify the unit condition left to the reader in the proof of Lemma A.2.3.
A.2.iii. Exercise. Define the opposite of a \( \mathcal{V} \)-category and dualize Example A.2.6 to define contravariant enriched representable functors.

A.2.iv. Exercise.

(i) Define the cartesian product of two \( \mathcal{V} \)-categories.

(ii) Define a multivariable \( \mathcal{V} \)-functor.

(iii) Use these notions to show that any \( \mathcal{V} \)-category \( \mathcal{C} \) comes equipped with a canonical \( \mathcal{V} \)-bifunctor \( \mathcal{C}(\cdot, \cdot) : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{V} \) that restricts to the co- and contravariant representable functors.

A.2.v. Exercise.

(i) Define the underlying functor of an enriched functor.

(ii) Prove that the passage from enriched functors to underlying unenriched functors is functorial.

(iii) Define the free enriched functor on an unenriched functor.

(iv) Prove the passage from unenriched functors to free enriched functors is functorial.

A.3. Enriched Natural Transformations and the Enriched Yoneda Lemma

Recall an (unenriched) natural transformation \( \alpha : F \Rightarrow G \) between parallel functors \( F, G : \mathcal{C} \to \mathcal{D} \) is given by:

- the data of an arrow \( \alpha_x \in \mathcal{D}(F_x, G_x) \) for each \( x \in \mathcal{C} \)
- subject to the condition that for each morphism \( f \in \mathcal{C}(x, y) \), the diagram

\[
\begin{array}{ccc}
F_x & \xrightarrow{\alpha_x} & G_x \\
F f & \downarrow & \downarrow G f \\
F y & \xrightarrow{\alpha_y} & G y
\end{array}
\]  

(A.3.1)

This enriches to the notion of a \( \mathcal{V} \)-natural transformation whose data is exactly the same — a family of arrows in the underlying category of \( \mathcal{D} \) indexed by the objects of \( \mathcal{C} \) — but with a stronger \( \mathcal{V} \)-naturality condition expressed by internalizing the naturality condition (A.3.1).

A.3.2. Definition. A \( \mathcal{V} \)-enriched natural transformation of \( \mathcal{V} \)-natural transformation \( \alpha : F \Rightarrow G \) between \( \mathcal{V} \)-enriched functors \( F, G : \mathcal{C} \to \mathcal{D} \) is given by:

- an arrow \( \alpha_x : 1 \to \mathcal{D}(F_x, G_x) \) for each \( x \in \mathcal{C} \)
- so that for each pair of objects \( x, y \in \mathcal{C} \), the following \( \mathcal{V} \)-naturality square commutes in \( \mathcal{V} \):

\[
\begin{array}{ccc}
\mathcal{C}(x, y) & \xrightarrow{\alpha_y \times \alpha_x} & \mathcal{D}(F_y, G_y) \times \mathcal{D}(F_x, F_y) \\
G_{x,y} \times \alpha_x & \downarrow & \downarrow \circ \\
\mathcal{D}(G_x, G_y) \times \mathcal{D}(F_x, G_x) & \xrightarrow{o} & \mathcal{D}(F_x, G_y)
\end{array}
\]  

(A.3.3)

A.3.4. Example. An arrow \( f : 1 \to \mathcal{C}(x, y) \) in the underlying category of a \( \mathcal{V} \)-category \( \mathcal{C} \) defines a \( \mathcal{V} \)-natural transformation \( f^* : \mathcal{C}(y, \cdot) \Rightarrow \mathcal{C}(x, \cdot) \) between the enriched representable functors whose component at \( z \in \mathcal{C} \) is defined by evaluating the adjoint transpose of the composition map at \( f \):

\[
1 \xrightarrow{f} \mathcal{C}(x, y) \xrightarrow{C(\cdot, z)_{xy}} \mathcal{C}(x, z)^{C(y, z)}
\]
The required $\mathcal{V}$-naturality square arises by evaluating one component of the associativity diagram for $\mathcal{C}$ at $f$.

$\mathcal{V}$-natural transformations compose as unenriched natural transformations do:

A.3.5. Lemma.

(i) The vertical composite of $\mathcal{V}$-natural transformations $\alpha : F \Rightarrow G$ and $\beta : G \Rightarrow H$, both from $\mathcal{C}$ to $\mathcal{D}$ has component $(\beta \cdot \alpha)_x$ at $x \in \mathcal{C}$ defined by the composite

$$1 \xrightarrow{\beta_x \times \alpha_x} \mathcal{D}(Gx, Hx) \times \mathcal{D}(Fx, Gx) \xrightarrow{\circ} \mathcal{D}(Fx, Hx)$$

(ii) The horizontal composite of $\alpha : F \Rightarrow G$ from $\mathcal{C}$ to $\mathcal{D}$ and $\gamma : H \Rightarrow K$ from $\mathcal{D}$ to $\mathcal{E}$ has component $(\gamma \ast \alpha)_x$ at $x \in \mathcal{C}$ defined by the common composite

$$1 \xrightarrow{\alpha_x} \mathcal{D}(Fx, Gx) \xrightarrow{\gamma_{Gx} \times H_{Fx}, Gx} \mathcal{E}(K Gx, H Gx) \times \mathcal{E}(H Fx, H Gx)$$

$$\xrightarrow{\circ} \mathcal{E}(K Fx, K Gx) \times \mathcal{E}(H Fx, K Fx) \xrightarrow{\circ} \mathcal{D}(H Fx, K Gx)$$

which is well-defined by $\mathcal{V}$-naturality of $\gamma$.

Proof. Exercise A.3.i. \qed

The data of the underlying natural transformation of a $\mathcal{V}$-natural transformation is given by the same family of arrows. The unenriched naturality condition (A.3.1) is proven by evaluating the enriched naturality condition (A.3.3) at an underlying arrow $f : 1 \rightarrow \mathcal{C}(x, y)$. In particular, the middle four interchange rule\(^7\) for horizontal and vertical composition of $\mathcal{V}$-natural transformations follows from the middle four interchange rule for horizontal and vertical composition of unenriched natural transformations for the data of the latter determines the data of the former. Consequently, Lemma A.3.5 implies that:

A.3.6. Corollary. For any cartesian closed category $\mathcal{V}$, there is a 2-category $\mathcal{V}$-$\text{Cat}$ of $\mathcal{V}$-categories, $\mathcal{V}$-functors, and $\mathcal{V}$-natural transformations. Moreover, the underlying category functor $\mathcal{V}$-$\text{Cat} \rightarrow \text{Cat}$ and the free $\mathcal{V}$-category functor $\text{Cat} \rightarrow \mathcal{V}$-$\text{Cat}$ are both 2-functors. \qed

We now turn our attention to the $\mathcal{V}$-enriched Yoneda lemma, which we present in several forms. One role of the Yoneda lemma is to give a representable characterization of isomorphic objects in $\mathcal{C}$. When $\mathcal{C}$ is a $\mathcal{V}$-category, this has several forms involving each of the three notions of “representable” functor appearing in Proposition ???. The notion of $\mathcal{V}$-natural isomorphism referred to in the following result is defined to be a $\mathcal{V}$-natural transformation $\alpha : F \Rightarrow G$ with an inverse $\alpha^{-1} : G \Rightarrow F$ for vertical composition.

A.3.7. Lemma. For objects $x, y$ in a $\mathcal{V}$-category $\mathcal{C}$ the following are equivalent:

(i) $x$ and $y$ are isomorphic as objects of the underlying category of $\mathcal{C}$.

(ii) The $\text{Set}$-valued unenriched representable functors $\mathcal{C}(x, -)_0, \mathcal{C}(y, -)_0 : \mathcal{C} \rightarrow \text{Set}$ are naturally isomorphic.

(iii) The $\mathcal{V}$-valued unenriched representable functors $\mathcal{C}(x, -), \mathcal{C}(y, -) : \mathcal{C} \rightarrow \mathcal{V}$ are naturally isomorphic.

(iv) The $\mathcal{V}$-valued $\mathcal{V}$-functors $\mathcal{C}(x, -), \mathcal{C}(y, -) : \mathcal{C} \rightarrow \mathcal{V}$ are $\mathcal{V}$-naturally isomorphic.

\(^7\)See Definition B.1.1 for a description of middle four interchange in a 2-category.
Proof. Applying the underlying category 2-functor \( (-)_0 : \mathcal{V}\text{-Cat} \to \text{Cat} \), the fourth statement implies the third. The third statement implies the second by whiskering with the underlying set functor \( (-)_0 : \mathcal{V} \to \text{Set} \). The second statement implies the first by the unenriched Yoneda lemma; this is still the main point. Finally, the first statement implies the last by a direct construction: if \( f : 1 \to \mathcal{C}(x, y) \) and \( g : 1 \to \mathcal{C}(y, x) \) define an isomorphism in the underlying category of \( \mathcal{C} \), the corresponding representable \( \mathcal{V} \)-natural transformations of Example A.3.4 define a \( \mathcal{V} \)-natural isomorphism. □

Lemma A.3.7 defines a common notion of isomorphism between two objects of an enriched category, which turns out to be no different the usual unenriched notion of isomorphism. This can be thought of as defining a “cheap” form of the enriched Yoneda lemma. The full form of the \( \mathcal{V} \)-Yoneda lemma enriches the usual statement — a natural isomorphism between the set of natural transformations whose domain is a representable functor to the set defined by evaluating the codomain at the representing object — to an isomorphism in \( \mathcal{V} \). The first step to make this precise is to enrich the set of \( \mathcal{V} \)-natural transformations between a parallel pair of \( \mathcal{V} \)-functors can to define an object of \( \mathcal{V} \).

A.3.8. Definition. Let \( \mathcal{V} \) be a complete cartesian closed category and consider a parallel pair of \( \mathcal{V} \)-functors \( F, G : \mathcal{C} \to \mathcal{D} \), with \( \mathcal{C} \) a small \( \mathcal{V} \)-category. Then the \( \mathcal{V} \)-object of \( \mathcal{V} \)-natural transformations is defined by the equalizer diagram

\[
\mathcal{D}^\mathcal{C}(F, G) \rightrightarrows \prod_{z \in \mathcal{C}} \mathcal{D}(Fz, Gz) \rightrightarrows \prod_{x, y \in \mathcal{C}} \mathcal{D}(Fx, Gy)^{\mathcal{C}(x, y)}
\]

where one map in the equalizer diagram is defined by projecting to \( \mathcal{D}(Fx, Gx) \), applying the internal action of \( G \) on arrows, and then composing, while the other is defined by projecting to \( \mathcal{D}(Fy, Gy) \), applying the internal action of \( F \) on arrows, and then composing:

\[
\begin{align*}
\prod_{z \in \mathcal{C}} \mathcal{D}(Fz, Gz) & \xrightarrow{\pi} \mathcal{D}(Fx, Gx) & \xrightarrow{\pi} \mathcal{D}(Fy, Gy)
\end{align*}
\]

\[
\begin{align*}
\mathcal{D}(Fx, Gx)^{\mathcal{C}(x, y)} & \xrightarrow{\mathcal{D}(Fy, Gy)^{\mathcal{D}(Fx, Fy)}} \mathcal{D}(Fy, Gy)^{\mathcal{D}(Gx, Gy)}
\end{align*}
\]

A.3.9. Lemma. The underlying set of the \( \mathcal{V} \)-object of \( \mathcal{V} \)-natural transformations \( \mathcal{V}^\mathcal{C}(F, G) \) is the set of \( \mathcal{V} \)-natural transformations from \( F \) to \( G \).

Proof. By its defining universal property, elements of the underlying set of \( \mathcal{V}^\mathcal{C}(F, G) \) correspond to maps \( \alpha : 1 \to \prod_{z \in \mathcal{C}} \mathcal{V}(Fz, Gz) \) that equalize the parallel pair of maps described in Definition A.3.8. The map \( \alpha \) defines the components of a \( \mathcal{V} \)-natural transformation \( \alpha : F \Rightarrow G \) and the commutativity condition transposes to (A.3.3). □

The Yoneda lemma can be expressed by the slogan “evaluation at the identity is an isomorphism,” but since in the enriched context the enriched object of natural transformations is defined via a limit, it is easier to define the map that induces a natural transformation instead. Given an object \( a \in \mathcal{A} \) in a small \( \mathcal{V} \)-category \( \mathcal{A} \) and a \( \mathcal{V} \)-functor \( F : \mathcal{A} \to \mathcal{V} \), the internal action of \( F \) on arrows transposes to define a map that equals the parallel pair

\[
Fa \xrightarrow{F_a} \prod_{z \in \mathcal{A}} Fz^{\mathcal{A}(a, z)} \xrightarrow{\prod_{x, y \in \mathcal{A}} Fy^{\mathcal{A}(a, x) \times \mathcal{A}(x, y)}}
\]

and thus induces a map \( Fa \to \mathcal{V}^\mathcal{A}(\mathcal{A}(a, -), F) \) in \( \mathcal{V} \).
Theorem (enriched Yoneda lemma). For any small \( \mathcal{V} \)-category \( \mathcal{A} \), object \( a \in \mathcal{A} \), and \( \mathcal{V} \)-functor \( F : \mathcal{A} \to \mathcal{V} \), the canonical map defines an isomorphism in \( \mathcal{V} \)

\[
F a \cong \mathcal{V}^\mathcal{A}(\mathcal{A}(a, -), F)
\]

that is \( \mathcal{V} \)-natural in both \( a \) and \( F \).

Proof. To prove the isomorphism, it suffices to verify that (A.3.10) is a limit cone. To that end consider another cone over the parallel pair

\[
\mathcal{V} \to \prod_{z \in \mathcal{A}} \mathcal{V}(a, z) \to \prod_{x, y \in \mathcal{A}} \mathcal{V}(a, x) \times \mathcal{V}(x, y)
\]

and define a candidate factorization by evaluating the transpose of the component \( \lambda_a \) at \( \text{id}_a \):

\[
\lambda_a(\text{id}_a) := \mathcal{V} \to \mathcal{V}(a, a) \times \mathcal{V} \to \mathcal{V}(a) \to Fa
\]

To see that \( \lambda_a(\text{id}_a) : \mathcal{V} \to Fa \) indeed defines a factorization of \( \lambda \) through the limit cone, it suffices to show commutativity at each component \( \mathcal{V}(a, z) \) of the product, which we verify in transposed form:

\[
\begin{array}{ccc}
\mathcal{V}(a, z) \times \mathcal{V} & \xrightarrow{\lambda} & \mathcal{V}(a, a) \times \mathcal{V} \\
\mathcal{V}(a, z) \times \lambda_a & \downarrow & \mathcal{V}(a, z) \times \lambda_z \\
\mathcal{V}(a, z) \times Fa & \xrightarrow{\lambda_z} & \mathcal{V}(a, z) \times Fa & \xrightarrow{\lambda_z} & \mathcal{V}(a, z) \times Fa
\end{array}
\]

The upper triangle commutes by the identity law for \( \mathcal{A} \) while the bottom square commutes because \( \lambda \) defines a cone over the parallel pair. Uniqueness of the factorization \( \lambda_a(\text{id}_a) \) follows from the same diagram by taking \( z = a \) and evaluating at \( \text{id}_a \).

The verification of the \( \mathcal{V} \)-naturality of the isomorphism \( Fa \cong \mathcal{V}^\mathcal{A}(\mathcal{A}(a, -), F) \) is left to the reader or to [67, §2.4]. \( \Box \)

Passing to underlying sets:

Corollary. For any small \( \mathcal{V} \)-category \( \mathcal{A} \), object \( a \in \mathcal{A} \), and \( \mathcal{V} \)-functor \( F : \mathcal{A} \to \mathcal{V} \), there is a bijection between \( \mathcal{V} \)-natural transformations \( \alpha : \mathcal{A}(a, -) \Rightarrow F \) and elements \( 1 \to Fa \) in the underlying set of \( Fa \) implemented by evaluating the component at \( a \in \mathcal{A} \) at the identity \( \text{id}_a \).

This gives a criterion for establishing the representability of a \( \mathcal{V} \)-functor by presenting the minimal data required to establish the defining \( \mathcal{V} \)-natural isomorphism.

Corollary. For a \( \mathcal{V} \)-functor \( F : \mathcal{A}^{\text{op}} \to \mathcal{V} \) and an object \( a \in \mathcal{A} \) the following are equivalent and define what it means for \( a \) to represent \( F 

(i) There exists an isomorphism

\[
\mathcal{A}(x, a) \cong F x
\]

in \( \mathcal{V} \) that is \( \mathcal{V} \)-natural in \( x \in \mathcal{A} \).
(ii) There exists an element \( u : 1 \to Fa \) in the underlying set of \( Fa \) so that the composite map

\[
\mathcal{A}(x,a) \xrightarrow{F_{x,a}} \mathcal{V}(Fa,Fx) \xrightarrow{-\circ u} \mathcal{V}(1,Fx) \cong Fx
\]
defines an isomorphism in \( \mathcal{V} \) for all \( x \in \mathcal{A} \).

**Proof.** By Corollary A.3.12 the element \( u : 1 \to Fa \) in the underlying set of \( Fa \) determines a unique \( \mathcal{V} \)-natural transformation \( \mathcal{A}(\_ ,a) \Rightarrow F \) whose component at \( x \in \mathcal{A} \) is the map of the statement. Thus, the universal element \( u \) defines a \( \mathcal{V} \)-natural isomorphism and not just a \( \mathcal{V} \)-natural transformation just when the map of the statement is an isomorphism. \( \square \)

Since we have assumed our bases for enrichment to be cartesian closed, the 2-category \( \mathcal{V}\text{-}\mathsf{Cat} \) admits finite products, allowing us to define multivariable \( \mathcal{V} \)-functors; see Exercise A.2.iv. The following result will imply that the structures characterized by \( \mathcal{V} \)-natural isomorphisms in §A.4 and §A.5 assemble into \( \mathcal{V} \)-functors.

**A.3.14. Proposition.** Let \( M : \mathcal{B}^{\text{op}} \times \mathcal{A} \to \mathcal{V} \) be a \( \mathcal{V} \)-functor so that for each \( a \in \mathcal{A} \), the \( \mathcal{V} \)-functor \( M(\_ ,a) : \mathcal{B}^{\text{op}} \to \mathcal{V} \) is represented by some \( Fa \in \mathcal{B} \), meaning there exists a \( \mathcal{V} \)-natural isomorphism \( \mathcal{B}(b,Fa) \cong M(b,a) \).

Then there is a unique way of extending the mapping \( a \in \mathcal{A} \mapsto Fa \in \mathcal{B} \) to a \( \mathcal{V} \)-functor \( F : \mathcal{A} \to \mathcal{B} \) so that the isomorphisms are \( \mathcal{V} \)-natural in \( a \in \mathcal{A} \) as well as \( b \in \mathcal{B} \).

**Proof.** By the Yoneda lemma in the form of Corollary A.3.12, to define a family of isomorphisms \( \alpha_{b,a} : \mathcal{B}(b,Fa) \cong M(b,a) \) for each \( a \in \mathcal{A} \) that are \( \mathcal{V} \)-natural in \( b \in \mathcal{B} \) is to define a family of elements \( \eta_a : 1 \to M(Fa,a) \) for each \( a \in \mathcal{A} \) that satisfy the condition of Corollary A.3.13(ii). By the \( \mathcal{V} \)-naturality statement in the Yoneda lemma, for the isomorphism \( \alpha_{b,a} \) to be \( \mathcal{V} \)-natural in \( a \) is equivalent to the family of elements \( \eta_a : 1 \to M(Fa,a) \) being “extraordinarily” \( \mathcal{V} \)-natural in \( a \). What this means is that for any pair of objects \( a,a' \in \mathcal{A} \), the outer square commutes:

As exhibited by the top triangle, the definition of the top-horizontal map \( M(F_{-,a})_{a,a'} \) depends on the internal action of \( F \) on arrows, which we seek to define, but note that the composite of the other factor with the right vertical map is the natural isomorphism \( \alpha_{F_{a'}a} \), as exhibited by the right triangle. Thus, there is a unique way to define \( F_{a' a} \) making the extraordinary \( \mathcal{V} \)-naturality square commute, namely, by ensuring that the lower left quadrilateral commutes, which is exactly the claim. \( \mathcal{V} \)-functoriality of these internal action maps for \( F \) follows from \( \mathcal{V} \)-functoriality of \( M \) in the \( \mathcal{A} \) variable. \( \square \)

We close this section with some applications of the enriched Yoneda lemma. The correct notions of \( \mathcal{V} \)-enriched equivalence or \( \mathcal{V} \)-enriched adjunction are given by interpreting the standard 2-categorical notions of equivalence and adjunction in the 2-category \( \mathcal{V}\text{-}\mathsf{Cat} \). For sake of contrast, we present both
notions in an alternate form here and leave it to the reader to apply Theorem A.3.11 to relate these to the 2-categorical notions.

A.3.15. Definition. A pair of \( \mathcal{V} \)-categories \( \mathcal{C} \) and \( \mathcal{D} \) are \( \mathcal{V} \)-equivalent if there exists a \( \mathcal{V} \)-functor \( F: \mathcal{C} \to \mathcal{D} \) that is

- \( \mathcal{V} \)-fully faithful: i.e., each \( F_{x,y}: \mathcal{C}(x,y) \to \mathcal{D}(Fx,Fy) \) is an isomorphism in \( \mathcal{V} \) and
- essentially surjective on objects: i.e., each \( d \in \mathcal{D} \) is isomorphic to \( Fc \) for some \( c \in \mathcal{C} \).

A.3.16. Definition. A \( \mathcal{V} \)-adjunction is given by a pair of \( \mathcal{V} \)-functors \( F: \mathcal{B} \to \mathcal{A} \) and \( U: \mathcal{A} \to \mathcal{B} \) together with isomorphisms

\[ \mathcal{A}(Fb,a) \cong \mathcal{B}(b,Ua) \]

that are \( \mathcal{V} \)-natural in both \( a \in \mathcal{A} \) and \( b \in \mathcal{B} \).

A.3.17. Remark. By Proposition A.3.14, a \( \mathcal{V} \)-functor \( U: \mathcal{A} \to \mathcal{B} \) admits a \( \mathcal{V} \)-left adjoint if and only if each \( \mathcal{B}(b,U-) \): \( \mathcal{A} \to \mathcal{V} \) is represented by some object \( Fb \in \mathcal{A} \), in which case the data of the \( \mathcal{V} \)-natural isomorphism \( \mathcal{A}(Fb,-) \cong \mathcal{B}(b,-) \) equips \( b \in \mathcal{B} \mapsto Fb \in \mathcal{A} \) with the structure of a \( \mathcal{V} \)-functor. Dual remarks construct enriched right adjoints to a given \( \mathcal{V} \)-functor.

Exercises.

A.3.ii. Exercise. Suppose \( F: \mathcal{C} \to \mathcal{D} \) is a \( \mathcal{V} \)-functor. Prove that the map

\[ C(x,y) \xrightarrow{F_{x,y}} \mathcal{D}(Fx,Fy) \]

is \( \mathcal{V} \)-natural in both \( x \) and \( y \).

A.3.iii. Exercise. When \( \mathcal{V} \) is complete, show for any pair of \( \mathcal{V} \)-categories \( \mathcal{C} \) and \( \mathcal{D} \), with \( \mathcal{C} \) small, that Definition A.3.8 makes \( \mathcal{D}^\mathcal{C} \) into a \( \mathcal{V} \)-category.

A.3.iv. Exercise. Verify the \( \mathcal{V} \)-naturality statement in Theorem A.3.11.

A.3.v. Exercise. Use Corollary A.3.12 to show that the notions of \( \mathcal{V} \)-equivalence and \( \mathcal{V} \)-adjunction given in Definitions A.3.15 and A.3.16 are equivalent to the 2-categorical notions in \( \mathcal{V}\text{-Cat} \).

A.4. Tensors and Cotensors

A \( \mathcal{V} \)-category \( \mathcal{C} \) admits tensors just when for all \( c \in \mathcal{C} \), the covariant representable functor \( \mathcal{C}(c,-) : \mathcal{C} \to \mathcal{V} \) admits a left \( \mathcal{V} \)-adjoint \( - \otimes c : \mathcal{V} \to \mathcal{C} \). Dually, a \( \mathcal{V} \)-category \( \mathcal{C} \) admits cotensors just when the contravariant representable functor \( \mathcal{C}(-,c) : \mathcal{C}^{\text{op}} \to \mathcal{V} \) admits a mutual right \( \mathcal{V} \)-adjoint \( c^- : \mathcal{V}^{\text{op}} \to \mathcal{C} \). The aim in this section is to introduce both constructions formally. As we shall discover, the presence of tensors or cotensors is useful when enriching functors between the categories that underly enriched categories.

A.4.1. Definition. A \( \mathcal{V} \)-category \( \mathcal{C} \) is cotensored, if for all \( v \in \mathcal{V} \) and \( c \in \mathcal{C} \), the \( \mathcal{V} \)-functor \( \mathcal{C}(-,c)^v : \mathcal{C}^{\text{op}} \to \mathcal{V} \) is represented by an object \( c^v \in \mathcal{C} \), i.e., there exists an isomorphism

\[ C(x,c^v) \cong C(x,c)^v \]

in \( \mathcal{V} \) that is \( \mathcal{V} \)-natural in \( x \). By Proposition A.3.14, the cotensor product defines a unique \( \mathcal{V} \)-functor

\[ C \times \mathcal{V}^{\text{op}} \xrightarrow{(-)^-} \mathcal{C} \]

making the defining isomorphism \( \mathcal{V} \)-natural in all three variables.
A.4.2. Definition. Dually, a \( \mathcal{V} \)-category \( \mathcal{C} \) is \textit{tensored} if for all \( v \in \mathcal{V} \) and \( c \in \mathcal{C} \) the \( \mathcal{V} \)-functor \( C(c, -)^v : \mathcal{C} \to \mathcal{V} \) is represented by an object \( v \otimes c \in \mathcal{C} \), i.e., there exists an isomorphism
\[
C(v \otimes c, x) \cong C(c, x)^v
\]
in \( \mathcal{V} \) that is \( \mathcal{V} \)-natural in \( x \). By Proposition A.3.14, the tensor product defines a unique \( \mathcal{V} \)-functor
\[
\mathcal{V} \times \mathcal{C} \to \mathcal{C}
\]
making the defining isomorphism \( \mathcal{V} \)-natural in all three variables.

Immediately from these definitions:

A.4.3. Lemma. A \( \mathcal{V} \)-category \( \mathcal{C} \) is tensored and cotensored if and only if the \( \mathcal{V} \)-functor \( C(-, -) : \mathcal{C}^{\op} \times \mathcal{C} \to \mathcal{V} \) is part of a two-variable \( \mathcal{V} \)-adjunction
\[
C(v \times a, b) \cong C(a, b)^v
\]
as expressed by the commutative triangle of \( \mathcal{V} \)-natural isomorphisms.

The fact that the natural isomorphisms defining tensors and cotensors are required to exist \( \mathcal{V} \)-naturally in \( \mathcal{V} \) has the following consequence:

A.4.4. Lemma. In any category \( \mathcal{C} \) that is enriched and cotensored over \( \mathcal{V} \), there are \( \mathcal{V} \)-natural isomorphisms
\[
c^1 \cong c \quad \text{and} \quad (c^u)^v \cong (c^v)^u
\]
for \( u, v \in \mathcal{V} \) and \( c \in \mathcal{C} \).

Dually if \( \mathcal{C} \) is enriched and tensored over \( \mathcal{V} \), there are \( \mathcal{V} \)-natural isomorphisms
\[
1 \otimes c \cong c \quad \text{and} \quad (u \times v) \otimes c \cong u \otimes (v \otimes c)
\]
for \( u, v \in \mathcal{V} \) and \( c \in \mathcal{C} \).

Note further that there are various coherence relations between these \( \mathcal{V} \)-natural isomorphisms that derive from the coherences of the cartesian closed category \( \mathcal{V} \).

Proof. By Lemma A.3.7, to define the displayed isomorphisms, it suffices to prove that these objects represent the same \( \mathcal{V} \)-functors \( \mathcal{C}^{\op} \to \mathcal{V} \). By the defining universal property of the cotensor, for any \( x \in \mathcal{C} \),
\[
C(x, c^1) \cong C(x, c) \cong C(x, c)
\]
the last isomorphism by Remark A.1.9. Since these isomorphisms are \( \mathcal{V} \)-natural in \( c \) as well as \( x \), the isomorphism \( c^1 \cong c \) is \( \mathcal{V} \)-natural as well.

Similarly, by the defining universal property of the cotensor, we have \( \mathcal{V} \)-natural isomorphisms in each of the three vertices of the triangle below
\[
C(x, c^{u,v}) \cong C(x, c^{v,u}) \cong (C(x, c)^u)^v \cong C(x, (c^u)^v)
\]
whence the connecting \( \mathcal{V} \)-natural isomorphisms are given by Lemma A.1.7. Again the \( \mathcal{V} \)-naturality of these isomorphisms in \( u, v \), and \( c \) gives the \( \mathcal{V} \)-naturality of the statement. \( \square \)

Extending Lemma A.2.3:

A.4.5. Lemma. A cartesian closed category \((\mathcal{V}, \times, 1)\) is enriched, tensored, and cotensored over itself, with tensors defined by the cartesian product and cotensors defined by the internal hom:\(^8\)

\[ v \otimes w := v \times w \quad \text{and} \quad w^v := w^v. \]

Proof. Lemma A.1.7 establishes the required isomorphisms (A.1.8) in \( \mathcal{V} \). The proof of their \( \mathcal{V} \)-naturality is left to the reader or to [67, §1.8]. \( \square \)

Now consider a \( \mathcal{V} \)-functor \( F : \mathcal{C} \rightarrow \mathcal{D} \). If \( \mathcal{C} \) and \( \mathcal{D} \) are tensored over \( \mathcal{V} \), then the composite map

\[ v \xrightarrow{\eta_v} C(c, v \otimes c) \xrightarrow{F, \text{left}} D(Fc, F(v \otimes c)) \]

transposes to define a canonical \( \mathcal{V} \)-natural transformation \( \tau_{v, c} : v \otimes Fc \rightarrow F(v \otimes c) \). The \( \mathcal{V} \)-functor \( F \) preserves tensors if this map is an isomorphism in \( \mathcal{D} \).

The presence of tensors and cotensors provides a convenient mechanism for testing whether an a priori unenriched adjunction may be enriched to a \( \mathcal{V} \)-adjunction.

A.4.6. Proposition. Suppose \( \mathcal{A} \) and \( \mathcal{B} \) are \( \mathcal{V} \)-categories.

(i) If \( \mathcal{A} \) and \( \mathcal{B} \) are tensored over \( \mathcal{V} \) then a \( \mathcal{V} \)-functor \( F : \mathcal{B} \rightarrow \mathcal{A} \) is a left \( \mathcal{V} \)-adjoint if and only if \( F \) admits an unenriched right adjoint and preserves tensors.

(ii) If \( \mathcal{A} \) and \( \mathcal{B} \) are cotensored over \( \mathcal{V} \) then a \( \mathcal{V} \)-functor \( U : \mathcal{A} \rightarrow \mathcal{B} \) is a right \( \mathcal{V} \)-adjoint if and only if \( U \) admits an unenriched left adjoint and preserves cotensors.

Proof. We prove the sufficiency of the conditions in the first of the dual pair of statements and leave their necessity to Exercise A.4.1. Suppose \( F \) admits an unenriched right adjoint \( U \) with counit \( \varepsilon \).

By Example A.3.4 and Exercise A.3.ii, the composite map of hom-objects in \( \mathcal{V} \)

\[ \mathcal{B}(b, Ua) \xrightarrow{F_{b, Ua}} \mathcal{A}(Fb, F(Ua)) \xrightarrow{\varepsilon_{F(Ua)}} \mathcal{A}(Fb, a) \] (A.4.7)

which lifts the hom-set bijection of the unenriched adjunction, is \( \mathcal{V} \)-natural in \( b \). Our task is to show that (A.4.7) is an isomorphism in \( \mathcal{V} \). Then by Proposition A.3.14, there will be a unique way to enrich the right adjoint \( U \) so that this map is \( \mathcal{V} \)-natural in \( a \) as well as \( b \).

We claim that after applying the unenriched representable functor \( \mathcal{V}(v, -)_0 : \mathcal{V} \rightarrow \text{Set} \), this map fits into a commutative diagram

\[
\begin{array}{ccc}
\mathcal{V}(v, \mathcal{B}(b, Ua))_0 & \xrightarrow{F_{b, Ua}\ast} & \mathcal{V}(v, \mathcal{A}(Fb, F(Ua)))_0 & \xrightarrow{(\varepsilon_{F(Ua)})\ast} & \mathcal{V}(v, \mathcal{A}(Fb, a))_0 \\
\equiv & & \equiv & & \\
\mathcal{B}(v \otimes b, Ua)_{0} & \xrightarrow{\cong} & \mathcal{A}(F(v \otimes b), a)_{0} & \xrightarrow{\ast - \tau_{v, b}} & \mathcal{A}(v \otimes Fb, a)_{0}
\end{array}
\]

where the three isomorphisms are defined by transposing across the unenriched adjunctions. Since this is a diagram of functions between sets, to verify its commutativity, it suffices to consider an element \( f : v \rightarrow \mathcal{B}(b, Ua) \); the image under both composites is the composite map

\[ v \otimes Fb \xrightarrow{f \otimes Fb} B(b, Ua) \otimes Fb \xrightarrow{F_{b, Ua} \otimes Fb} A(Fb, F(Ua)) \otimes Fb \xrightarrow{ev} F(Ua) \xrightarrow{\varepsilon_{a}} a \]

\( ^8\)This excuses the abuse of exponential notation for both internal homs and cotensors.

439
in the underlying category of \( \mathcal{A} \). Since \( F \) preserves tensors, the map \( \tau_{v,b} \) is an isomorphism, and thus, by the unenriched Yoneda lemma, \((\text{A.4.7})\) is an isomorphism as well. \qed

**Exercises.**

A.4.i. **Exercise.** Prove that enriched left adjoints preserve tensors and define unenriched left adjoints.

A.4.ii. **Exercise.** Let \( \mathcal{J} \) be a small unenriched category and let \( \mathcal{C} \) be a \( \mathcal{V} \)-category. Prove that if \( \mathcal{C} \) is tensored or cotensored then so is \( \mathcal{C}^\mathcal{J} \).

**A.5. Conical Limits and Colimits**

Consider a diagram \( F: \mathcal{J} \to \mathcal{C} \) indexed by a 1-category and valued in a \( \mathcal{V} \)-category. A cone \( \lambda \) over the diagram \( F \) with summit suggestively denoted \( \lim F \in \mathcal{C} \) is a limit cone if composition with \( \lambda \) induces a natural bijection of hom-sets

\[
C(x, \ell)_0 \overset{\lambda_*}{\cong} \lim_{j \in \mathcal{J}} C(x, F_j)_0
\]

for all \( x \in \mathcal{C} \). If \( \mathcal{V} \) admits \( \mathcal{J} \)-shaped limits, then both the domain and codomain of this map lift to \( \mathcal{V} \), and it is natural to assert a stronger version of the usual universal property of a limit cone, demanding that composition with \( \lambda \) induces an isomorphism of \( \mathcal{V} \)-objects and not just of hom-sets. This gives the notion of a **conical limit** of a diagram valued in an enriched category. **Conical colimits** are defined dually.

The underlying set functor \((-)_0 : \mathcal{V} \to \text{Set} \) preserves limits and carries isomorphisms in \( \mathcal{V} \) to bijections between sets. Thus, conical limits necessarily define 1-categorical limits, so we pay particular attention to what is required to enrich a 1-categorical limit to a conical limit. The next lemma reveals that limits and colimits of diagrams valued in \( \mathcal{V} \) always enrich to define conical limits and conical colimits.

**A.5.1. Lemma.** If \( \mathcal{V} \) is a cartesian closed category, then any 1-categorical limit cone \( \lambda : \Delta \lim F \Rightarrow F \) over a diagram \( F: \mathcal{J} \to \mathcal{V} \) gives rise to an isomorphism in \( \mathcal{V} \)

\[
(\lim_{j \in \mathcal{J}} F_j)_v \cong \lim_{j \in \mathcal{J}} C(x, F_j)_0
\]

that is \( \mathcal{V} \)-natural in \( v \in \mathcal{V} \). Dually, any 1-categorical colimit cone \( \gamma : F \Rightarrow \Delta \text{colim} F \) gives rise to an isomorphism in \( \mathcal{V} \)

\[
\gamma^\text{colim}_j \cong \lim_{j \in \mathcal{J}^{\text{op}}} \mathcal{V}_j
\]

that is \( \mathcal{V} \)-natural in \( v \in \mathcal{V} \).

**Proof.** For any \( v \in \mathcal{V} \), the exponential \((-)^v : \mathcal{V} \to \mathcal{V} \) is right adjoint to the product functor \( - \times v : \mathcal{V} \to \mathcal{V} \); as such it preserves limits, giving rise to the isomorphism of the statement, while \( v^\text{v} : \mathcal{V}^{\text{op}} \to \mathcal{V} \), as a mutual right adjoint, carries colimits to limits. \qed

In terminology we now introduce, Lemma A.5.1 asserts that all 1-categorical limits and colimits in a cartesian closed category \( \mathcal{V} \) automatically enriched to define **conical limits** or **conical colimits**. For the remainder of this section, suppose that \( \mathcal{V} \) is a complete cartesian closed category, so that the limits in \( \mathcal{V} \) that encode the universal properties of conical limits and colimits are assumed to exist.
A.5.2. Definition. Let \( \mathcal{C} \) be a \( \mathcal{V} \)-category and let \( \mathcal{J} \) be a small 1-category. The **conical limit** of an unenriched diagram \( F : \mathcal{J} \to \mathcal{C} \) is given by an object \( \ell \in \mathcal{C} \) and a cone \( \lambda : \Delta \ell \Rightarrow F \) inducing a \( \mathcal{V} \)-natural isomorphism of hom-objects in \( \mathcal{V} \)

\[
C(x, \ell) \xrightarrow{\lambda^*_x} \lim_{j \in \mathcal{J}} C(x, F_j) \quad \in \quad \mathcal{V}
\]

for all \( x \in \mathcal{C} \). Dually, the **conical colimit** is given by an object \( c \in \mathcal{C} \) and a cone \( \gamma : F \Rightarrow \Delta c \) inducing a \( \mathcal{V} \)-natural isomorphism

\[
C(c, x) \xrightarrow{\gamma^*_x} \lim_{j \in \mathcal{J}^{\text{op}}} C(F_j, x) \quad \in \quad \mathcal{V}
\]

for all \( x \in \mathcal{C} \).

The isomorphism (A.5.3) looks identical to the usual isomorphism that characterizes 1-categorical limits except for one very important difference: it postulates an isomorphism in \( \mathcal{V} \) rather than an isomorphism in \( \mathbf{Set} \). In the case where \( \mathcal{V} = \mathbf{sSet} \), the isomorphism of vertices that underlies this isomorphism of simplicial sets describes the usual 1-categorical universal property. To say that the limit is conical and not merely 1-categorical is to assert that this universal property extends to all positive dimensions.

Inspecting Definition A.5.2, we see immediately that:

A.5.4. Proposition. A 1-categorical limit cone is conical just when it is preserved by all \( \mathcal{V} \)-valued representable functors \( \mathcal{C}(x, -) : \mathcal{C} \to \mathcal{V} \), while a 1-categorical colimit cone is conical just when it is preserved by all \( \mathcal{V} \)-valued representable functors \( \mathcal{C}(-, x) : \mathcal{C}^{\text{op}} \to \mathcal{V} \).

The proof of Lemma A.5.1 generalizes to show:

A.5.5. Proposition. In an enriched category with tensors all 1-categorical limits in \( \mathcal{C} \) are conical, while in an enriched category with cotensors all 1-categorical colimits are conical.

Proof. By Proposition A.5.4, to show that a 1-categorical limit in a \( \mathcal{V} \)-category \( \mathcal{C} \) is conical, it suffices to show that it is preserved by the \( \mathcal{V} \)-valued representable functors \( \mathcal{C}(x, -) : \mathcal{C} \to \mathcal{V} \) for all \( x \in \mathcal{C} \). If \( \mathcal{C} \) admits tensors, then each of these functors admits a left adjoint; as right adjoints, they necessarily preserve the 1-categorical limits of the statement.

In analogy with Proposition A.5.4, we have:

A.5.6. Proposition. Let \( \mathcal{C} \) be enriched and cotensored over \( \mathcal{V} \). A limit of an unenriched diagram \( F : \mathcal{J} \to \mathcal{C} \) is a conical limit if and only if it is preserved by cotensors with all objects \( v \in \mathcal{V} \).

Proof. Cotensors are \( \mathcal{V} \)-enriched right adjoints, which preserve conical limits. The content is that preservation by cotensors suffices to enriched a 1-categorical limit to a \( \mathcal{V} \)-categorical one.

By Proposition A.5.4, a 1-categorical limit cone \((\lambda_j : \ell \to F_j)_{j \in \mathcal{J}}\) is conical just when it is preserved by all \( \mathcal{V} \)-valued representable functors \( \mathcal{C}(x, -) : \mathcal{C} \to \mathcal{V} \). To see that the natural map

\[
\lambda_* : \mathcal{C}(x, \ell) \to \lim_{j \in \mathcal{J}} \mathcal{C} (x, F_j)
\]

is invertible, not necessarily a limit cone, composition with \( \lambda \) induces a \( \mathcal{V} \)-natural map \( \lambda_* : \mathcal{C}(x, \ell) \to \lim_{j \in \mathcal{J}} \mathcal{C} (x, F_j) \); see Exercise A.5.i. This is by essentially the same argument used in Example A.3.4 to demonstrate that arrows in the underlying category of an enriched category induce enriched natural transformations between representable functors. So the content of the universal property that characterizes conical limits is that this \( \mathcal{V} \)-natural map is invertible.
is an isomorphism in $\mathcal{V}$ we appeal to the unenriched Yoneda lemma and argue that this map induces an isomorphism upon applying an unenriched representable functor $\mathcal{V}(v, -)_0 : \mathcal{V} \to \mathsf{Set}$ for any $v \in \mathcal{V}$. To see this invertibility, note that the induced map of hom-sets fits into a commutative diagram

$$
\begin{array}{ccc}
\mathcal{V}(v, C(x, \ell))_0 & \xrightarrow{\lambda_*} & \mathcal{V}(v, \lim_{j \in \mathcal{J}} C(x, F_j))_0 \\
\cong & & \cong \\
\lim_{j \in \mathcal{J}} \mathcal{V}(v, C(x, F_j))_0 & \cong & \lim_{j \in \mathcal{J}} C(x, F_j)_0 \\
C(x, \ell^v)_0 & \xrightarrow{\lambda^v} & C(x, \lim_{j \in \mathcal{J}} (F_j)_0)
\end{array}
$$

where the vertical isomorphisms express the unenriched universal property of cotensors and the fact that unenriched representable functors preserve limits. To say that cotensors preserve the limit $\ell \cong \lim_{j \in \mathcal{J}} F_j$ means that $\ell^v \cong (\lim_{j \in \mathcal{J}} F_j)^v \cong \lim_{j \in \mathcal{J}} (F_j)_0^v$, so by the Yoneda lemma, the lower-horizontal map is an isomorphism, and thus the top-horizontal map is as well. \hfill \Box

**Exercises.**

A.5.i. **Exercise.** Consider a diagram $F : \mathcal{I} \to \mathcal{C}$ indexed by a 1-category and valued in a $\mathcal{V}$-category and a cone $\lambda : \Delta \ell \Rightarrow F$. Assuming $\mathcal{V}$ has $\mathcal{I}$-shaped limits, define a canonical map $\lambda_* : C(x, \ell) \to \lim_{j \in \mathcal{I}} C(x, F_j)$ and show, by arguing along the lines of Example A.3.4, that it is $\mathcal{V}$-natural.

A.5.ii. **Exercise.** Specialize the result of Proposition A.5.5 to prove the following: in any 2-category $\mathcal{C}$ that admits tensors with the walking-arrow category $\mathbb{Z}$, any 1-categorical limits that $\mathcal{C}$ admits are automatically conical.\textsuperscript{10}

A.6. **Weighted Limits and Colimits**

The cotensors of §A.4 and conical limits of §A.5 are both instances of a more general notion of weighted limit that we now introduce. We continue in the context of a complete and cocomplete cartesian closed symmetric monoidal category $(\mathcal{V}, \times, 1)$. The examples we have in mind are $(\mathsf{sSet}, \times, 1)$, its cartesian closed subcategory $(\mathsf{Cat}, \times, 1)$, or its further cartesian closed subcategory $(\mathsf{Set}, \times, 1)$.

Ordinary limits and colimits are objects representing the functor of cones with a given apex over or under a fixed diagram. **Weighted** limits and colimits are defined analogously, except that the cones over or under a diagram might have exotic “shapes,” which are allowed to vary with the objects indexing the diagram. More formally, in the $\mathcal{V}$-enriched context, the *weight*, defining the “shape” of a cone over a diagram indexed by $\mathcal{A}$ or under a diagram indexed by $\mathcal{A}^{op}$, takes the form of a functor in $\mathcal{V}^{\mathcal{A}}$.

We develop the general notions of weighted limit and weighted colimit from three different viewpoints that we introduce in the reverse of the logical order, because we find this route to be the most intuitive. We first describe the axioms that characterize the weighted limit and colimit bifunctors, whenever they exist. We then explain how weighted limits and colimits can be constructed, again assuming these exist. We then finally introduce the general universal property that defines a particular weighted limit or colimit, which stipulates exactly what is required for the notions just introduced to in fact exist.

\textsuperscript{10}The statement asserts that the presence of tensors with $\mathbb{Z}$ implies that the universal property of 1-dimensional limits automatically has an additional 2-dimensional aspect. See the discussion around Proposition 1.4.5 for an illustration of this and see [66, p. 306] for a proof.
A.6.1. Definition (weighted limits and colimits, axiomatically). For a small \( \mathcal{V} \)-enriched category \( \mathcal{A} \) and a large \( \mathcal{V} \)-enriched category \( \mathcal{C} \), the weighted limit and weighted colimit bifunctors

\[
\text{lim}^\mathcal{A} - : (\mathcal{V} \mathcal{A}^{\text{op}} \times \mathcal{C}\mathcal{A}) \to \mathcal{C} \quad \text{and} \quad \text{colim}^\mathcal{A} - : \mathcal{V} \mathcal{A} \times \mathcal{C}\mathcal{A}^{\text{op}} \to \mathcal{C}
\]

are characterized by the following pair of axioms whenever they exist:

(i) Weighted (co)limits with representable weights evaluate at the representing object:

\[
\text{lim}^\mathcal{A} \mathcal{A}(a,-) F \cong F_a \quad \text{and} \quad \text{colim}^\mathcal{A} \mathcal{A}(-,a) G \cong G_a.
\]

(ii) The weighted (co)limit bifunctors are cocontinuous in the weight: for any diagrams \( F \in \mathcal{C}\mathcal{A} \) and \( G \in \mathcal{C}\mathcal{A}^{\text{op}} \), the functor \( \text{colim}^\mathcal{A} - G \) preserves colimits, while the functor \( \text{lim}^\mathcal{A} - F \) carries colimits to limits.¹¹

We interpret axiom (ii) to mean that weights can be “made-to-order”: a weight constructed as a colimit of representables — as all \( \mathcal{V} \)-valued functors are — will stipulate the expected universal property.

A.6.2. Definition (weighted limits and colimits, constructively). The limit of \( F \in \mathcal{C}\mathcal{A} \) weighted by \( W \in \mathcal{V}\mathcal{A} \) is computed by the functor cotensor product:

\[
\text{lim}^\mathcal{A} W F \coloneqq \int_{a \in \mathcal{A}} Fa^W_a \coloneqq \text{eq} \left( \prod_{a \in \mathcal{A}} Fa^W_a \xrightarrow{\cong} \prod_{a,b \in \mathcal{A}} F^A(a,b) \times W_a \right),
\]

where the product and equalizer should be interpreted as conical limits in the sense of Definition A.5.2. The maps in the equalizer diagram are induced by the actions \( \mathcal{A}(a,b) \times Wa \to Wb \) and \( Fa \to Fb^A(a,b) \) of the hom-object \( \mathcal{A}(a,b) \) on the \( \mathcal{V} \)-functors \( W \) and \( F \); the latter case makes use of the natural isomorphism \( Fb^A(a,b) \times Wa \cong (Fb^A(a,b))^W_a \) of Lemma A.4.4.

Dually, the colimit of \( G \in \mathcal{C}\mathcal{A}^{\text{op}} \) weighted by \( W \in \mathcal{V}\mathcal{A} \) is computed by the functor tensor product:

\[
\text{colim}^\mathcal{A} W G \coloneqq \int^{a \in \mathcal{A}} Wa \otimes Ga \coloneqq \text{coeq} \left( \prod_{a \in \mathcal{A}} (Wa \times \mathcal{A}(a,b)) \otimes Gb \xrightarrow{\cong} \prod_{a \in \mathcal{A}} Wa \otimes Ga \right),
\]

where the coproduct and coequalizer should be interpreted as conical colimits. One of the maps in the coequalizer diagram is induced by the action \( \mathcal{A}(a,b) \otimes Gb \to Ga \) of \( \mathcal{A}(a,b) \) on the contravariant \( \mathcal{V} \)-functor \( G \) and the natural isomorphism \( (Wa \times \mathcal{A}(a,b)) \otimes Gb \cong Wa \otimes (\mathcal{A}(a,b) \otimes Gb) \) of Lemma A.4.4; the other uses the covariant action of \( \mathcal{A}(a,b) \) on \( W \) as before.

A.6.5. Definition (weighted limits and colimits, the universal property). The limit \( \text{lim}^\mathcal{A} W F \) of the diagram \( F \in \mathcal{C}\mathcal{A} \) weighted by \( W \in \mathcal{V}\mathcal{A} \) and the colimit \( \text{colim}^\mathcal{A} W G \) of \( G \in \mathcal{C}\mathcal{A}^{\text{op}} \) weighted by \( W \in \mathcal{V}\mathcal{A} \) are characterized by the universal properties:

\[
C(x, \text{lim}^\mathcal{A} W F) \cong \mathcal{V}\mathcal{A}(W, C(x,F)) \quad \text{and} \quad C(\text{colim}^\mathcal{A} W G, x) \cong \mathcal{V}\mathcal{A}(W, C(G,x)),
\]

each of these defining an isomorphism between objects of \( \mathcal{V} \).

¹¹More precisely, as will be proven in Proposition A.6.10, the weighted colimit functor \( \text{colim}^\mathcal{A} G \) preserves weighted colimits, while the weighted limit functor \( \text{lim}^\mathcal{A} F \) carries weighted colimits to weighted limits.
When the indexing category $\mathcal{A}$ is clear from context, as is typically the case, we frequently drop it from the notation for the weighted limit and weighted colimit. We now argue that these three definitions characterize the same objects. Along the way, we obtain results of interest in their own right, that we record separately.

A.6.7. Lemma. The category $\mathcal{V}$ admits all weighted limits, as defined by the formula of (A.6.3) satisfying the natural isomorphism of (A.6.6). Explicitly, for a weight $W: \mathcal{A} \to \mathcal{V}$ and a diagram $F: \mathcal{A} \to \mathcal{V}$, the weighted limit

$$\lim_{\mathcal{A}}^W F := \mathcal{V}^\mathcal{A}(W, F),$$

is the $\mathcal{V}$-object of $\mathcal{V}$-natural transformations from $W$ to $V$.

Proof. The $\mathcal{V}$-functor $\mathcal{V}(1, -): \mathcal{V} \to \mathcal{V}$ represented by the monoidal unit is naturally isomorphic to the identity functor. So taking $x = 1$ in the universal property of (A.6.6) in the case where the diagram $F \in \mathcal{V}^\mathcal{A}$ is valued in the $\mathcal{V}$-category $\mathcal{V}$, we have

$$\lim_{\mathcal{A}}^W F \cong \mathcal{V}^\mathcal{A}(W, F).$$

Simultaneously, the formula (A.6.3) computes the $\mathcal{V}$-object $\mathcal{V}^\mathcal{A}(W, F)$ of $\mathcal{V}$-natural transformations from $W$ to $F$ introduced in Definition A.3.8. □

The $\mathcal{V}$-object of $\mathcal{V}$-natural transformations satisfies the natural isomorphism

$$\mathcal{V}(v, \mathcal{V}^\mathcal{A}(W, F)) \cong \mathcal{V}^\mathcal{A}(W, \mathcal{V}(v, F))$$

for any $v \in \mathcal{V}$. Applying the observation that $W$-weighted limits of $\mathcal{V}$-valued functors are $\mathcal{V}$-objects of natural transformations to the functor $C(x, F -)$ and $C(G - , x)$ in the case of $F \in C^\mathcal{A}$ and $G \in C^{\mathcal{A}^{op}}$, we may re-express the natural isomorphism (A.6.6) as:

A.6.8. Corollary. The weighted limits and weighted colimits of (A.6.6) are representably defined as weighted limits in $\mathcal{V}$: for $W \in \mathcal{V}^\mathcal{A}$ and $F \in C^\mathcal{A}$ and $G \in C^{\mathcal{A}^{op}}$ the weighted limit and colimit are characterized by isomorphisms

$$C(x, \lim_W F) \cong \lim_W C(x, F) \quad \text{and} \quad C(\colim_W G, x) \cong \lim_W C(G, x)$$

(A.6.9)

natural in $x$ in $\mathcal{V}$. □

We now unify the Definitions A.6.1, A.6.2, and A.6.5.

A.6.10. Proposition. When the limits and colimits of (A.6.3) and (A.6.4) exist they define objects satisfying the universal properties (A.6.6) or equivalently (A.6.9) and bifunctors satisfying the axioms of Definition A.6.1.

Proof. The proofs are dual, so we confine our attention to the limit case. The general case of the implication Definition A.6.2 ⇒ A.6.5 — for either weighted limits or weighted colimits — is a direct consequence of the special case of this implication for weighted limits valued in $C = \mathcal{V}$ proven as Lemma A.6.7 and Corollary A.6.8. The limits of (A.6.3) in $C$ are also defined representably in terms of the analogous limits in $\mathcal{V}$. So the object defined by (A.6.3) represents the $\mathcal{V}$-functor $\lim_W C(-, F)$ that defines the weighted limit $\lim_W F$.

It remains to prove that the weighted limits of Definitions A.6.2 and A.6.5 satisfy the axioms of Definition A.6.1. In the case of a $\mathcal{V}$-valued diagram $F \in \mathcal{V}^\mathcal{A}$, axiom (i) is the $\mathcal{V}$-Yoneda lemma:

$$\mathcal{V}^\mathcal{A}(\mathcal{A}(a, -), F) \cong Fa$$
proven in Theorem A.3.11. Once again, the general case for \( F \in \mathcal{C}^\mathcal{A} \) follows from the special case for \( \mathcal{V} \)-valued diagrams, for to demonstrate an isomorphism \( \lim_{\mathcal{A}(a,-)} F \cong Fa \) in \( \mathcal{V} \) it suffices to demonstrate an isomorphism \( C(x, \lim_{\mathcal{A}(a,-)} F) \cong C(x, Fa) \) in \( \mathcal{V} \) for all \( x \in \mathcal{C} \) and have such a natural isomorphism by applying (A.6.9) and the observation just made to the functor \( C(x,-) \in \mathcal{V}^\mathcal{A} \).

For the axiom (ii), consider a diagram \( W : \mathcal{J}^{\text{op}} \to \mathcal{V}^\mathcal{A} \) of weights and a weight \( V \in \mathcal{V}^\mathcal{J} \) so that \( \text{colim}_V W \) is an object in \( \mathcal{V}^\mathcal{A} \). For any \( F \in \mathcal{C}^\mathcal{A} \), we will show that the \( \mathcal{V} \)-functor \( \lim_{\mathcal{A}} F : (\mathcal{V}^\mathcal{A})^{\text{op}} \to \mathcal{C} \) carries the \( V \)-weighted colimit of the diagram of weights \( W \) to the \( V \)-weighted limit of the composite diagram \( \lim_{\mathcal{A}} W F : \mathcal{J} \to \mathcal{C} \).

The universal property (A.6.6), applied first to the \( \text{colim}_V W \)-weighted limit of the diagram \( F \) and the object \( x \), and then to the \( V \)-weighted colimit of the diagram \( W \) and the object \( \mathcal{C}(x,F) \), supplies isomorphisms:

\[
C(x, \lim_{\mathcal{A}} \text{colim}_V W F) \cong \mathcal{V}^\mathcal{A}(\text{colim}_V W, \mathcal{C}(x,F)) \cong \mathcal{V}^\mathcal{J}(V, \mathcal{V}^\mathcal{A}(W, \mathcal{C}(x,F))).
\]

Applying (A.6.6) twice more, first for the weights \( W_j \) for each \( j \in \mathcal{J} \) and then for the weight \( V \) and the diagram \( \lim_{\mathcal{A}} F : \mathcal{J} \to \mathcal{C} \), we have

\[
\cong \mathcal{V}^\mathcal{J}(V, \mathcal{C}(x, \lim_{\mathcal{A}} W F)) \cong C(x, \text{colim}_V \lim_{\mathcal{A}} W F).
\]

By the Yoneda lemma, this proves that

\[
\lim_{\mathcal{A}} \text{colim}_V W F \cong \lim_{\mathcal{A}} \lim_{\mathcal{A}} W F,
\]

i.e., that the weighted limit functor \( \lim_{\mathcal{A}} F \) is carries a weighted colimit of weights to the analogous weighted limit of weights. □

A.6.11. REMARK (for unenriched indexing categories). When the indexing category is unenriched, the limit and colimit formulas from Definition A.6.2 simplify as follows

\[
\lim_{\mathcal{A}} F \cong \text{eq} \left( \prod_{a \in \mathcal{A}} F_a \overleftarrow{W_a} \right)
\]

\[
\text{colim}_{\mathcal{V}} G \cong \text{coeq} \left( \prod_{a \in \mathcal{A}} W_a \otimes G_a \overrightarrow{W_a} \right)
\]

and in fact, it suffices to consider only non-identity arrows or even just atomic arrows.

A.6.12. EXAMPLE (conical limits and colimits). For any small \( \mathcal{V} \)-category \( \mathcal{A} \), the constant diagram at the terminal object of \( \mathcal{V} \) defines the terminal weight \( 1 \in \mathcal{V}^{\mathcal{A}} \). For diagrams \( F \in \mathcal{C}^\mathcal{A} \) and \( G \in \mathcal{C}^{\mathcal{A}^{\text{op}}} \) respectively, limits and colimits weighted by this weight satisfy the defining universal properties

\[
C(x, \lim_1 F) \cong \mathcal{V}^{\mathcal{A}}(1, C(x,F)) \cong \lim_1 C(x,F)
\]

and

\[
C(\text{colim}_1 G, x) \cong \mathcal{V}^{\mathcal{A}}(1, C(G,x)) \cong \lim_1 C(G,x),
\]

which say that \( \lim F \) and \( \text{colim} G \) represent the functors of \( \mathcal{V} \)-enriched conical cones over \( F \) or under \( G \), respectively.

When \( \mathcal{A} \) is an unenriched category, this recovers the universal property that characterized the conical limits and conical colimits of Definition A.5.2, so we extend those terms to refer to general limits and colimits weighted by the terminal weight; it is common to use the simplified notation.
lim F := lim_1^A F and colim G := colim_1^A G for conical limits and colimits. This explains the name “conical”: among the weighted limits, the conical limits are the ones with ordinary cone shapes, involving a single arrow in the underlying category pointing from the summit to each object in the diagram. Thus, conical limits and colimits arise as special cases of weighted limits and colimits whose weights are terminal.

A.6.13. Example (tensors and cotensors). A diagram indexed by the terminal category 1 and valued in a V-enriched category C is just an object c ∈ C. A weight for such diagrams is just given by another object v ∈ V. The v-weighted limit of the diagram c is defined by the universal property

\[ C(x, \lim_v c) \cong C(x, c)^v \]

that characterizes the cotensor c^v, while the v-weighted colimit of the diagram c is defined by the universal property

\[ C(\operatorname{colim}_v c, x) \cong C(c, x)^v \]

that characterizes the tensor v⊗c. Thus, cotensors and tensors arise as special cases of weighted limits and colimits whose indexing categories are terminal.

A.6.14. Example (comas). An ∞-cosmos K is, in particular, a category enriched over simplicial sets. The comma ∞-category is the limit in the ∞-cosmos K of the diagram ↓→ K given by the cospan

\[ C \xrightarrow{g} A \leftarrow B \]

weighted by the diagram ↓→ sSet given by the cospan

\[ 1 \xrightarrow{1} 2 \leftarrow 0 \rightarrow 1 \]

Under the simplification of Remark A.6.11, the formula for the weighted limit reduces to the equalizer of the pair of maps

\[ C \times A^2 \times B \xrightarrow{\pi} A^2 \xrightarrow{\psi, p_0} A \times A \]

which computes the pullback of (3.4.2). The universal property (A.6.6) provides a correspondence between functors X → Hom_A(f, g) in K and simplicial natural transformations, the data of which is given by the three dashed vertical maps that fit into two commutative squares:

\[ \begin{array}{ccc}
1 & \xrightarrow{1} & 2 \leftarrow 0 & \rightarrow 1 \\
\downarrow & & \downarrow & & \downarrow \\
\text{Fun}(X, C) & \xrightarrow{g_*} & \text{Fun}(X, A) & \leftarrow & \text{Fun}(X, B)
\end{array} \]

A.6.15. Example (Bousfield-Kan homotopy limits). In their classic book on homotopy limits and colimits [22], Bousfield and Kan define the homotopy limit of a diagram indexed by a 1-category A and valued in a Kan-complex enriched category C to be the limit weighted by the functor

\[ A \xrightarrow{\rightarrow} sSet \]

\[ a \xrightarrow{\rightarrow} A_{/a} \]

which carries each object a ∈ A the nerve of the slice category over a.
A.6.16. Example (Kan extensions as weighted co/limits). The usual colimit or limit formula that computes the value of a pointwise left or right Kan extension of an unenriched functor $F: C \to E$ along $K: C \to D$ at an object $d \in D$ can be succinctly expressed by the weighted colimit or weighted limit

$$\text{lan}_K F(d) := \underset{D(\cdot, d)}{\text{colim}} F \quad \text{and} \quad \text{ran}_K F(d) := \underset{D(d, \cdot)}{\text{lim}} F.$$

The formulae of Definition A.6.2 give criteria under which weighted limits or colimits are guaranteed to exist.

A.6.17. Corollary. If $C$ is a $\mathcal{V}$-enriched category that admits cotensors and conical limits of all small unenriched diagram shapes, then $C$ admits all small weighted limits. Dually, if $C$ admits tensors and conical colimits of all small unenriched diagram shapes, then $C$ admits all small weighted colimits. □

A.6.18. Definition. A $\mathcal{V}$-category $C$ is complete if it admits all small $\mathcal{V}$-weighted limits, or equivalently, by Corollary A.6.17, if it admits cotensors and all small conical limits. Dually, a $\mathcal{V}$-category $C$ is cocomplete if it admits all small $\mathcal{V}$-weighted colimits, or equivalently, by Corollary A.6.17, if it admits tensors and all small conical colimits.

A.6.19. Remark (on proving enriched completeness). In practice one often shows that a $\mathcal{V}$-category $C$ is complete by exhibiting that its underlying category is complete and that $C$ has both cotensors and tensors, the latter being an instance of a weighted colimit. Then Proposition A.5.5 applies to establish that the unenriched limits are in fact conical limits.

We conclude with a few results from the general theory of weighted limits and colimits. Immediately from their defining universal properties, it can be verified that:

A.6.20. Lemma (weighted limits of restricted diagrams). Suppose given a $\mathcal{V}$-functor $K: \mathcal{A} \to \mathcal{B}$, a weight $W: \mathcal{A} \to \mathcal{V}$, and diagrams $F: \mathcal{B} \to \mathcal{C}$ and $G: \mathcal{B}^{\text{op}} \to \mathcal{C}$. Then the $W$-weighted limit or colimit of the restricted diagram is isomorphic to the $\text{lan}_K W$-weighted limit or colimit of the original diagram:

$$\text{lim}^{\mathcal{A}}_W (F \circ K) \cong \text{lim}^{\mathcal{B}}_{\text{lan}_K W} F \quad \text{and} \quad \text{colim}^{\mathcal{A}}_W (G \circ K) \cong \text{colim}^{\mathcal{B}}_{\text{lan}_K W} G.$$

Recall from Definition A.3.16 that an enriched adjunction is comprised of a pair of $\mathcal{V}$-functors $F: \mathcal{B} \to \mathcal{A}$ and $U: \mathcal{A} \to \mathcal{B}$ together with a family of isomorphisms $\mathcal{A}(Fb, a) \cong \mathcal{B}(b, Ua)$ that are $\mathcal{V}$-natural in both variables. The usual Yoneda-style argument enriches to show:

A.6.21. Proposition (weighted RAPL/LAPC). A $\mathcal{V}$-enriched right adjoint functor $U: \mathcal{A} \to \mathcal{B}$ preserves all weighted limits that exist in $\mathcal{A}$, while its $\mathcal{V}$-enriched left adjoint $F: \mathcal{B} \to \mathcal{A}$ preserves all weighted colimits that exist in $\mathcal{B}$.

Proof. Exercise A.6.iii. □

Exercises.

A.6.i. Exercise. Taking the base for enrichment $\mathcal{V}$ to be $\text{Set}$, compute the following weighted limits of a simplicial set $X$, regarded as a diagram in $\text{Set}^{\Delta^{\text{op}}}$, weighted by:

(i) the standard $n$-simplex $\Delta[n] \in \text{Set}^{\Delta^{\text{op}}}$,

(ii) the spine of the $n$-simplex, the simplicial subset $\Gamma[n] \hookrightarrow \Delta[n]$ obtained by gluing together the $n$ edges from $i$ to $i+1$ into a composable path,
(iii) the \( n \)-simplex boundary \( \partial \Delta[n] \in \text{Set}^{\Delta^\op} \).\(^{12}\)

(i) Extend the definitions of weighted limit and colimit to allow the weight \( W \) to be an enriched profunctor—i.e., a \( \mathcal{V} \)-functor \( W: \mathcal{B}^\op \times \mathcal{A} \to \mathcal{V} \) for small \( \mathcal{V} \)-categories \( \mathcal{A} \) and \( \mathcal{B} \)—in such a way that the weighted limit and colimit functors have the form

\[
\begin{align*}
(\mathcal{V}^{\mathcal{B}^\op \times \mathcal{A}})^{\mathcal{A}} \times \mathcal{A} \xrightarrow{\lim} \mathcal{C}^{\mathcal{B}} \quad \text{and} \quad \mathcal{V}^{\mathcal{B}^\op \times \mathcal{A}} \times \mathcal{B} \xrightarrow{\text{colim}} \mathcal{C}^{\mathcal{A}}
\end{align*}
\]

(ii) Show that the weighted limit and weighted colimit bifunctors from (i) form two thirds of a two-variable adjunction, with a \( \mathcal{V} \)-natural isomorphism

\[\mathcal{C}^{\mathcal{A}}(\text{colim}_W G, F) \cong \mathcal{C}^{\mathcal{B}}(G, \lim_W F)\]

for \( W \in \mathcal{V}^{\mathcal{B}^\op \times \mathcal{A}}, F \in \mathcal{C}^{\mathcal{A}}, \) and \( G \in \mathcal{C}^{\mathcal{B}} \).

(iii) What is the third bifunctor of the two-variable adjunction of (ii)?

A.7. Change of Base

“Change of base,” first considered by Eilenberg and Kelly in [40], refers to a systematic procedure by which enrichment over one category \( \mathcal{V} \) is converted into enrichment over another category \( \mathcal{W} \). We’ve seen that for a cartesian closed category \( \mathcal{V} \), there is a 2-category \( \mathcal{V}\text{-Cat} \) of \( \mathcal{V} \)-categories, \( \mathcal{V} \)-functors, and \( \mathcal{V} \)-natural transformations. The first main result, appearing as Proposition A.7.3 below, gives conditions under which a functor \( T: \mathcal{V} \to \mathcal{W} \) between cartesian closed categories induces a change-of-base 2-functor \( T_*: \mathcal{V}\text{-Cat} \to \mathcal{W}\text{-Cat} \).

As the context we are working in here is less general than the one considered by Eilenberg and Kelly—we base categories are cartesian closed while theirs are closed symmetric monoidal—we take a shortcut that leads us towards a special case of their result which covers our examples and is easier to explain. In general, all that is needed to produce a change of base 2-functor is a lax monoidal functor between symmetric monoidal categories, but the lax monoidal functors we encounter between cartesian closed categories are in fact finite-product-preserving, so we content ourselves with explicating the results in that case instead.

Recall that a functor \( T: \mathcal{V} \to \mathcal{W} \) between cartesian closed categories preserves finite products just when the natural maps defined for any \( u, v \in \mathcal{V} \)

\[T(u \times v) \cong T(u) \times T(v) \quad \text{and} \quad T(1) \cong 1\]

are isomorphisms. For example:

A.7.1. Example. Since representable functors preserve products, for any cartesian closed category \( \mathcal{V} \), the underlying set functor \((-)_0: \mathcal{V} \to \text{Set} \) is product-preserving.

A.7.2. Example. In a cartesian closed category \( \mathcal{V} \), finite products distribute over arbitrary coproducts. In particular, for any sets \( X \) and \( Y \) there is an isomorphism

\[\bigsqcup_{X \times Y} 1 \cong (\bigsqcup_X 1) \times (\bigsqcup_Y 1)\]

\(^{12}\)The limit of a simplicial object weighted by \( \partial \Delta[n] \) is called the \( n \)-th matching object; see Appendix C.
between coproducts of the terminal object 1, which proves that the functor 
\[ \text{Set} \xrightarrow{T} \mathcal{V} \]

is finite-product-preserving.

A product-preserving functor may be used to change the base as follows

A.7.3. Proposition. A product-preserving functor \( T: \mathcal{V} \to \mathcal{W} \) between cartesian closed categories induces a change-of-base 2-functor 
\[ T_*: \mathcal{V}\text{-Cat} \to \mathcal{W}\text{-Cat}. \]

An early observation along these lines was first stated as [40, II.6.3], with the proof left to the reader. We adopt the same tactic and leave the diagram chases to the reader or to [31, 4.2.4] and instead just give the construction of the change-of-base 2-functor, which is the important thing.

Proof. Let \( \mathcal{C} \) be a \( \mathcal{V} \)-category and define a \( \mathcal{W} \)-category \( T_!\mathcal{C} \) to have the same objects and to have mapping objects 
\[ T_!\mathcal{C}(x,y) := T\mathcal{C}(x,y). \]

The composition and identity maps are given by the composites 
\[ T\mathcal{C}(y,z) \times T\mathcal{C}(x,y) \xrightarrow{=} T(\mathcal{C}(y,z) \times \mathcal{C}(x,y)) \xrightarrow{T} T\mathcal{C}(x,z) \quad 1 \xrightarrow{=} T1 \xrightarrow{T\text{id}} T\mathcal{C}(x,x) \]

which make use of the inverses of the natural maps that arise when a product-preserving functor is applied to a product. A straightforward diagram chase verifies that \( T_!\mathcal{C} \) is a \( \mathcal{W} \)-category.

If \( F: \mathcal{C} \to \mathcal{D} \) is a \( \mathcal{V} \)-functor, then we define a \( \mathcal{W} \)-functor \( T_*F: T_!\mathcal{C} \to T_!\mathcal{D} \) to act on objects by 
\[ c \in \mathcal{C} \mapsto Fc \in \mathcal{D} \]

and with internal action on arrows defined by 
\[ T\mathcal{C}(x,y) \xrightarrow{T_Fx,y} T\mathcal{D}(Fx,Fy) \]

Again, a straightforward diagram chase verifies that \( T_*F \) is \( \mathcal{V} \)-functorial. It is evident from this definition that \( T_*(GF) = T_!G \cdot T_*F \).

Finally, let \( \alpha: F \Rightarrow G \) be a \( \mathcal{V} \)-natural transformation between \( \mathcal{V} \)-functors \( F, G: \mathcal{C} \to \mathcal{D} \) and define a \( \mathcal{W} \)-natural transformation \( T_*\alpha: T_*F \Rightarrow T_*G \) to have components 
\[ 1 \xrightarrow{=} T1 \xrightarrow{T\alpha_c} T\mathcal{D}(Fc,Gc) \]

Another straightforward diagram chase verifies that \( T_*\alpha \) is \( \mathcal{W} \)-natural.

It remains to verify this assignment is functorial for both horizontal and vertical composition of enriched natural transformations. Consulting Lemma A.3.5, we see that the component of \( T_*(\beta \cdot \alpha) \) is defined by the top-horizontal composite while the component of the vertical composite of \( T_!\alpha \) with \( T_!\beta: T_*G \Rightarrow T_*H \) is defined by the bottom composite:
\[ 1 \xrightarrow{=} T1 \xrightarrow{T(\beta_c \times \alpha_c)} T(D(Gc,Hc) \times D(Fc,Gc)) \xrightarrow{T} T\mathcal{D}(Fc,Hc) \]

The square commutates by the naturality of the isomorphism \( T(u \times v) \cong Tu \cong Tv \), while the triangle commutes because 1 is terminal, so the inverses of these isomorphisms form a commutative triangle. The argument for functoriality of horizontal composites is similar. \[ \square \]
As a special case, we deduce the unproven claims of Corollary A.3.6.

A.7.4. COROLLARY. For any cartesian closed category \( \mathcal{V} \) with coproducts, the underlying category construction and free category construction define 2-functors \( \mathcal{V}\text{-Cat} \to \text{Cat} \) and \( \text{Cat} \to \mathcal{V}\text{-Cat} \). □

A.7.5. REMARK. In fact, the “change of base” procedure \( \mathcal{V} \mapsto \mathcal{V}\text{-Cat} \) is itself a 2-functor from the 2-category of cartesian closed categories, finite-product-preserving functors, and natural transformations to the 2-category of 2-categories, 2-functors, and 2-natural transformations. See [31, §4.3] for a discussion and proof.

As an immediate consequence of the 2-functoriality of Remark A.7.5:

A.7.6. PROPOSITION. Any adjunction between cartesian closed categories whose left adjoint preserves finite products induces a change-of-base 2-adjunction

\[
\begin{array}{ccc}
\mathcal{V} & \xleftshort{F} & \xrightshort{U} & \xrightarrow{\sim} & \mathcal{V}\text{-Cat} & \xleftshort{F_*} & \xrightshort{U_*} & \xrightarrow{\sim} & \mathcal{W}\text{-Cat}
\end{array}
\]

PROOF. Of course right adjoints always preserve products, so the adjoint pair of functors \( F \rightarrow U \) defines an adjunction in the 2-category of cartesian closed categories and finite-product-preserving functors described in Remark A.7.5. The 2-functor \( \mathcal{V} \mapsto \mathcal{V}\text{-Cat} \) then carries the adjunction displayed on the left to the adjunction displayed on the right. □

In light of Proposition A.7.6 and results to follow, an adjunction between cartesian closed categories whose left adjoint preserves finite products provides a particularly convenient change-of-base adjunction. For example, the product-preserving functors of Examples A.7.1 and A.7.2 are adjoints, giving rise to the change-of-base 2-adjunction

\[
\begin{array}{ccc}
\text{Cat} & \xleftshort{\bot} & \xrightarrow{(-)_0} & \mathcal{V}\text{-Cat}
\end{array}
\]

promised in Proposition A.2.8.

While Proposition A.7.6 provides an opportunity to change enrichments along either adjoint of a finite-product-preserving adjunction, the next series of results will show that change of base along the right adjoint is somewhat better behaved.

A.7.7. PROPOSITION. Given a change-of-base adjunction between cartesian closed categories whose left adjoint preserves finite products

\[
\begin{array}{ccc}
\mathcal{V} & \xleftshort{F} & \xrightshort{U} & \xrightarrow{\sim} & \mathcal{W}
\end{array}
\]

then if \( C \) is tensored or cotensored as a \( \mathcal{W}\)-category, then \( \mathcal{U}_*C \) is tensored or cotensored as \( \mathcal{V}\)-category with the tensor or cotensor of \( c \in C \) by \( v \in \mathcal{V} \) defined by

\[
\forall \otimes c := Fv \otimes c \quad \text{and} \quad c^v := c^{Fv}.
\]

PROOF. The statements are dual. Suppose \( C \) admits cotensors as a \( \mathcal{W}\)-category. To verify that \( \mathcal{U}_*C \) admits cotensors as a \( \mathcal{V}\)-category we must supply an isomorphism

\[
\mathcal{U}(x, c^{Fv}) \cong (\mathcal{U}(x, c))^v
\]

450
in 
\( \mathcal{V} \) that is \( \mathcal{V} \)-natural in \( x \). By the enriched Yoneda lemma, we can extract this isomorphism from an isomorphism
\[
\mathcal{V}(u, \mathcal{U}C(x, c^{Fv})) \cong \mathcal{V}(u, (\mathcal{U}C(x, c))^v)
\]
that is \( \mathcal{V} \)-natural in \( u \in \mathcal{V} \). To that end, we have
\[
\mathcal{V}(u, \mathcal{U}C(x, c^{Fv})) \cong \mathcal{U}W(Fu, C(x, c^{Fv})) \cong \mathcal{U}W(Fu, C(x, c)) \cong \mathcal{V}(u \times v, \mathcal{U}C(x, c)) \cong \mathcal{V}(u, (\mathcal{U}C(x, c))^v),
\]
by composing the \( \mathcal{V} \)-natural isomorphisms of Lemma A.7.8 arising from the adjunction \( F \dashv \mathcal{U} \), the enriched natural isomorphisms arising from the cartesian closed structure on \( \mathcal{V} \) and on \( \mathcal{U}_*\mathcal{W} \), and the fact that \( F \) preserves binary products. □

A.7.8. LEMMA. Any adjunction comprised of finite-product-preserving functors between cartesian closed categories
\[
\begin{array}{ccc}
\mathcal{V} & \xleftarrow{F} & \mathcal{W} \\
\downarrow \mathcal{U} & & \downarrow \mathcal{U} \\
\mathcal{U}_*\mathcal{W} & \xrightarrow{\eta} & \mathcal{V}
\end{array}
\]
defines a \( \mathcal{V} \)-enriched adjunction between the \( \mathcal{V} \)-categories \( \mathcal{V} \) and \( \mathcal{U}_*\mathcal{W} \); i.e., there exists a \( \mathcal{V} \)-natural isomorphism
\[
\mathcal{U}W(Fv, w) \cong \mathcal{V}(v, \mathcal{U}w).
\]

PROOF. It’s easy to verify the \( \mathcal{V} \)-functoriality of \( \mathcal{U} : \mathcal{U}_*\mathcal{W} \rightarrow \mathcal{V} \), which implies that for all \( v \in \mathcal{V} \), the map
\[
\mathcal{U}W(Fv, w) \xrightarrow{\mathcal{U}Fv,w} \mathcal{V}(\mathcal{U}Fv, \mathcal{U}w) \xrightarrow{- \circ \eta_v} \mathcal{V}(v, \mathcal{U}w)
\]
is \( \mathcal{V} \)-natural in \( w \in \mathcal{U}_*\mathcal{W} \). By Remark A.3.17, to construct a compatible \( \mathcal{V} \)-enrichment of \( F \), we need only demonstrate that this map in an isomorphism in \( \mathcal{V} \).

We do this by constructing an explicit inverse, namely
\[
\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\eta} \mathcal{U}F\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\mathcal{U}(Fv, \mathcal{U}w)} \mathcal{U}W(Fv, \mathcal{U}w) \xrightarrow{\epsilon_w \circ -} \mathcal{U}W(Fv, w)
\]
where the middle map is defined by applying the unenriched functor \( \mathcal{U} \) to the canonical action map \( Fv, \mathcal{U}w : F\mathcal{V}(v, \mathcal{U}w) \rightarrow \mathcal{W}(Fv, \mathcal{U}w) \) from the \( \mathcal{W} \)-functor \( F : F, \mathcal{V} \rightarrow \mathcal{W} \).

The proof that this maps are inverses involves a pair of diagram chases, the first of which demonstrates that the top-right composite reduces to the left-bottom composite, which is the identity:
\[
\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\eta} \mathcal{U}F\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\mathcal{U}(Fv, \mathcal{U}w)} \mathcal{U}W(Fv, \mathcal{U}w) \xrightarrow{\epsilon_w \circ -} \mathcal{U}W(Fv, w)
\]
\[
\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\eta \circ \mathcal{U}w} \mathcal{V}(\mathcal{U}Fv, \mathcal{U}w) \xrightarrow{\mathcal{U}\epsilon_v \circ -} \mathcal{V}(\mathcal{U}Fv, \mathcal{U}w) \xrightarrow{\epsilon_w \circ -} \mathcal{V}(v, \mathcal{U}w)
\]
\[
\mathcal{V}(v, \mathcal{U}w) \xrightarrow{\eta \circ \mathcal{U}w} \mathcal{V}(\mathcal{U}Fv, \mathcal{U}w) \xrightarrow{\mathcal{U}\epsilon_v \circ -} \mathcal{V}(\mathcal{U}Fv, \mathcal{U}w) \xrightarrow{\epsilon_w \circ -} \mathcal{V}(v, \mathcal{U}w)
\]
The only subtle point is the commutativity of the trapezoidal region, which expresses the fact that \( \eta : \text{id}_\mathcal{V} \Rightarrow UF \) is a closed natural transformation between product-preserving functors between cartesian closed categories. This region commutes because the transposed diagram does:

\[
\begin{array}{c}
v \times \mathcal{V}(v, Uw) \\
\eta_v \times \eta \\
UFv \times UF\mathcal{V}(v, Uw) \\
\cong \\
UF(v \times \mathcal{V}(v, Uw)) \\
\eta_{Uw} \\
UFUw
\end{array}
\]

the right-hand square by naturality, and the left-hand square because any naturally transformation between product-preserving functors is automatically a monoidal natural transformation; see Exercise A.7.i. The other diagram chase is similar.

This theory of change of base is all well and good from the compound noun perspective on enriched categories, but an additional concern arises from the adjectival point of view. If the finite-product-preserving functor \( T : \mathcal{V} \to \mathcal{W} \) commutes with the underlying set functors for \( \mathcal{V} \) and \( \mathcal{W} \) up to natural isomorphism, then by the 2-functoriality of Remark A.7.5, the change-of-base 2-functor \( T^* : \mathcal{V}\text{-Cat} \to \mathcal{W}\text{-Cat} \) also preserves the underlying categories up to natural isomorphism. This happens in particular in the following setting.

A.7.9. Lemma. Consider a finite-product-preserving adjunction between cartesian closed categories:

\[
\begin{array}{c}
\mathcal{V} \\
U \\
\mathcal{W}
\end{array}
\]

Then change of base along the right adjoint respects the underlying categories:

\[
\begin{array}{c}
\mathcal{W}\text{-Cat} \\
(-)_0 \\
\mathcal{V}\text{-Cat} \\
(-)_0 \\
\text{Cat}
\end{array}
\]

Proof. Let \( C \) be a \( \mathcal{W} \) category. Then the hom-set in the underlying category of \( U, C \) from \( x \) to \( y \) is isomorphic to the corresponding hom-set

\[
U, C(x, y)_0 := \mathcal{W}(1, U\mathcal{C}(x, y)) \cong \mathcal{V}(F1, C(x, y)) \cong \mathcal{V}(1, C(x, y)) \cong C(x, y)_0
\]

in the category underlying \( C \) and moreover this isomorphism respects the composition and identities in the underlying categories. Thus \( C_0 \cong U C_0 \). A similar argument shows that change of base along \( U \) respects underlying functors and natural transformations.

We close this chapter by returning to an example previewed in Digression 1.4.2.

A.7.10. Example. Both adjoints of the adjunction

\[
\begin{array}{c}
s\text{Set} \\
(\cdot) \\
\text{Cat}
\end{array}
\]
of Proposition 1.1.11 preserve finite products. Hence, Proposition A.7.6 induces a change-of-base adjunction defined by the 2-functors

\[
\begin{align*}
\text{Set-} & \quad \text{Cat} \\
\text{h}_* & \\
\text{2-Cat} & \quad \text{h}^* \\
\end{align*}
\]

that act identically on objects and act by applying the homotopy category functor or nerve functor, respectively, on homs. By Lemma A.7.9, the right adjoint, which builds a simplicially enriched category from a 2-category, respects the underlying category: the underlying category of objects and 1-cells is identified with the underlying category of objects and 0-arrows. In this case, the functor \( h: \text{sSet} \to \text{Cat} \) commutes with the underlying set functors, so in fact both adjoints preserve underlying categories, as is evident from direct computation. In particular, the homotopy 2-category of an \( \infty \)-cosmos has the same underlying 1-category.

**Exercises.**

A.7.i. **Exercise.** Look up the definition of monoidal functor and monoidal transformation — sometimes referred to as a lax monoidal functor and a lax monoidal transformation — and show that

(i) any product-preserving functor between categories with finite products is monoidal, and

(ii) any natural transformation between such functors is a monoidal natural transformation.

A.7.ii. **Exercise.** Let \( \mathcal{V} \) be a cartesian closed category and suppose \( \mathcal{C} \) is a tensored and cotensored \( \mathcal{V} \)-category. By Proposition A.7.7, the underlying category \( \mathcal{C}_0 \) is tensored and cotensored as an unenriched category. Describe these tensors and cotensors.
APPENDIX B

An Introduction to 2-Category Theory

An important special case of enriched category theory arises when the base for enrichment is the cartesian closed category of categories themselves. 2-categories — categories enriched in $\mathbf{Cat}$ — and double categories — categories defined internally to $\mathbf{Cat}$ — were first introduced by Charles Ehresmann. A notable early expository account appeared in [68], while a comprehensive modern treatment is given by [57]. The basic definitions are given in §B.1, which pays particular attention to the composition of 2-cells in a 2-category by means of pasting.

In §B.2, we briefly answer the question: what do 2-categories form? We define three dimensions of morphisms between 2-categories — the 2-functors, 2-natural transformations, and modifications — and observe that these collectively assemble into a 3-category, this being a category enriched over the cartesian closed category of 2-categories.

There are many aspects of the theory of 2-categories that fall outside the purview of enriched category theory. We meet some of these in §B.3, where we develop the calculus of adjunctions and mates in any 2-category, complementing the results of §2.1, and in §B.4, where we study the special case of right adjoint right inverse adjunctions. §B.5 develops a lemma that produces absolute lifting diagrams that are preserved by any 2-functor. Finally, in §B.6 we consider the representability of various 2-categorical structures and comment briefly on the bicategorical Yoneda lemma.

B.1. 2-Categories and the Calculus of Pasting Diagrams

The category $\mathbf{Cat}$ of small categories is cartesian closed with the exponential $B^A$ defined to be the category of functors and natural transformations from $A$ to $B$ and a terminal object given by the terminal category $\mathbb{1}$. Exploiting the work in Appendix A, we can concisely define a 2-category to be a category enriched over this cartesian closed category. Lemma A.2.3 then provides our first example: since any cartesian closed category is enriched over itself, $\mathbf{Cat}$ defines an example of 2-category—the prototypical example.

Unpacking Definition A.2.1 when the base of enrichment is $\mathbf{Cat}$, we see that a 2-category contains a considerable amount of structure:

B.1.1. DEFINITION (2-category). A 2-category $\mathbf{C}$ is a category enriched in $\mathbf{Cat}$. Explicitly it has:

- a collection of objects $a, b$;
- a collection of arrows $f : a \rightarrow b$, frequently called 1-cells, these being the objects of the hom-categories $\mathbf{C}(a, b)$; and
• a collection of arrows between arrows \( a \xrightarrow{f} b \), called 2-cells,¹ these being the morphisms of the hom-categories \( \mathcal{C}(a, b) \) from \( f \) to \( g \) so that:

(i) For each fixed pair of objects \( a, b \in \mathcal{C} \), the 1-cells and 2-cells form a category. In particular:

• A pair of 2-cells as below-left admits a vertical composite as below-right:

\[
\begin{array}{c}
a \xrightarrow{g} b \\
\downarrow f \\
\downarrow h
\end{array}
\quad =:
\begin{array}{c}
a \xrightarrow{\beta \alpha} b \\
\downarrow h
\end{array}
\]

• Each 1-cell \( f : a \to b \) has an identity 2-cell \( a \xrightarrow{\text{id}_f} b \).

(ii) The objects and 1-cells define a category in the ordinary sense; in particular, each object has an identity arrow \( \text{id}_a : a \to a \).

(iii) The objects and 2-cells form a category. In particular:

• A pair of 2-cells as below-left admits a horizontal composite as below-right:

\[
\begin{array}{c}
a \xrightarrow{g} b \\
\downarrow f \\
\downarrow k
\end{array}
\quad =:
\begin{array}{c}
a \xrightarrow{j \alpha} c \\
\downarrow k
\end{array}
\]

• The identity 2-cells on identity 1-cells

\[
\begin{array}{c}
a \xrightarrow{\text{id}_a} a \\
\downarrow \text{id}_a
\end{array}
\]

define identities for horizontal composition.

(iv) Finally, the horizontal composition is functorial with respect to the vertical composition:

• The horizontal composite of the identity 2-cells is an identity 2-cell:

\[
\begin{array}{c}
a \xrightarrow{\text{id}_a} b \\
\downarrow \text{id}_k
\end{array}
\quad =
\begin{array}{c}
a \xrightarrow{\text{id}_b} c \\
\downarrow \text{id}_k
\end{array}
\]

• In the situation below, the horizontal composite of the vertical composites coincides with the vertical composite of the horizontal composites, a property referred to as middle-four

¹Implicit in this graphical representation is the requirement that a 2-cell \( \alpha \) has a domain 1-cell \( f \) and a codomain 1-cell \( g \), and these 1-cells have a common domain object \( a \) and codomain object \( b \). The objects \( a \) and \( b \) may be referred to as the 0-cell source and 0-cell target of \( \alpha \).
interchange:

\[
\begin{array}{ccc}
\varepsilon_f & \triangleright a & \beta_i \\
\delta & \triangleright b & \gamma \\
\delta & \triangleright c & \ell
\end{array}
\]

\[
(\delta \ast \beta) \cdot (\gamma \ast \alpha) = (\delta \cdot \gamma) \ast (\beta \cdot \alpha)
\]

A degenerate special case of horizontal composition, in which all but one of the 2-cells is an identity \(\text{id}_f\) on its boundary 1-cell \(f\), is called “whiskering.”

B.1.2. Definition (whiskering). The whiskered composite of a 2-cell \(a \xrightarrow{f} b\) with a pair of 1-cells \(k : x \to a\) and \(h : b \to y\) is defined by the horizontal composite:

\[
\begin{array}{ccc}
x & \xrightarrow{hfk} & y \\
\beta & \triangleright a & \gamma \\
\alpha & \triangleright b & \delta
\end{array}
\]

As the following lemma reveals, horizontal composition can be recovered from vertical composition and whiskering. Our primary interest in this result, however, has to with a rather prosaic consequence appearing as the final part of the statement, which is surprisingly frequently apposite

B.1.3. Lemma (naturality of whiskering). For any horizontally-composable pair of 2-cells in a 2-category there is a commutative square in the hom-category from the domain object to the codomain object formed by the whiskered cells whose diagonal defines the horizontal composite:

\[
\begin{array}{ccc}
C \ni & a & \xrightarrow{f} & b \\
\alpha & \triangleright & \beta \\
\gamma & \triangleright & \delta
\end{array}
\]

\[
\beta \cdot \alpha
\]

In particular, if any three of the four whiskered 2-cells \(h \alpha, k \alpha, \beta \cdot f, \beta \cdot g\) are invertible, so is the fourth.

Proof. By middle-four interchange:

\[
\beta \cdot g \cdot h \alpha = (\beta \cdot \text{id}_g) \cdot (\text{id}_h \cdot \alpha) = (\beta \cdot \text{id}_g) \cdot (\text{id}_h \cdot \alpha) = \beta \cdot \alpha = (\text{id}_k \cdot \beta) \cdot (\alpha \cdot \text{id}_f) = (\text{id}_k \cdot \alpha) \cdot (\beta \cdot \alpha) = k \alpha \cdot \beta f.
\]

The operations of horizontal and vertical composition are special cases of composition by pasting, an operation first introduced by Bénabou [7]. The main result, proven in the 2-categorical context by Power [88] is that a well-formed pasting diagram such as

\[
\begin{array}{ccc}
a & \xrightarrow{f} & b \\
\gamma & \triangleright & \alpha \\
\delta & \triangleright & \beta
\end{array}
\]

(B.1.4)
has a unique 2-cell composite.² We leave the formal statement and proof of this result to the literature and instead describe informally how such pasting composites should be interpreted.

B.1.5. Digression (how to read a pasting diagram). A pasting diagram in a 2-category \( \mathcal{C} \) represents a unique composite 2-cell, defining a morphism in one of the hom-categories between a pair of objects. To identify these objects, look at the underlying directed graph of objects and 1-cells in the pasting diagram. If the pasting diagram is well-formed, that graph will have a unique source object \( a \) and a unique target object \( z \). This indicates that the pasting diagram defines a 2-cell in the hom-category \( \mathcal{C}(a, z) \). The object \( a \) is its \textbf{source 0-cell} and the object \( z \) is its \textbf{target 0-cell}.

The next step is to identify the source 1-cell and the target 1-cell of the pasting diagram. These will both be objects of \( \mathcal{C}(a, z) \), i.e., 1-cells in the 2-category from \( a \) to \( z \). Again if the pasting diagram is well-formed, the \textbf{source 1-cell} will be the unique composable path of 1-cells none of which occur as part of the codomain of any 2-cell in the pasting diagram. In the diagram (B.1.4), these are the 1-cells whose labels appear above the arrow, and their composite is \( hgf \). Dually, the \textbf{target 1-cell} will be the unique composable path of 1-cells, none of which occur as part of the domain of any 2-cell in the pasting diagram. In (B.1.4), these are the 1-cells whose labels appear below the diagram, and their composite is \( trp \).

The final step is to represent the pasting diagram as a vertical composite of 2-cells, each of which is a map between a pair of composite 1-cells from \( a \) to \( z \) that trace a composable path through the directed graph underlying the pasting diagram. Each 2-cell in the pasting diagram will label precisely one of the 2-cells of this composite. The expressions of these vertical 2-cell composites are not necessarily unique and may not necessarily pass through every possible composable path of 1-cells (though there will be some vertical composite of 2-cells that does pass through each path of 1-cells).

To start, pick any 2-cell in the pasting diagram whose 1-cell source can be found as a subsequence of the source 1-cell; in the (B.1.4), either \( \alpha \) or \( \beta \) can be chosen first. Whisker it so that it defines a 2-cell from the source 1-cell \( hgf \) to another path of composable 1-cells from \( a \) to \( z \) through the pasting diagram. Then this whiskered composite forms the first step in the sequence of composable 2-cells. Remove this part of the pasting diagram and repeat until you arrive at the target 1-cell. In the example above, there are three possible ways to express the composite pasted cell (B.1.4) as vertical composites of whiskered 2-cell, represented by the three paths through the following commutative diagram in the category \( \mathcal{C}(a, z) \):

\[
\begin{array}{c}
hgf \\ \downarrow \beta gf
\end{array} \xrightarrow{haf} \begin{array}{c}hkjf \\ \downarrow \beta kjf
\end{array} \xrightarrow{hjy} \begin{array}{c}hkjn \\ \downarrow \beta kjn
\end{array} \in \mathcal{C}(a, z)
\]

\[
\begin{array}{c}
m\ell gf \\ \xrightarrow{m\ell ad}
\end{array} \xrightarrow{m\ell kjia} \begin{array}{c}m\ell kjn \\ \xrightarrow{m\ell kjy}
\end{array} \xrightarrow{m\ell kd} \begin{array}{c}m\ell kqp \\ \xrightarrow{m\ell kpq}
\end{array} \xrightarrow{mep} \begin{array}{c}msr \quad \xrightarrow{msr}
\end{array}
\]

\[\xrightarrow{\varphi} trp\]

A 2-category has four duals, including itself, each of which have the same objects, 1-cells, and 2-cells, but with some domains and codomains swapped.

B.1.6. Definition (op and co duals). Let \( \mathcal{C} \) be a 2-category.

- Its \textbf{op-dual} \( \mathcal{C}^{\text{op}} \) is the 2-category with \( \mathcal{C}^{\text{op}}(a, b) := \mathcal{C}(b, a) \). This reverses the direction of the 1-cells but not the 2-cells.

²This result was generalized to the bicategorical context by Verity [126], in which case the composite 2-cell is well-defined once its source and target 1-cells are specified. See also [56].
• Its co-dual $C^{\text{co}}$ is the 2-category with $C^{\text{co}}(a, b) := C(a, b)^{\text{op}}$. This reverses the direction of the 2-cells but not the 1-cells.

• Its coop-dual $C^{\text{coop}}$ is the 2-category with $C^{\text{coop}}(a, b) := C(b, a)^{\text{op}}$. This reverses the direction of both the 2-cells and the 1-cells.

Further details about the specification of $C^{\text{op}}$, $C^{\text{co}}$, and $C^{\text{coop}}$ as $\text{Cat}$-enriched categories are left to Exercise B.1.ii.

B.1.7. Digression (notions of sameness inside a 2-category). From the point of view of 2-category theory, the most natural notion of “sameness” for two objects of a 2-category is equivalence: $a$ and $b$ are to be regarded as the same, if there exist 1-cells $f: a \to b$ and $g: b \to a$ together with invertible 2-cells $\alpha: \text{id}_a \cong gf$ and $\beta: fg \cong \text{id}_b$.

From the point of view of 2-category theory, the most natural notion of “sameness” for a parallel pair of morphisms in a 2-category is isomorphism: $h, k: a \to b$ are to be regarded as the same if there exists an invertible 2-cell $\gamma: h \cong k$.

From the point of view of 2-category theory, the most natural notion of “sameness” for a pair of 2-cells with common boundary is equality. Because a 2-category lacks any higher dimensional morphisms to mediate between 2-cells, there is no weaker notion of sameness available.

Note that the data of an equivalence or isomorphism in a 2-category also defines an equivalence in each of its duals.

In Digression 1.2.4, we saw that the data of a simplicial category could be expressed as a diagram of a particular type valued in $\text{Cat}$. A small 2-category can be similarly encoded, in fact in two different ways, as a category defined internally to the category of categories.

B.1.8. Definition (internal category). Let $\mathcal{E}$ be any category with pullbacks. An internal category in $\mathcal{E}$ is given by the data

subject to commutative diagrams that define the domains and codomains of composites and identities

and encode the fact that composition is associative and unital.
An internal category in $\mathbf{Set}$ is an ordinary small category. An internal category in $\mathbf{Cat}$ defines a double category:

B.1.9. Definition (double-category). A double-category $\mathbf{C}$ is an internal category

$$
\begin{array}{ccc}
C_{h,s} \times C_{o,v} & \to & C_{h,s} \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
C_{o,v} & \leftarrow & C_{o,v}
\end{array}
$$

in $\mathbf{Cat}$. Explicitly it has:

- a category $C_{o,v}$ of objects and vertical arrows;
- a category $C_{h,s}$ of horizontal arrows and squares;
- functors $d, c: C_{h,s} \to C_{o,v}$ that assign a co/domain object to each horizontal arrow and a co/domain vertical arrow to each square;
- a functor $i: C_{o,v} \to C_{h,s}$ that assigns a horizontal identity arrow to each object and an identity square to each vertical arrow; and
- a composition functor $\circ: C_{h,s} \times C_{o,v} \to C_{h,s}$ that defines horizontal composition of horizontal arrows and squares that is functorial with respect to vertical composition in each variable.

A 2-category can be realized as a special case of this construction in the following two ways.

B.1.10. Digression (2-categories as category objects). A 2-category may be defined to be an internal category in $\mathbf{Cat}$

$$
\begin{array}{ccc}
C_{1,2} \times C_{0} & \to & C_{1,2} \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
C_{0} & \leftarrow & C_{0}
\end{array}
$$

in which the category $C_{0}$ is a set, namely the set of objects of the 2-category. The 1- and 2-cells occur as the objects and arrows of the category $C_{1,2}$. The functors $d, c: C_{1,2} \to C_{0}$ send 1- and 2-cells to their domain and codomain 0-cells. The functor $i: C_{0} \to C_{1,2}$ sends each object to its identity 1-cell. The action of the functor $\circ: C_{1,2} \times C_{0} \to C_{1,2}$ on objects defines composition of 1-cells and the action on morphisms defines the horizontal composition on 2-cells. Vertical composition on 2-cells is the composition inside the category $C_{1,2}$. Functoriality of this map encodes middle-four interchange. This definition motivates the Segal category model of $(\infty,1)$-categories described in Definition E.2.4.

Dually, a 2-category may be defined to be an internal category in $\mathbf{Cat}$

$$
\begin{array}{ccc}
C_{0,2} \times C_{0,1} & \to & C_{0,2} \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
C_{0,1} & \leftarrow & C_{0,1}
\end{array}
$$

in which the categories $C_{0,1}$ and $C_{0,2}$ have the same set of objects and all four functors are identity-on-objects. Here the common set of objects defines the objects of the 2-category and the arrows of $C_{0,1}$ and $C_{0,2}$ define the 1- and 2-cells, respectively. The functors $d, c: C_{1,2} \to C_{0,2}$ define the domain and codomain 1-cells for a 2-cell, which the functor $\circ: C_{0,2} \times C_{0,1} \to C_{0,2}$ encodes vertical composition of 2-cells. The composition inside the category $C_{0,2}$ defines horizontal composition of 2-cells. Functoriality of this map encodes middle-four interchange.

Exercises.

B.1.i. Exercise. Relate the structures itemized in Definition B.1.1 to the structures itemized in Definition A.2.1 in the case where the base for enrichment is $\mathbf{Cat}$. 

460
B.1.ii. Exercise. For any 2-category $\mathcal{C}$, define $\textbf{Cat}$-enriched categories $\mathcal{C}^{\text{op}}$, $\mathcal{C}^{\text{co}}$, and $\mathcal{C}^{\text{coop}}$ along the lines specified by Definition B.1.6.

B.1.iii. Exercise. Define a duality involution on double categories that exchanges the two expressions of a 2-category as an internal category appearing in Digression B.1.10.

B.2. The 3-Category of 2-Categories

Ordinary 1-categories form the objects of a 2-category of categories, functors, and natural transformations. Similarly, 2-categories form the objects of a 3-category of 2-categories, 2-functors, 2-natural transformations, and modifications. In this section, we briefly introduce all of these notions.

Recall from Definition B.1.1, that a 2-category is a category enriched in $\textbf{Cat}$. Similarly, 2-functors and 2-natural transformations are precisely the $\textbf{Cat}$-enriched functors and $\textbf{Cat}$-enriched natural transformations of Appendix A. By Corollary A.3.6, 2-categories, 2-functors, and 2-natural transformations assemble into a 2-category. The 3-dimensional cells between 2-categories — the modifications — are defined using the 2-cells of a 2-category, like the 2-dimensional cells between 1-categories — the natural transformations — are defined using the 1-cells in a 1-category.

B.2.1. Definition. A 2-functor $F: \mathcal{C} \to \mathcal{D}$ between 2-categories is given by:

- a mapping on objects $\mathcal{C} \ni x \mapsto Fx \in \mathcal{D};$
- a functorial mapping on 1-cells $\mathcal{C} \ni f: x \to y \mapsto Ff: Fx \to Fy \in \mathcal{D}$ respecting domains and codomains; and
- a mapping on 2-cells

$$
\mathcal{C} \ni x \xrightarrow{\alpha} y \quad \mapsto \quad Fx \xrightarrow{F\alpha} Fy \quad \in \mathcal{D}
$$

that respects 0- and 1-cell sources and targets that is functorial for both horizontal and vertical composition and horizontal and vertical identities.

B.2.2. Definition. A 2-natural transformation $\mathcal{C} \xrightarrow{\phi} \mathcal{D}$ between a parallel pair of 2-functors $F$ and $G$ is given by a family of 1-cells $(\phi_c: Fc \to Gc)_{c \in \mathcal{C}}$ in $\mathcal{D}$ indexed by the objects of $\mathcal{C}$ that are natural with respect to the 1-cells $f: x \to y$ in $\mathcal{C}$, in the sense that the square

$$
\begin{array}{ccc}
Fx & \xrightarrow{Ff} & Fy \\
\phi_x \downarrow & & \downarrow \phi_y \\
Gx & \xrightarrow{Gf} & Gy
\end{array}
$$
commutes in $\mathcal{D}$, and also natural with respect to the 2-cells $\xymatrix{ x \ar[r]^-f \ar@/_/[r]_-{\phi_a}_-g & y}$ in $\mathcal{C}$, in the sense that the whiskered composites $\phi_y \cdot F\alpha$ and $G\alpha \cdot \phi_x$ are equal:

\[
\begin{array}{ccc}
Fx & \xymatrix{ Fx \ar[r]^-{\phi_x} & Gx } & \xymatrix{ Fy \ar[r]^-{\phi_y} & Gy } \\
\xymatrix{ Gx \ar@/_/[r]_-{G\alpha}_-Gg & Gy }
\end{array}
\]

The 3-dimensional morphisms between 2-categories are outside the purview of $\text{Cat}$-enriched category theory:

**B.2.3. Definition.** A **modification** $\Xi : \phi \Rightarrow \psi$

between parallel 2-natural transformations is given by a family of 2-cells in $\mathcal{D}$

\[
\begin{array}{ccc}
F \ar@/^/[r]^-F \ar@/_/[r]_-G & C \ar@/^/[r]^-c \ar@/_/[r]_-G & D \\
\xymatrix{ F \ar[r]^-{\phi_c} & Gc } & \xymatrix{ \Xi_c \ar@/^/[r]^-{\Xi_c} & \psi_c } & \xymatrix{ D }
\end{array}
\]

indexed by the objects $c \in \mathcal{C}$ with the property that for any 1-cell $f : x \to y$ in $\mathcal{C}$, the whiskered composites $\Xi_y \cdot Ff = Gf \cdot \Xi_x$ are equal in $\mathcal{D}$ and for any 2-cell $\alpha : f \Rightarrow g$ in $\mathcal{D}$, the horizontal composites in $\mathcal{D}$

\[
\begin{array}{ccc}
Fx & \xymatrix{ Fx \ar[r]^-{\phi_x} & Gx } & \xymatrix{ Gy \ar[r]^-{\phi_y} & Gy } \\
\xymatrix{ Fy \ar@/_/[r]_-{F\alpha}_-Fg & Gx } & \xymatrix{ G \ar@/_/[r]_-{G\alpha}_-Gg & Gy }
\end{array}
\]

are equal.

Finally, the category of 2-categories is cartesian closed, with internal hom $\mathbf{B}^\mathbf{A}$ defined to be the 2-category of 2-functors, 2-natural transformations, and modifications. So now we can define a **3-category** to be a category enriched in 2-categories.

**B.2.4. Corollary.** There is a 3-category $\textbf{2-Cat}$ of 2-categories, 2-functors, 2-natural transformations, and modifications.

**Proof.** Lemma A.2.3 proves that any cartesian closed category is enriched over itself. Thus $\textbf{2-Cat}$ defines a 3-category. $\square$
Exercises.

B.2.i. Exercise. Relate the structures itemized in Definitions B.2.1 and B.2.2 to the structures itemized in Definition A.2.5 and A.3.2 in the case where the base for enrichment is $\mathbf{Cat}$.

B.2.ii. Exercise. For the reader who has a large writing surface, unpack the definition of a 3-category just given.

B.2.iii. Exercise.

(i) Show that the functor that sends a 1-category to its opposite defines an involutive 2-functor $(-)^{\text{op}} : \mathbf{Cat}^{\text{co}} \to \mathbf{Cat}$ on the 2-category of categories, functors, and natural transformations.

(ii) Similarly the functors that send a 2-category to one of its three duals can be understood as involutions of the 3-category of 2-categories, 2-functors, 2-natural transformations, and modifications. What is the variance of each of these mappings?

B.3. Adjunctions and Mates

As discussed in Chapter 2, any 2-category has an internally-defined notion of adjunction, comprised of:

- a pair of objects $a$ and $b$,
- a pair of 1-cells $u : a \to b$ and $f : b \to a$, and
- a pair of 2-cells $\eta : 1_b \Rightarrow uf$ and $\epsilon : fu \Rightarrow 1_a$, called the unit and counit respectively,

so that the triangle equalities hold:

$$
\begin{array}{c}
a \xrightarrow{u} b \\
\downarrow \eta \\
b \xrightarrow{f} a
\end{array}
\quad = 
\begin{array}{c}
b \xrightarrow{uf} b \\
\downarrow \eta u \\
a \xrightarrow{u} a
\end{array}
\quad = 
\begin{array}{c}
a \xrightarrow{f} a \\
\downarrow \eta f \\
b \xrightarrow{1_a} b
\end{array}
\quad = 
\begin{array}{c}
a \xrightarrow{f} a \\
\downarrow \epsilon \\
b \xrightarrow{1_b} b
\end{array}
\quad = 
\begin{array}{c}
b \xrightarrow{1_b} b \\
\downarrow \epsilon u \\
a \xrightarrow{u} a
\end{array}
$$

The 1-cell $f$ is called the left adjoint and $u$ is called the right adjoint, a relationship that is denoted symbolically in text by writing $f \dashv u$ or in a displayed diagram such as

$$
\begin{array}{c}
a \xrightarrow{f} b
\end{array}
\quad \leftrightarrow 
\begin{array}{c}
\bot \quad b \xleftarrow{u} a
\end{array}
\quad (B.3.1)
$$

The basic 2-category theory of adjunctions is developed in §2.1, whose results specialize to prove theorems about adjunctions between $\infty$-categories. Here we extend that theory in a complementary direction by developing the calculus of mates, which generalize the more familiar notion of adjoint transposes.

In the presence of an adjunction as in (B.3.1), certain 2-cells with codomain $a$ “transpose” into 2-cells with codomain $b$; op-dually, certain 2-cells with domain $a$ “transpose” into 2-cells with domain $b$: for any 1-cells $w \xleftarrow{x} b$, $w \xrightarrow{y} a$, $a \xrightarrow{h} z$, and $b \xrightarrow{k} z$

$$
\begin{array}{c}
fx \xrightarrow{a} y \\
\leftrightarrow \\
x \xrightarrow{b} uy \\
\leftrightarrow \\
hf \xrightarrow{y} k \\
\leftrightarrow \\
h \xrightarrow{\delta} ku
\end{array}
\quad (B.3.2)
$$

Both of these transposition operations admit a common generalization due to Kelly and Street [68] referred to as the “mates correspondence” which describes a duality between 2-cells induced by a pair of adjunctions.
B.3.3. Definition (mates). Given any pair of adjunctions and functors

\[
\begin{array}{c}
\begin{array}{c}
 b \\
 f \\
 a
\end{array}
\xrightarrow{\begin{array}{c}
k\\
\alpha
\end{array}}
\begin{array}{c}
b' \\
\downarrow f' \\
\downarrow \beta
\end{array}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\xleftarrow{\begin{array}{c}
f \\
\downarrow \alpha
\end{array}}
\begin{array}{c}
\begin{array}{c}
a \\
\downarrow h
\end{array}
\xrightarrow{\begin{array}{c}
k'\\
\beta
\end{array}}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\end{array}
\]

there is exists a bijection between 2-cells as below-left and 2-cells as below-right

\[
\begin{array}{c}
\begin{array}{c}
b \\
\downarrow f \\
\downarrow \alpha
\end{array}
\xrightarrow{\begin{array}{c}
k\\
\downarrow \alpha
\end{array}}
\begin{array}{c}
b' \\
\downarrow f' \\
\downarrow \beta
\end{array}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\xleftarrow{\begin{array}{c}
f \\
\downarrow \alpha
\end{array}}
\begin{array}{c}
\begin{array}{c}
a \\
\downarrow h
\end{array}
\xrightarrow{\begin{array}{c}
k'\\
\downarrow \beta
\end{array}}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\end{array}
\]

implemented by pasting with the units and counits of the adjunctions:

\[
\begin{array}{c}
\begin{array}{c}
b \\
\downarrow f \\
\downarrow \alpha
\end{array}
\xrightarrow{\begin{array}{c}
k\\
\downarrow \alpha
\end{array}}
\begin{array}{c}
b' \\
\downarrow f' \\
\downarrow \beta
\end{array}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\xleftarrow{\begin{array}{c}
f \\
\downarrow \alpha
\end{array}}
\begin{array}{c}
\begin{array}{c}
a \\
\downarrow h
\end{array}
\xrightarrow{\begin{array}{c}
k'\\
\downarrow \beta
\end{array}}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\end{array}
\]

Pairs of corresponding 2-cells (B.3.4) under this bijection are referred to as mates.

B.3.5. Example. The mates correspondence specializes to define a bijection between 2-cells between a parallel pair of left adjoints and 2-cells pointing in the opposite direction between their right adjoints that Mac Lane refers to as conjugates [79, §IV.7]:

\[
\begin{array}{c}
\begin{array}{c}
b \\
\downarrow f\alpha
\end{array}
\xrightarrow{\begin{array}{c}
k\\
\downarrow \alpha
\end{array}}
\begin{array}{c}
b' \\
\downarrow f' \\
\downarrow \beta
\end{array}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\xleftarrow{\begin{array}{c}
f \\
\downarrow \alpha
\end{array}}
\begin{array}{c}
\begin{array}{c}
a \\
\downarrow h
\end{array}
\xrightarrow{\begin{array}{c}
k'\\
\downarrow \beta
\end{array}}
\begin{array}{c}
a' \\
\downarrow u' \\
\downarrow \eta'
\end{array}
\end{array}
\]

The mates correspondence is respected by horizontal and vertical composition of squares (B.3.4) in the sense made precise by the following result:

B.3.6. Theorem (double-functoriality of the mates correspondence). For any 2-category \( \mathcal{C} \), there is an identity on objects, vertical morphisms, and horizontal morphisms, double isomorphism \( \mathbb{Ladj}(\mathcal{C}) \cong \mathbb{Radj}(\mathcal{C}) \) between the double categories whose

- objects and horizontal morphisms are the objects and 1-cells of \( \mathcal{C} \)
- vertical morphisms are fully-specified adjunctions \((f, u, \eta, \epsilon)\) pointing in the direction of the left adjoint
• cells in \( \mathbb{L} \text{adj} \) are 2-cells in \( \mathcal{C} \) of the form displayed below-left, while cells in \( \mathbb{R} \text{adj} \) are 2-cells in \( \mathcal{C} \) of the form displayed below-right:

\[
\begin{array}{c}
\begin{array}{ccc}
  b & \xrightarrow{k} & b' \\
  f & \downarrow & \downarrow f' \\
  a & \xrightarrow{h} & a'
\end{array}
\end{array}
\quad \begin{array}{c}
\begin{array}{ccc}
  b & \xrightarrow{k} & b' \\
  u & \downarrow & \downarrow u' \\
  a & \xrightarrow{h} & a'
\end{array}
\end{array}
\]

that acts on cells by taking mates.

Note that the composition of vertical morphisms in the double categories \( \mathbb{L} \text{adj} \) and \( \mathbb{R} \text{adj} \) makes use of Proposition 2.1.9.

**Proof.** The horizontal and vertical functoriality of the mates correspondence of Definition B.3.3 can be verified by a pasting diagram chase, or see [68, 2.2]. \( \square \)

**B.3.7. Warning (mates of isomorphisms need not be isomorphisms).** In general it is possible for one of the 2-cells in a mate pair (B.3.4) to be invertible without the other being so. For instance, the unit and counit of an adjunction \( f \dashv u \) are each mates with both the identity cells \( \text{id}_f \) and \( \text{id}_u \), depending on which way these 2-cells are arranged to fit in squares; see Exercise B.3.i. However if both horizontal 1-cells \( a \) and \( b \) are equivalences, or if both adjunctions \( f \dashv u \) are adjoint equivalences \( f' \dashv u' \), then \( \alpha: f'b \Rightarrow af \) is invertible if and only if its mate \( \beta: bu \Rightarrow u'a \) is invertible.

Elaborating upon Warning B.3.7 we have:

**B.3.8. Proposition (equivalence invariance of adjointness).** Suppose given an essentially commutative square whose horizontal arrows are equivalences:

\[
\begin{array}{c}
\begin{array}{ccc}
  b & \xrightarrow{k} & b' \\
  u & \downarrow & \downarrow u' \\
  a & \xrightarrow{h} & a'
\end{array}
\end{array}
\quad \begin{array}{c}
\begin{array}{ccc}
  b & \xrightarrow{k} & b' \\
  u & \downarrow & \downarrow u' \\
  a & \xrightarrow{h} & a'
\end{array}
\end{array}
\]

Then \( f \) admits a right adjoint \( u \) if and only \( f' \) admits a right adjoint \( u' \), in which case the mate of the isomorphism \( \alpha \) is an isomorphism.

**Proof.** Proposition 2.1.12 may be used to choose inverse adjoint equivalences \( k' \dashv k \) and \( h' \dashv h \). If \( f \) is a left adjoint, then by Proposition 2.1.9, \( f' \cong hfk' \) is isomorphic to a left adjoint, and so by Proposition 2.1.10 \( f' \) is left adjoint to \( kuh' \). If \( f' \dashv u' \) is defined to be the composite adjunction as in the previous paragraph, the mate of \( \alpha \) works out to the whiskered composite of \( h'h \cong \text{id}_a \) with \( ku \). By Proposition 2.1.10, any other choice of right adjoint to \( f' \) is isomorphic to this one, so the mate of \( \alpha \) is still an isomorphism. \( \square \)

Exercise B.3.ii suggests a new proof that any pair of left adjoints \( f' \dashv u \) and \( f \dashv u \) to a common 1-cell are isomorphic by applying the double isomorphism \( \mathbb{L} \text{adj} \cong \mathbb{R} \text{adj} \). A more complicated argument along the same lines can be used to prove:

**B.3.9. Lemma.** Suppose given a triple of adjoint functors \( \ell \dashv i \dashv r \). Then the counit of \( \ell \dashv i \) is invertible if and only if the unit of \( i \dashv r \) is invertible.

465
Proof. Let \( i : a \to b \) and write \( e : \ell i \Rightarrow \text{id}_a \) for the counit of \( \ell \dashv i \) and \( \eta : \text{id}_a \Rightarrow ri \) for the unit of \( i \dashv r \). If \( e \) admits an inverse isomorphism \( e^{-1} : \ell i \Rightarrow \text{id}_a \), then the vertical composite in \( \text{LAdj} \)

\[
\begin{array}{ccc}
\text{a} & \xrightarrow{\ell i} & \text{b} \\
\downarrow{\ell i} \downarrow{\eta} & & \downarrow{\ell i} \\
\text{a} & \xrightarrow{i} & \text{b} \\
\downarrow{\ell} \downarrow{\eta} & & \downarrow{\ell} \\
\text{a} & \xrightarrow{\text{id}} & \text{a}
\end{array}
\]

admits an inverse cell for horizontal composition in \( \text{LAdj} \):

\[
\begin{array}{ccc}
\text{a} & \xrightarrow{\ell i} & \text{a} \\
\downarrow{\ell i} \downarrow{\text{id}} & & \downarrow{\ell i} \\
\text{a} & \xrightarrow{i} & \text{a} \\
\downarrow{\ell} \downarrow{\text{id}} & & \downarrow{\ell} \\
\text{a} & \xrightarrow{\text{id}} & \text{a}
\end{array}
\]

Applying the horizontal functoriality of the double isomorphism \( \text{LAdj} \cong \text{RAdj} \), the mates of these cells must also compose horizontally in \( \text{RAdj} \) to identities.\(^1\) Applying the vertical functoriality of the double isomorphism \( \text{LAdj} \cong \text{RAdj} \), the mate of the vertical composite equals the composite

\[
\begin{array}{ccc}
\text{a} & \xrightarrow{\ell i} & \text{a} \\
\downarrow{\ell i} \downarrow{\text{id}} & & \downarrow{\ell i} \\
\text{a} & \xrightarrow{i} & \text{a} \\
\downarrow{\ell} \downarrow{\text{id}} & & \downarrow{\ell} \\
\text{a} & \xrightarrow{\eta^{-1}} & \text{a}
\end{array}
\]

in \( \text{RAdj} \). In summary, we conclude that the counit of \( \ell \dashv i \) is an isomorphism if and only if the unit of \( i \dashv r \) is an isomorphism, in which case its inverse isomorphism \( \eta^{-1} : ri \Rightarrow \text{id}_a \) is the mate of \( e^{-1} : \text{id}_a \Rightarrow \ell i \) via the composite adjunction \( \ell i \dashv ri \):

\[
\begin{array}{ccc}
\text{a} & \xrightarrow{\ell i} & \text{a} \\
\downarrow{\ell i} \downarrow{\eta^{-1}} & & \downarrow{\ell i} \\
\text{a} & \xrightarrow{i} & \text{a} \\
\downarrow{\ell} \downarrow{\eta^{-1}} & & \downarrow{\ell} \\
\text{a} & \xrightarrow{\text{id}} & \text{a}
\end{array}
\]

Exercises.

B.3.i. Exercise.

(i) Explain how the bijections (B.3.2) may be realized as special cases of the mates correspondence.

(ii) By choosing a suitable pair of adjunctions and functors, explain how the unit of an adjunction \( f \dashv u \) is mates with \( \text{id}_u \).

(iii) By choosing a suitable pair of adjunctions and functors, explain how the unit of an adjunction \( f \dashv u \) is mates with \( \text{id}_f \).

B.3.ii. Exercise. Consider two adjunctions \( f \dashv u \) and \( f' \dashv u \) as vertical morphisms in \( \text{LAdj} \cong \text{RAdj} \) and apply the double functoriality of the mates correspondence to prove that \( f \cong f' \).\(^1\)

\(^1\)Since the horizontal morphisms in the cells in question are all identities, the concern raised in Warning B.3.7 does not apply.
B.3.iii. Exercise. Consider a 2-cell

\[
\begin{array}{c@{\,\rightarrow\,}c}
B & B' \\
\downarrow f & \downarrow f' \\
A & A'
\end{array}
\]

in which the vertical 1-cells admit right adjoints \( f \dashv u \) and \( f' \dashv u' \) and the horizontal 1-cells admit left adjoints \( \ell \dashv r \) and \( \ell' \dashv r' \). Show that the mate of \( \alpha \) with respect to the vertical adjunctions defines an isomorphism \( ru \cong u'r' \) if and only if the mate of \( \alpha \) with respect to the horizontal adjunctions defines an isomorphism \( \ell'f' \cong \ell f \)—and these isomorphisms are themselves mates in the sense of Example B.3.5 with respect to the composite adjunctions.

B.3.iv. Exercise. Show that any 2-functor \( F : C \to D \) preserves equivalences, adjunctions, and mates. Indeed, the isomorphism of double categories of Theorem B.3.6 can be regarded as defining a component of a 2-natural isomorphism between 2-functors \( \text{Ladj, Radj} : 2\text{-Cat} \to \text{Dbl-Cat} \) from \( 2\text{-Cat} \) to the 2-category of double categories, double functors, and horizontal natural transformations.

B.4. Right Adjoint Right Inverse Adjunctions

An important class of adjunctions is those whose counit 2-cells are isomorphisms.

B.4.1. Definition. A 1-cell \( f : b \to a \) in a 2-category admits a right adjoint right inverse, abbreviated \( \text{RARI} \), if it admits a right adjoint \( u : a \to b \) so that the counit of the adjunction \( f \dashv u \) is an isomorphism.

In the situation of Definition B.4.1, \( f \) defines a left adjoint left inverse, abbreviated \( \text{LALI} \), to \( u \). The co-dual defines the class left adjoint right inverse or right adjoint left inverse adjunctions with invertible unit, \( \text{LARIs} \) and \( \text{RALIs} \) for short. We leave the dualizations of the results that follow to the reader.

When the counit of \( f \dashv u \) is an isomorphism, the whiskered composites \( f\eta \) and \( \eta u \) of the unit must also be isomorphisms. Indeed, to construct an adjunction of this form it suffices to give 2-cells with these properties, as demonstrated by the following 2-categorical lemma.

B.4.2. Lemma. Suppose we are given a pair of 1-cells \( u : a \to b \) and \( f : b \to a \) and a 2-isomorphism \( f u \cong id_a \) in a 2-category. If there exists a 2-cell \( \eta' : id_b \Rightarrow uf \) with the property that \( f\eta' \) and \( \eta'u \) are 2-isomorphisms, then \( f \) is left adjoint to \( u \). Furthermore, in the special case where \( u \) is a section of \( f \), then \( f \) is left adjoint to \( u \) with the counit of the adjunction an identity.

Since \( f\eta' \) and \( \eta'u \) are isomorphisms and \( fu \cong id_u \), the “triangle equality composites” of Lemma 2.1.11 are invertible, so from that result we can conclude that \( f \dashv u \). Indeed, from the construction given in that proof, we see that we can take the specified isomorphism \( fu \cong id_u \) to be the counit of the adjunction, so in particular when \( u \) is a section of \( f \) this counit may be taken to be the identity. The direct proof given below compiles out the argument just sketched.

Proof. Let \( e : fu \Rightarrow id_u \) be the isomorphism, taken to be the identity in the case where \( u \) is a section of \( f \). We will define an adjunction \( f \dashv u \) with counit \( e \) by modifying \( \eta' : id_b \Rightarrow uf \). The “triangle identity composite” \( \Theta := ue \cdot \eta'u : u \Rightarrow u \) defines an automorphism of \( u \). Define

\[
\begin{align*}
\eta &:= id_b \\
\eta' &\Rightarrow uf \\
\theta &:= (uf)^{-1}\\
\Theta &:= id_b \\
(\eta'u) &\Rightarrow uf \\
\Theta &\Rightarrow uf(\eta'u)^{-1} \\
\eta &\Rightarrow uf.
\end{align*}
\]

467
Immediately, $u \cdot \eta u = \text{id}_u$, as is verified by the calculation:

\[
\begin{array}{ccc}
u & \xrightarrow{\eta u} & u f u \\
\downarrow & & \downarrow_{\theta f u} \\
u & \xrightarrow{\theta^{-1}} & u
\end{array}
\]

The other triangle identity composite $\phi := e f \cdot f \eta$ is an isomorphism, as a composite of isomorphisms, and also an idempotent:

\[
\begin{array}{ccccccccc}
f & \xrightarrow{f \eta} & f u f & \xrightarrow{e f} & f \\
\downarrow_{f \eta} & & \downarrow_{f u f \eta} & & \downarrow_{f \eta} \\
f u f & \xrightarrow{f u f \eta} & f u f & \xrightarrow{e f u f} & f u f & \xrightarrow{e f} & f
\end{array}
\]

By cancelation, any idempotent isomorphism is the identity, proving that $e f \cdot f \eta = \text{id}_f$. □

A generalized element $y : z \to b$ is said to be in the essential image of a 1-cell $u : a \to b$ if there exists a generalized element $x : z \to a$ and an invertible 2-cell $\beta : y \cong u x$. When the functor $u$ is right adjoint right inverse to $f$, there is a convenient characterization of its essential image:

**B.4.3. LEMMA.** A generalized element $y : z \to b$ is in the essential image of the right adjoint $u : a \to b$ of a RARI if and only if the unit component $\eta y : y \Rightarrow u f y$ is an isomorphism.

**PROOF.** It remains only to argue that if given an invertible 2-cell $\beta : y \cong u x$, the unit component $\eta y$ is also an isomorphism. This follows immediately from the banal final statement of Lemma B.1.3. From the horizontally-composable pair

\[
\begin{array}{ccc}
z & \xrightarrow{y} & b \\
\downarrow & & \downarrow_{f} \\
a & \xrightarrow{u} & a
\end{array}
\]

we get a commutative diagram

\[
\begin{array}{c}
y \xrightarrow{\eta y} u f y \\
\downarrow_{\beta} \cong \downarrow_{\beta} \\
ux \xrightarrow{\eta u x} u f u x
\end{array}
\]

and $f \dashv u$ is a RARI, $\eta u$ is invertible. Thus, if $\beta$ is invertible so is $\eta y$. □

Sometimes it is more convenient to make use of a stricter notion of RARI, in which the counit $e$ is required to be the identity $f u = \text{id}_u$. In this case it follows from the triangle equalities that $f \eta = \text{id}_f$, so that the unit is fibered over $a$. 

468
When the left adjoint has a 2-categorical property that we now introduce, we shall see that a right adjoint right inverse up to isomorphism can always be replaced by a right adjoint right inverse up to identity.

B.4.4. **Definition** (isofibration). A 1-cell \( f : b \to a \) in a 2-category defines an **isofibration** — in which case the arrow is typically denoted by “\( \rightarrow \)” — if given any invertible 2-cell \( \alpha : f y \cong x \) abutting to \( a \) with a specified lift of one of its boundary 1-cells through \( f \), there exists an invertible 2-cell \( \beta : y \cong \tilde{y} \) abutting to \( b \) with this boundary 1-cell that whiskers with \( f \) to the original 2-cell:

\[
\begin{array}{c}
z \xrightarrow{\gamma} b \\
\downarrow_{\alpha} \ \\
x \xrightarrow{f} a
\end{array}
\]

### B.4.5. **Lemma.** Let \( f : b \to a \) be any isofibration in a 2-category \( C \) that admits a right adjoint \( u' : a \to b \) with counit \( \epsilon : fu' \cong \text{id}_a \) an isomorphism. Then \( u' \) is isomorphic to a functor \( u \) that lies strictly over \( a \) and defines a strict right adjoint right inverse to \( f \). Thus any such \( f \) defines an adjunction

\[
\begin{array}{c}
f \\
\downarrow \\
b \xrightarrow{u} a
\end{array}
\]

in the 2-category \( C_{/a} \) of isofibrations with codomain \( a \), commutative triangles over \( a \), and 2-cells that whisker to identities abutting to \( a \).

**Proof.** Define the 1-cell \( u : a \to b \) by lifting the counit isomorphism through the isofibration \( f : b \to a \)

\[
\begin{array}{c}
a \xrightarrow{u'} b \\
\downarrow_{\epsilon} \ \\
\downarrow_{f} \ \\
a \xrightarrow{u} a
\end{array}
\]

Note by construction that \( fu = \text{id}_a \), so \( u \) defines a 1-cell in \( C_{/a} \). By the triangle equalities for the adjunction \( f \dashv u' \), the unit defines a 2-cell \( \eta : \text{id}_b \Rightarrow u'f \) with \( \eta u' \) and \( fu \eta \) both invertible. The composite 2-cell

\[
\eta' := \text{id}_b \xrightarrow{\eta} u'f \xrightarrow{\beta f} uf
\]

lies in \( C_{/a} \) has the properties that \( \eta' u \) and \( f \eta \) are both invertible. Applying Lemma B.4.2 in the 2-category \( C_{/a} \), this 2-cell may then be modified to define the unit of an adjunction \( f \dashv u \) with counit \( fu = \text{id}_a \).

**Exercises.**

B.4.i. **Exercise.** Consider a pair of equivalent adjunctions, satisfying the condition of Proposition B.3.8. Show that if either of these adjunctions is a RARI, then both are.
B.5. Absolute Absolute Lifting Diagrams

Recall from Definition 2.3.4 that for any cospan \( c \xrightarrow{g} a \leftarrow f \xleftarrow{b} \) in a 2-category, an absolute right lifting of \( g \) through \( f \) is given by a 1-cell \( r \) and 2-cell \( \rho \) as displayed below-left

\[
\begin{array}{ccc}
  r & \Rightarrow & b \\
  \downarrow & & \downarrow f \\
  c & \Rightarrow & a \\
 \end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  \downarrow y & & \downarrow f \\
  c & \xrightarrow{g} & a \\
\end{array}
\]

so that any 2-cell as displayed above-center factors uniquely through \((r, \rho)\) as displayed above-right. The adjective “absolute” refers to the property that absolute right lifting diagrams are stable under whiskering with any 1-cell \( k: d \to c \).

The following lemma yields absolute right lifting diagrams which are absolute in a second sense: namely, they are preserved by any 2-functor.

B.5.1. Lemma. Suppose \((f \dashv u, \eta: \text{id}_a \to uf, \epsilon: fu \to \text{id}_c)\) is an adjunction under \( b \) in the sense that

- the solid-arrow triangles involving both adjoints commute

\[
\begin{array}{ccc}
  r & \Rightarrow & b \\
  \downarrow & & \downarrow f \\
  c & \Rightarrow & a \\
\end{array}
\]

- and \( \eta a = \text{id}_a \) and \( \epsilon c = \text{id}_c \)

Then if \( \ell \) admits a right adjoint \( r \) with unit \( \iota: \text{id}_b \Rightarrow r \ell \) and counit \( \nu: \ell r \Rightarrow \text{id}_c \), then \( uv \) exhibits \( r \) as an absolute right lifting of \( u \) through \( k \).

Proof. The argument is purely diagrammatic. Any 2-cell as below-left factors through \( uv \) as below-right:

\[
\begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \chi & \downarrow k \\
  c & \xrightarrow{u} & a \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \chi & \downarrow k \\
  c & \xrightarrow{u} & a \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \chi & \downarrow k \\
  c & \xrightarrow{u} & a \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \chi & \downarrow k \\
  c & \xrightarrow{u} & a \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \chi & \downarrow k \\
  c & \xrightarrow{u} & a \\
\end{array}
\]

Conversely, if \( \zeta \) defines a factorization of \( \chi \) through \( uv \), then

\[
\begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \zeta \chi & \downarrow r \\
  c & \xrightarrow{r} & e \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \zeta \chi & \downarrow r \\
  c & \xrightarrow{r} & e \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \zeta \chi & \downarrow r \\
  c & \xrightarrow{r} & e \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \zeta \chi & \downarrow r \\
  c & \xrightarrow{r} & e \\
\end{array}
\quad \begin{array}{ccc}
  z & \xrightarrow{x} & b \\
  y & \downarrow \zeta \chi & \downarrow r \\
  c & \xrightarrow{r} & e \\
\end{array}
\]

470
proving that the factorization constructed above is unique.

\[ \begin{array}{cccc}
  z & \xrightarrow{x} & b & \xrightarrow{r} b \\
  \downarrow \gamma_c & & \downarrow \gamma_r & \downarrow \gamma_r \\
  c & \xrightarrow{a} & b & \xrightarrow{f} c \\
\end{array} \]

\[ \begin{array}{cccc}
  z & \xrightarrow{x} & b & \xrightarrow{r} b \\
  \downarrow \gamma_c & & \downarrow \gamma_r & \downarrow \gamma_r \\
  c & \xrightarrow{a} & b & \xrightarrow{f} c \\
\end{array} \]

B.5.2. EXAMPLE. For example, there is a diagram of adjoint functors

\[ \begin{array}{cccc}
  \Delta & \xleftarrow{\dashv} & \Delta_+ & \xrightarrow{\dashv} \Delta_1 \\
  \downarrow \gamma & & \downarrow \gamma & \downarrow \gamma \\
  \downarrow \gamma & & \downarrow \gamma & \downarrow \gamma \\
\end{array} \]

involving the categories introduced in Definition 2.3.11. The inclusion \( \Delta \hookrightarrow \Delta_+ \hookrightarrow \Delta_1 \) freely adjoins a bottom element to each ordinal, while its right adjoint can be identified with the inclusion \( \Delta_1 \hookrightarrow \Delta \) of the wide subcategory whose morphisms are bottom-element preserving maps. The adjunction \( [-1] \dashv ! \) witnesses the fact that \( [-1] \in \Delta_1 \) defines an initial object with the counit \( \nu \) defining the canonical natural transformation from the initial object to the identity functor.

This diagram satisfies the premises of Lemma B.5.1 in \( \mathcal{C}at^{\text{op}} \). Let \( a \) be an object of any 2-category \( \mathcal{C} \) that is cotensored over \( \mathcal{C}at \). Then the 2-functor \( a^{(-)} : \mathcal{C}at^{\text{op}} \to \mathcal{C} \) carries the given data to a diagram of adjoint functors in \( \mathcal{C} \) as below-left and hence the triangle below-right is absolute right lifting:

\[ \begin{array}{cccc}
  a^{\Delta_+} & \xrightarrow{ev_1} & a & \xrightarrow{\Delta} \\
  \downarrow \Delta & & \downarrow \Delta & \downarrow \Delta \\
  a^{\Delta_1} & \xrightarrow{\Delta} & a & \xrightarrow{\Delta} \\
\end{array} \]

This proves Proposition 2.3.13.

B.5.3. EXAMPLE. There is a similar diagram of adjoint functors

\[ \begin{array}{cccc}
  \Delta & \xleftarrow{\dashv} & \Delta_+ & \xrightarrow{\dashv} \Delta_+ \\
  \downarrow \gamma & & \downarrow \gamma & \downarrow \gamma \\
  \downarrow \gamma & & \downarrow \gamma & \downarrow \gamma \\
\end{array} \]

again involving the categories introduced in Definition 2.3.11. The inclusion \( \Delta \hookrightarrow \Delta_+ \hookrightarrow \Delta_+ \) freely adjoins a top element and its right adjoint can be identified with the inclusion \( \Delta_+ \hookrightarrow \Delta \) of the wide subcategory whose morphisms are top-element preserving maps. The adjunction \( [-1] \dashv ! \) witnesses the fact that \( [-1] \in \Delta_+ \) defines an initial object with the counit \( \nu \) defining the canonical natural transformation from the initial object to the identity functor. This proves another version of Proposition 2.3.13 where the “splittings” occur on the other side of the co/simplicial objects.

Exercises.

B.5.i. EXERCISE. Search for other diagrams in \( \mathcal{C}at \) satisfying the premises of Lemma B.5.1, such as the example implicit in Exercise 2.3.iv.
B.6. Representable Characterizations of 2-Categorical Notions

In the cartesian closed category of 2-categories, the hom 2-functor \( \mathcal{C}(\cdot,\cdot) : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{Cat} \) associated to any 2-category \( \mathcal{C} \) transposes to define a Yoneda embedding 2-functor \( \mathcal{Y} : \mathcal{C}^{\text{op}} \hookrightarrow \mathcal{Cat} \) whose codomain is the 2-category of 2-functors, 2-natural transformations, and modifications from \( \mathcal{C} \) to \( \mathcal{Cat} \). By the enriched Yoneda lemma, this 2-functor is fully faithful in an enriched sense: the 2-category \( \mathcal{C} \) is isomorphic to the full sub 2-category spanned by the representable 2-functors \( \mathcal{C}(x,\cdot) : \mathcal{C} \to \mathcal{Cat} \).

On account of this enriched fully-faithfulness, structures such as equivalences or adjunctions that are defined internally to the 2-category \( \mathcal{C} \) are both preserved and reflected by the Yoneda embedding.

This result is less useful than one might expect. Indeed, none of the “representable characterizations” of equivalences, adjunctions, and absolute lifting diagrams proven in this section are consequences of it. The main point is that the 1-cells in \( \mathcal{Cat}^{\mathcal{C}} \) are 2-natural transformations, but as our proofs will reveal, weaker naturality conditions suffice to detect 2-categorical structures that exist in \( \mathcal{C} \). We will have more to say about the Yoneda perspective in Remark B.6.7 at the close of this section.

Recall from Definition 1.4.6 that an equivalence in a 2-category is given by:

- a pair of objects \( a \) and \( b \)
- a pair of 1-cells \( f : a \to b \) and \( g : b \to a \)
- a pair of invertible 2-cells

\[
\begin{array}{ccc}
a & \overset{\cong}{\Rightarrow} & a \\
gf & \downarrow & \\
b & \cong \Rightarrow & b
\end{array}
\]

By analogy with Theorem 1.4.7, we have the following result which tells us that equivalences in a 2-category represent equivalences of categories.

**B.6.1. PROPOSITION (equivalences are representably defined).** A 1-cell \( f : a \to b \) in a 2-category \( \mathcal{C} \) defines an equivalence if and only if for all \( x \in \mathcal{C} \) the induced functor

\[
\mathcal{C}(x,a) \xrightarrow{f_*} \mathcal{C}(x,b)
\]

defines an equivalence of categories.

**PROOF.** Each \( x \in \mathcal{C} \) defines a 2-functor \( \mathcal{C}(x,-) : \mathcal{C} \to \mathcal{Cat} \), so if \( f : a \Rightarrow b \) is an equivalence in \( \mathcal{C} \), then \( f_* : \mathcal{C}(x,a) \Rightarrow \mathcal{C}(x,b) \) is an equivalence in \( \mathcal{Cat} \).

Conversely, by essential surjectivity of the equivalence \( f_* : \mathcal{C}(b,a) \Rightarrow \mathcal{C}(b,b) \) there exists some \( g : b \to a \) and isomorphism \( \beta : fg \cong \text{id}_b \). By fully-faithfulness of \( f_* : \mathcal{C}(a,a) \Rightarrow \mathcal{C}(a,b) \) the isomorphism \( \beta^{-1}f : f \cong fgf \) lifts to an isomorphism \( \alpha : \text{id}_a \cong gf \). \( \square \)

Similarly, an adjoint functor in a 2-category induces pointwise-defined adjunctions between the hom-categories, but in this case, a further “exactness” condition is required to convert a representably-defined adjunction into an adjunction in the 2-category.

**B.6.2. PROPOSITION (adjunctions are representably defined).** A 1-cell \( u : a \to b \) in a 2-category \( \mathcal{C} \) admits a left adjoint if and only if:
(i) For all $x \in C$, the induced functor admits a left adjoint

\[ C(x, a) \rightleftharpoons \perp \quad C(x, b) \]

(ii) For all $k : y \to x \in C$, the mate of the identity 2-cell is an isomorphism:

\[ C(x, a) \quad C(\cdot, a) \quad C(x, b) \quad C(\cdot, b) \]

\[ \eta \quad f^* \quad \cong \quad \epsilon \]

**Proof.** The other Yoneda embedding 2-functor $\mathcal{Y} : C \hookrightarrow \mathcal{C}^{\text{op}}$ preserves adjunctions, carrying an adjoint pair $f \dashv u$ in $C$ to an adjunction between the representable 2-functors $\mathcal{C}(\cdot, a)$ and $\mathcal{C}(\cdot, b)$

\[ \mathcal{C}(\cdot, a) \rightleftharpoons \perp \quad \mathcal{C}(\cdot, b) \]

whose left and right adjoints are the 2-natural transformations $f_* \dashv u_*$ and whose unit and counit are modifications. Evaluating at $x \in C$, this defines a family of adjunction as in (i) and strict adjunction morphisms, i.e., so that any $k : y \to x$ induces a strictly commutative square with respect to the left and right adjoints inhabited by a mate pair of identity 2-cells.

The real content is in the converse. Assuming (i), define a candidate left inverse by $f := f_b(id_b)$. By construction $uf := u_* f_b(id_b)$ so we may define a candidate unit to be the component of the unit $\eta_b$ of $f_b \dashv u_*$ at $id_b$:

\[ \eta := \text{id}_b \quad \eta_{id_b} \quad uf \quad \in C(b, b). \]

Note that these definitions do not a priori give any information about the other composite $fu \in C(a, a)$, but condition (ii) defines a natural isomorphism $\alpha : f^a u^* \cong u^* f^b$

\[ C(b, a) \quad \longrightarrow \quad C(a, a) \quad \]

\[ f^b \quad \cong \quad \epsilon^a u^* f^b f^a u^* \eta_b \quad \alpha \]

\[ C(b, b) \quad \longrightarrow \quad C(a, b) \quad \]

whose component at $id_b$ defines an isomorphism

\[ \alpha_{id_b} := f^a(u) \quad f^a(u_* fu) \quad \cong \quad f^a u_* (fu) \quad \epsilon^a(fu) \quad f u \quad \in C(a, a). \]

Using this, we define the counit to be the composite of the inverse of this isomorphism with the component of the counit $\epsilon^a$ of $f^a \dashv u_*$ at $id_l$:

\[ \epsilon := fu \quad \alpha_{id_b}^{-1} \quad f^a(u) \quad \epsilon^a_{id_b} \quad \text{id}_a \quad \in C(a, a). \]
The commutative diagram

\[
\begin{array}{c}
\eta u \\
\eta f(u) \\
u \alpha (u)
\end{array}
\quad \begin{array}{c}
uf \\
f \alpha (ufu) \\
u \alpha (uf)
\end{array}
\quad \begin{array}{c}
uf \\
u \alpha (ufu) \\
u \alpha (ufu)
\end{array}
\]

reveals that \(u \alpha_{id_b} \cdot \eta^a u = \eta u\), so

\[
u e \cdot \eta u = (ue_{id_b}^a \cdot u \alpha_{id_b}^{-1}) \cdot (u \alpha_{id_b} \cdot \eta^a u) = ue_{id_b}^a \cdot u \alpha_{id_b} = id_u,
\]

which verifies one of the two triangle equalities.

It is somewhat delicate to prove that the other triangle equality composite

\[
f \xrightarrow{f \eta} uf \xrightarrow{e f} f \in C(b, a)
\]

is the identity because we don’t have any way to understand the arrow \(f \eta\). Note, however, that this arrow defines an endomorphism of the object \(f^b(id_b) \in C(b, a)\), so if we verify that its transpose under the adjunction \(f^b \dashv u_*\) is the unit component \(\eta_{id_b}^b\), then by uniqueness of adjoint transposition, we must have \(ef \cdot f \eta = id_f\) as desired. This can be verified by direct calculation: the adjoint transpose is computed by applying the functor \(u_*\) and then precomposing with \(\eta_{id_b}^b = \eta\), which yields the left-bottom composite below.

\[
\begin{array}{c}
1 \\
\eta \\
u f
\end{array}
\quad \begin{array}{c}
u f \\
u \alpha (ufu) \\
u \alpha (ufu)
\end{array}
\quad \begin{array}{c}
u f \\
u \alpha (ufu) \\
u \alpha (ufu)
\end{array}
\]

An easy diagram chase making use of the previously-verified triangle equality completes the proof. □

Condition (ii) of Proposition B.6.2 is referred to as a “Beck-Chevalley” or exactness condition. Another exactness condition appears in a representable characterization of absolute lifting diagrams.

B.6.3. Definition. A trio of functors \((u, v, w)\) between a pair of absolute left lifting diagrams \((\ell, \lambda)\) and \((\ell', \lambda')\) as below defines a left exact transformation if and only if the 2-cell \(\tau\) induced by the universal property of the absolute left lifting is invertible:

\[
\begin{array}{c}
\epsilon \\
f \\
v
\end{array}
\quad \begin{array}{c}
\eta \lambda \\
\eta f \\
\eta f
\end{array}
\quad \begin{array}{c}
\epsilon \\
f \alpha (ufu) \\
f \alpha (ufu)
\end{array}
\quad \begin{array}{c}
\epsilon \\
f \alpha (ufu) \\
f \alpha (ufu)
\end{array}
\]

This left exactness condition holds if and only if, in the diagram on the left of (B.6.4), the whiskered 2-cell \(u \lambda \) displays \(v \ell\) as the absolute left lifting of \(g'w\) through \(f'\), which is to say that the left exact transformations are those that preserve absolute left lifting diagrams.
B.6.5. **Lemma.** The mate of a commutative square between right adjoints as below
\[
\begin{array}{ccc}
  a & \xrightarrow{h} & a' \\
  f' & \downarrow{u} & f'' \\
  b & \xleftarrow{k} & b' \\
  b'' & \xrightarrow{k' \circ f} & b''
\end{array}
\]
is invertible if and only if \((k, h, k)\) defines a left exact transformation between the absolute left lifting diagrams \((f, \eta)\) and \((f', \eta')\) of \(\text{id}_b\) through \(u\) and \(\text{id}_{b'}\) through \(u'\).

**Proof.** The unique 2-cell \(\tau\) satisfying the pasting diagram below is the mate of \(\text{id} : ku \Rightarrow u'h\).

\[
\begin{array}{ccc}
  f & \downarrow{\eta} & a \\
  b & \xrightarrow{k} & b' \\
  \exists! \tau & \downarrow{u} & a' \\
  b' & \xrightarrow{u'} & b'
\end{array}
\]

B.6.6. **Proposition.** Consider a 2-cell in a 2-category \(\mathcal{C}\)

\[
\begin{array}{ccc}
  \ell & \downarrow{\lambda} & b \\
  c & \xrightarrow{f} & a
\end{array}
\]

(i) If \((\ell, \lambda)\) defines an absolute left lifting diagram in \(\mathcal{C}\), then

(a) For all \(x \in \mathcal{C}\),

\[
\begin{array}{ccc}
  C(x, b) & \xrightarrow{\ell_*} & C(x, c) \\
  \downarrow{f_*} & \xrightarrow{g_*} & \downarrow{g_*} \\
  C(x, a) & \xrightarrow{f_*} & C(x, a)
\end{array}
\]

defines an absolute left lifting diagram in \(\text{Cat}\).

(b) For all \(k : w \rightarrow x \in \mathcal{C}\), the induced transformation

\[
\begin{array}{ccc}
  C(x, b) & \xrightarrow{k^*} & C(w, b) \\
  \downarrow{f_*} & \xrightarrow{g_*} & \downarrow{g_*} \\
  C(w, c) & \xrightarrow{k^*} & C(w, a)
\end{array}
\]

is left exact.

(ii) Conversely if ((i)a) holds for each \(x \in \mathcal{C}\), then \((\ell, \lambda)\) defines an absolute left lifting diagram in \(\mathcal{C}\).

(iii) Moreover, if \(g : c \rightarrow a\) and \(f : b \rightarrow a\) are so that for all \(x \in \mathcal{C}\), the functor \(g_* : C(x, c) \rightarrow C(x, a)\) admits an absolute left lifting through \(f_* : C(x, b) \rightarrow C(x, a)\) for which condition ((i)b) holds, then \(g\) admits an absolute left lifting through \(f\) in \(\mathcal{C}\).
Proof. We leave the proof of the first statement, which is the most straightforward, to the reader with the hint that to verify the universal property of an absolute lifting diagram in \( \text{Cat} \), it suffices to consider cones over the cospan \((g_*, f_*)\) whose summit is the terminal category \(1\).

For the second assertion, consider a cone
\[
\begin{array}{ccc}
{x} & \xrightarrow{y} & {b} \\
\downarrow{z} & & \downarrow{f} \\
{c} & \xrightarrow{g} & {a}
\end{array}
\]
over the cospan \((g, f)\) in \( C \). This data defines a diagram of categories as below-left, which factors uniquely as below-right:
\[
\begin{array}{ccc}
1 & \xrightarrow{y} & {C(x, b)} \\
\downarrow{z} & & \downarrow{f_*} \\
{C(x, c)} & \xrightarrow{g_*} & {C(x, a)}
\end{array}
= \begin{array}{ccc}
1 & \xrightarrow{y} & {C(x, b)} \\
\downarrow{z} & & \downarrow{f_*} \\
{C(x, c)} & \xrightarrow{g_*} & {C(x, a)}
\end{array}
\]
defining the desired unique factorization
\[
\begin{array}{ccc}
{x} & \xrightarrow{y} & {b} \\
\downarrow{z} & & \downarrow{f} \\
{c} & \xrightarrow{g} & {a}
\end{array}
= \begin{array}{ccc}
{x} & \xrightarrow{y} & {b} \\
\downarrow{z} & & \downarrow{f} \\
{c} & \xrightarrow{g} & {a}
\end{array}
\]

For the final statement, we define the pair \((\ell, \lambda)\) by evaluating the functor and natural transformation of the postulated absolute left lifting \((\ell^c, \lambda^c)\) in the case \( x = c \) at \( \text{id}_c \in C(c, c) \). To verify that \( \lambda: f \ell \Rightarrow g \) defines an absolute left lifting of \( g \) through \( f \), consider a 1-cell \( z: x \to c \). The hypothesis of left-exactness tells us that the composite transformation
\[
\begin{array}{ccc}
1 & \xrightarrow{id_c} & {C(c, c)} \\
\downarrow{\ell^c} & & \downarrow{f_*} \\
{C(x, c)} & \xrightarrow{g_*} & {C(x, a)}
\end{array}
\]
is absolute left lifting. By the proof of the second statement above, this tells us that \((\ell c, \lambda c)\) is an absolute left lifting of \(gc\) through \( f \), which proves that \((\ell, \lambda)\) is an absolute left lifting as required. \(\square\)

B.6.7. Remark. The results of Proposition B.6.2 and Proposition B.6.6 can be viewed as applications of the bicategorical Yoneda lemma, which defines a 2-fully faithful embedding of a bicategory \( C \) into the 2-category \([C^{\text{op}}, \text{Cat}]\) of pseudofunctors, pseudonatural transformations, and modifications; see Definitions 10.4.1, 10.4.2, and B.2.3. If a 1-cell \( u: a \to b \) in \( C \) satisfies condition (i) of Proposition B.6.2, then by Theorem B.3.6, the left adjoints \( f^x: C(x, b) \to C(x, a) \) define the components of a lax natural transformation. Condition (ii) demands that this lax natural transformation is a pseudo natural transformation. Now 2-fully faithfulness allows us to lift this to an arrow \( f: b \to a \) in \( C \), which is left adjoint to \( u \).
In the case of Proposition B.6.1, where \( u : a \to b \) induces equivalences \( C(x, a) \cong C(x, b) \), the inverses can be chosen to define adjoint equivalences, which automatically assemble into a pseudonatural transformation; see Lemma 10.4.15. This is why no additional hypothesis was required.

**Exercises.**

B.6.i. **Exercise.** Confirm the assertion made in the proof of Lemma B.6.5.

APPENDIX C

Abstract Homotopy Theory

The underlying 1-category of an \(\infty\)-cosmos, together with its classes of isofibrations, equivalences, and trivial fibrations, defines a category of fibrant objects, a categorical setting for abstract homotopy theory first studied by Brown \([23]\). In §C.1, we develop some of the general theory of categories of fibrant objects with the aim of presenting some classical proofs that were omitted in the main text.

The remainder of this chapter develops material that is applied in later appendices. In Appendix E, we discover that examples of \(\infty\)-cosmoi can be found “in the wild” as model categories that are enriched as such over Joyal’s model structure on the category of simplicial sets. To explain the notions that feature in the statements and proofs of these results, model categories, enriched model categories, and the functors between them are introduced in §C.3.

The notion of a model category is due to Quillen \([90]\). In the introduction to “Chapter I. Axiomatic Homotopy Theory” where the definition first appears, Quillen highlights the factorization and lifting axioms as being the most important. These are most clearly encapsulated in the categorical notion of a weak factorization system discussed in §C.2, the axioms for which were enumerated later.

Finally, some of the technical combinatorial proofs of Appendix D involve inductive arguments involving the Reedy category \(\Delta\). Thus, we conclude in §C.4 and §C.5 with a brief introduction to Reedy category theory and the Reedy model structure following the presentation of \([102]\).

C.1. Abstract Homotopy Theory in a Category of Fibrant Objects

In this section, we work in an (unenriched) category of fibrant objects, a notion first introduced by Brown \([23]\). Examples include the underlying category of an \(\infty\)-cosmos or the full subcategory of fibrant objects in a Quillen model category (hence the name).

C.1.1. Definition (category of fibrant objects). A category of fibrant objects consists of a category \(\mathcal{M}\) together with two subcategories of morphisms \(\mathcal{W}\) and \(\mathcal{F}\) satisfying the following axioms:

(i) \(\mathcal{M}\) has products and in particular a terminal object \(1\). Moreover, the classes \(\mathcal{F}\) and \(\mathcal{F} \cap \mathcal{W}\) are each closed under products.

(ii) \(\mathcal{W}\) has the 2-of-3 property: for any composable pair of morphisms, if any two of \(f\), \(g\), and \(gf\) is in \(\mathcal{W}\) then so is the third.

(iii) Pullbacks of maps in \(\mathcal{F}\) exist and lie in \(\mathcal{F}\), and the class \(\mathcal{F} \cap \mathcal{W}\) is also stable under pullback.

(iv) Limits of countable towers\(^1\) of maps in \(\mathcal{F}\) exist and also lie in \(\mathcal{F}\), and the class \(\mathcal{F} \cap \mathcal{W}\) is also closed under forming limits of towers.

\(^1\)A (countable) tower is a diagram of shape \(\omega^\alpha\). More general towers, indexed by other limit ordinals, will be considered in Lemma C.2.3 and beyond.
(v) For every object $B$, there exists a path object $PB$ together with a factorization of the diagonal into a map in $W$ followed by a map in $F$:

$$
B \xrightarrow{PB} B \times B \xrightarrow{\Delta} B
$$

(vi) All objects are fibrant: for every $B \in M$, the map $B \to 1$ lies in $F$.

C.1.2. Remark. The original definition only asked for the existence finite products in axiom (i) and omitted axiom (iv). The closure of the classes $F$ and $F \cap W$ under finite products follows, by induction, from the closure under pullback assumed in axiom (iii); see Corollary C.1.14. Here, we ask for these infinite limits to parallel the limit axiom 1.2.1(i) in our definition of an $\infty$-cosmos. In practice, the classes $F$ and $F \cap W$ are frequently characterized by a right lifting property, in which case the closure axioms (i), (iii), and (iv) are automatic; see Lemma C.2.3.

In general, it is customary to refer to the maps in $W$ as “weak equivalences”, the maps in $F$ as “fibrations,” and the maps in $F \cap W$ as “trivial fibrations” — unless the specific context dictates alternate names — and depict these classes by the decorated arrows, $\Rightarrow$, $\rightarrow$, and $\Rightarrow\Rightarrow$, respectively. Our primary interest in categories of fibrant objects is on account of the following two examples.

C.1.3. Example. The underlying category of an $\infty$-cosmos defines a category of fibrant objects with $W$ the class of equivalences and $F$ the class of isofibrations. Most of the axioms of Definition C.1.1 are subsumed by the limit and isofibration axioms of Definition 1.2.1. The remaining pieces are established in Lemma 1.2.14, Lemma 1.2.16, and Lemma 1.2.20.

C.1.4. Example. In the terminology of Definition C.3.2, the full subcategory of fibrant objects in a model category defines a category of fibrant objects with $W$ the class of weak equivalences and $F$ the class of fibrations between fibrant objects. The proof is left as Exercise C.3.i.

C.1.5. Remark. Both of the examples just discussed have the additional property of being right proper, satisfying an additional axiom:

(vii) Pullbacks of maps in $W$ along maps in $F$ define maps in $W$:

$$
\begin{array}{ccc}
F & \xrightarrow{g} & E \\
q \downarrow & & \downarrow p \\
A & \xrightarrow{f} & B
\end{array}
$$

For $\infty$-cosmoi this is proven in Proposition 3.3.2 and for model categories, this was first observed by Reedy in [94, Theorem B] (see also [82, 15.4.2]).

The factorization axiom in a category of fibrant objects can be generalized to construct factorizations of any map; cf. Lemma 1.2.16

C.1.6. Lemma (Brown factorization lemma). Any map $f : A \to B$ in a category of fibrant objects may be factored as a weak equivalence followed by an fibration, where the weak equivalence is constructed as a section.
of a trivial fibration.

Moreover, \( f \) is a weak equivalence if and only if the fibration \( p \) is a trivial fibration.

**Proof.** The displayed factorization is constructed by the pullback of the path object fibration \( PB \to B \times B \) of (v):

By the 2-of-3 property for the weak equivalences, both projections \( PB \to B \) are trivial fibrations. Since the map \( q \) is a pullback of one of these projections along \( f : A \to B \), it follows from axiom (iii) that \( q \) is a trivial fibration. Its section \( s \), constructed by applying the universal property of the pullback to the displayed cone with summit \( A \), is thus an equivalence. Finally, if either \( f \) or \( p \) are weak equivalences, the other must be as well by the 2-of-3 property. \( \square \)

In analogy with Proposition 1.2.22:

C.1.7. **Corollary.** If \( \mathcal{M} \) is a category of fibrant objects and \( B \in \mathcal{M} \), then the category \( \mathcal{M}_B \) of fibrations in \( \mathcal{M} \) with codomain \( B \) and maps over \( B \) becomes a category of fibrant objects with weak equivalences and fibrations created by the forgetful functor \( \mathcal{M}_B \to \mathcal{M} \).

**Proof.** The construction of limits in the slice category \( \mathcal{M}_B \) is described in the proof of Proposition 1.2.22; note in particular, that \( \text{id}_B \) is the terminal object, so all objects in \( \mathcal{M}_B \), being fibrations in \( \mathcal{M} \), are fibrant. Path objects for a fibration \( f : A \to B \) are constructed by applying Lemma C.1.6 to the “diagonal” map \( (f, f) : A \to A \times_B A \). From \( A \) to the pullback of \( f \) along itself. \( \square \)

The dual of a result of Blumberg and Mandell [19, 6.4] demonstrates that the equivalences in any \( \infty \)-cosmos satisfy the 2-of-6 property. The proof reveals that this holds in any category of fibrant objects in which the class \( \mathcal{W} \) is closed under retracts.

C.1.8. **Proposition.** Let \( \mathcal{M} \) be a category with classes of maps \( \mathcal{W} \) and \( \mathcal{F} \) so that:

- \( \mathcal{W} \) satisfies the 2-of-3 property, and is closed under retracts.
- The pullback of a map in \( \mathcal{F} \cap \mathcal{W} \) is in \( \mathcal{F} \cap \mathcal{W} \) and these pullbacks always exist.
- Every map in \( \mathcal{W} \) factors as a section of a map in \( \mathcal{F} \cap \mathcal{W} \) followed by a map in \( \mathcal{F} \cap \mathcal{W} \).
Then the class \( \mathcal{W} \) satisfies the 2-of-6 property: for any composable triple of morphisms

\[
\begin{array}{cccc}
A & 
& B & 

\downarrow f & 

\downarrow hgf & 

\downarrow hg & 

\downarrow g & 

\downarrow h & 

\downarrow gf & 

\downarrow g & 

\downarrow h & 

\downarrow \sim & 

C
\end{array}
\]

if \( gf \) and \( hg \) are in a class \( \mathcal{W} \) then \( f, g, h, \) and \( hgf \) are too.

**Proof.** Form the factorization of the map \( hg \) as displayed below

\[
\begin{array}{cccc}
B & 
& D' & 

\downarrow j & 

\downarrow \sim & 

\downarrow p & 

\downarrow r & 

\downarrow \sim & 

D
\end{array}
\]

and form the pullback of \( p \) along \( h \) and the induced map \( t \):

\[
\begin{array}{cccc}
A & 
& B & 

\downarrow f & 

\downarrow i 

\downarrow t f & 

\downarrow f & 

\downarrow \sim & 

C' & 

\downarrow q & 

\downarrow \sim & 

D' & 

\downarrow r & 

\downarrow \sim & 

D
\end{array}
\]

By pullback stability of the trivial fibrations, the map \( q \) is in \( \mathcal{W} \), so by the 2-of-3 property and the assumption that \( gf \) is in \( \mathcal{W} \), the composite \( t f : A \to C' \) must be in \( \mathcal{W} \). The map \( f \) is a retract of this composite

\[
\begin{array}{cccc}
A & 
& A & 

\downarrow f & 

\downarrow i 

\downarrow t f & 

\downarrow f & 

\downarrow \sim & 

C' & 

\downarrow r u & 

\downarrow \sim & 

B
\end{array}
\]

so by retract closure of the class \( \mathcal{W} \), \( f \) is in \( \mathcal{W} \). Now it follows from the 2-of-3 property that \( g, h, \) and \( hgf \) lie in \( \mathcal{W} \) as well. \( \square \)

C.1.9. **Corollary.** The equivalences in an \( \infty \)-cosmos satisfy the 2-of-6 property.

**Proof.** It remains only to argue that the premises of Proposition C.1.8 hold for the classes of equivalences, isofibrations, and trivial fibrations in any \( \infty \)-cosmos.

Lemma 1.2.20 proves that the equivalences in an \( \infty \)-cosmos are also closed under retracts and have the 2-of-3 property. Lemma 1.2.14 proves that the class of trivial fibrations is stable under pullbacks, which exist in any \( \infty \)-cosmos. Lemma 1.2.16 constructed the desired factorization, which by the 2-of-3 property factors an equivalence as a section of a trivial fibration followed by a trivial fibration. Now Proposition C.1.8 applies to prove that the equivalences in any \( \infty \)-cosmos satisfy the stronger 2-of-6 property. \( \square \)
The following consequence of Lemma C.1.6, traditionally referred to as “Ken Brown’s lemma,” is the key to proving the equivalence invariance of many constructions in a category of fibrant objects.

C.1.10. **Lemma (Ken Brown's lemma).** Consider a functor \( F : \mathcal{M} \to \mathcal{N} \) whose domain is a category of fibrant objects and whose codomain is a category with a subcategory of “weak equivalences” satisfying the 2-of-3 property. If \( F \) carries trivial fibrations to weak equivalences, then \( F \) carries weak equivalences in \( \mathcal{M} \) to weak equivalences in \( \mathcal{N} \).

**Proof.** By the 2-of-3 property of the weak equivalences in \( \mathcal{M} \), any weak equivalence in a category of fibrant objects may be factored as a section of a trivial fibration followed by a trivial fibration.

\[
\begin{array}{ccc}
P f & \\ \downarrow q & \\ A & \sim & B \\
\end{array} \quad \begin{array}{ccc}
p & \\ \downarrow f & \\ \end{array}
\]

By hypothesis, the images of the maps \( q \) and \( p \) under \( F \) are weak equivalences. By the 2-of-3 property of the weak equivalences in \( \mathcal{N} \), it follows that the image of \( s \) and thus also the image of \( f \) are weak equivalences. \( \square \)

The rest of this section is devoted to applications of Lemma C.1.10 to establish the weak equivalence invariance of limits in a category of fibrant objects. To warm up, as a very easy consequence:

C.1.11. **Lemma.** In a category of fibrant objects, a weak equivalence between fibrations pulls back to a weak equivalence between fibrations:

\[
\begin{array}{ccc}
P & \longrightarrow & E \\
\downarrow r & \nearrow u & \downarrow p \\
A & \leftarrow Q & \longrightarrow F \\
\downarrow s & \searrow d & \downarrow q \\
\end{array}
\]

**Proof.** By Corollary C.1.7, slices of a category \( \mathcal{M} \) of fibrant objects define categories of fibrant objects and pullback along \( f \) defines a functor \( f^* : \mathcal{M}_B \to \mathcal{M}_{fA} \). Note that the map \( u \) in the displayed diagram is the pullback of the map \( e \), so it follows directly from axiom (iii) of Definition C.1.1 that pullback preserves trivial fibrations. Now Lemma C.1.10 implies that it also preserves equivalences. \( \square \)

Other results in a similar vein require somewhat more delicate arguments. The proofs appearing below are originally due to Reedy in an unpublished manuscript [94] that implicitly gave birth to the notion of a “Reedy category” that we introduce in §C.4.

C.1.12. **Proposition.** Consider a diagram in a category of fibrant objects:

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A & \xleftarrow{f} & B \\
\downarrow r & & \downarrow p & & \downarrow q \\
\tilde{C} & \xrightarrow{\tilde{g}} & \tilde{A} & \xleftarrow{\tilde{f}} & \tilde{B} \\
\end{array}
\]

If the map \( r \) and the map \( z : B \to A \times \tilde{A} \) are both...
(i) fibrations, or  
(ii) trivial fibrations  
then the induced map from the pullback of \( f \) along \( g \) to the pullback of \( \bar{f} \) along \( \bar{g} \) again a fibration or trivial fibration, respectively.

**Proof.** By repeatedly applying the pullback composition and cancelation lemma, one discovers that the induced map \( t \) factors as a pullback of \( z \) followed by a pullback of \( r \) as displayed below

\[
\begin{array}{c}
C \times B \xrightarrow{t} B \\
\downarrow^A \ \\
C \xrightarrow{r} A \xleftarrow{p} \bar{B} \xrightarrow{q} \bar{A} \\
\end{array}
\]

and is thus an fibration or trivial fibration if both of these maps are. \( \square \)

Similarly, we have the following result whose dual form is sometimes called the “gluing lemma.”

**C.1.13. Proposition.** In a category of fibrant objects, the induced map between the pullbacks of the horizontal rows of a diagram

\[
\begin{array}{c}
C \xrightarrow{g} A \xleftarrow{f} B \\
\downarrow^r \ \\
\bar{C} \xrightarrow{\bar{g}} \bar{A} \xleftarrow{\bar{f}} \bar{B} \\
\end{array}
\]

is again a weak equivalence.

The proof of Proposition 3.3.3 applies equally in any right proper category of fibrant objects, but as we shall discover, the hypothesis of right properness is not actually necessary.

**Proof.** By Exercise C.1.i, for any category of fibrant objects \( \mathcal{M} \) there is a category of fibrant objects \( \mathcal{M}^\circ \) whose

- objects are cospans \( C \xrightarrow{g} A \xleftarrow{f} B \) whose right leg is a fibration in \( \mathcal{M} \),
- weak equivalences are pointwise weak equivalences, and
- fibrations are diagrams

\[
\begin{array}{c}
C \xrightarrow{g} A \xleftarrow{f} B \\
\downarrow^r \ \\
\bar{C} \xrightarrow{\bar{g}} \bar{A} \xleftarrow{\bar{f}} \bar{B} \\
\end{array}
\]

in which the maps \( r, p, \) and \( q \) are fibrations, as is the induced map \( z \colon B \to A \times \bar{A} \bar{B} \).
with the requisite limits inherited pointwise from $\mathcal{M}$. By Proposition C.1.12, the colimit functor $\text{colim} : \mathcal{M}^\omega \to \mathcal{M}$ carries trivial fibrations to trivial fibrations, so by Lemma C.1.10, it also preserves weak equivalences.

C.1.14. COROLLARY. In a category of fibrant objects, finite products of fibrations, trivial fibrations, or weak equivalences are again finite products, trivial fibrations, or weak equivalences.

PROOF. The product of a finite family of maps $\{f_i : A_i \to \tilde{A}_i\}_{i=1,\ldots,n}$ can be built inductively by forming the product as a pullback over the terminal object $1$

$$\begin{array}{cccc}
\Pi_{i=1}^{n-1} A_i & \longrightarrow & 1 & \leftarrow & A_n \\
\Pi_i f_i & \downarrow & & & \downarrow f_n \\
\Pi_{i=1}^{n-1} \tilde{A}_i & \longrightarrow & 1 & \leftarrow & \tilde{A}_n
\end{array}$$

When each map $f_i$ is a fibration or trivial fibration, by induction starting from the case of binary products and Proposition C.1.12, the same is true of the product of these maps. When each map $f_i$ is a weak equivalence, the same conclusion follows from Proposition C.1.13.

Similarly, limits of towers of fibrations are invariant under pointwise weak equivalence:

C.1.15. PROPOSITION. Consider a natural transformation between countable towers of fibrations in a category of fibrant objects

$$\begin{array}{cccc}
X_\omega := \lim_n X_n & \longrightarrow & \cdots & \longrightarrow & X_2 & \longrightarrow & X_1 & \longrightarrow & X_0 \\
\alpha_n & \downarrow & \cdots & & \downarrow & \alpha_2 & \downarrow & \alpha_1 & \downarrow & \alpha_0 \\
Y_\omega := \lim_n Y_n & \longrightarrow & \cdots & \longrightarrow & Y_2 & \longrightarrow & Y_1 & \longrightarrow & Y_0
\end{array}$$

(i) If for each $n \geq 0$, the map $\langle \alpha_n, f_n \rangle : X_n \to Y_n \times_{Y_{n-1}} X_{n-1}$ is a fibration or trivial fibration,² then the induced map $\alpha_\omega$ between the limits is as well.

(ii) If for each $n \geq 0$, the map $\alpha_n$ is a weak equivalence, then the induced map $\alpha_\omega$ between the limits is as well.

PROOF. When the hypotheses of (i) hold in a category of fibrant objects $\mathcal{M}$, the induced map $\alpha_\omega : X_\omega \to Y_\omega$ between the limits of the towers of fibrations is itself the limit composite of a tower of fibrations or trivial fibrations, respectively

$$\begin{array}{cccc}
P_n & \longrightarrow & P_{n-1} & \longrightarrow & \cdots & \longrightarrow & P_1 & \longrightarrow & P_0 & \longrightarrow & Y_\omega \\
\alpha_\omega & & & & & & & & & & \longrightarrow
\end{array}$$

where each layer is a pullback of the map

$$\begin{array}{cccc}
P_n & \longrightarrow & P_{n-1} \\
\downarrow & & \downarrow \\
X_n & \longrightarrow & Y_n \times_{Y_{n-1}} X_{n-1}
\end{array}$$

²To make sense of this when $n = 0$ declare $X_{n-1}$ and $Y_{n-1}$ to be terminal; the map under consideration is $\alpha_0$. 485
assumed to be either a fibration or a trivial fibration. Starting from the bottom $P_0$ is defined to be the pullback

\[
P_0 \longrightarrow Y_\omega \\
\downarrow \downarrow \downarrow \\
X_0 \longrightarrow a_0 \longrightarrow Y_0
\]

of $\alpha_0$ along the leg. By construction, $P_0$ admits a canonical map to the pullback $Y_1 \times_{Y_0} X_0$ and $P_1$ is defined to be the pullback

\[
P_1 \longrightarrow P_0 \\
\downarrow \downarrow \downarrow \\
X_1 \longrightarrow (\alpha_1, f_1) \longrightarrow Y_1 \times_{Y_0} X_0
\]

Continuing inductively, the limit of the tower of fibrations $P_n \Rightarrow P_{n-1}$ can be seen to coincide with the limit of the $\omega^{op} \times \mathbb{Z}$ shaped diagram formed by the maps $f_n$, $g_n$, and $\alpha_n$. Since the inclusion $\omega^{op} \hookrightarrow \omega^{op} \times \mathbb{Z}$ of the top row of this diagram is initial, this limit recovers $X_\omega$ and the composite of the tower of fibrations recovers the map $\alpha_\omega$. Thus, by axioms (iii) and (iv) of Definition C.1.1, the induced map $\alpha_\omega$ is again a fibration or trivial fibration, respectively.

The second statement now follows by applying Lemma C.1.10 to the limit functor $\lim : \mathcal{M}^{\omega^{op}} \rightarrow \mathcal{M}$ whose domain is the category of towers of fibrations; see Exercise C.1.ii. 

Again in this proof we have made use of the fact that the category of diagrams valued in a category of fibrant objects may itself be equipped with the structure of a category of fibrant objects, at least for certain diagram shapes. We now establish this result more systematically for a particularly useful family of diagrams, namely those indexed by inverse categories.

C.1.16. Definition. A category $\mathcal{I}$ is a inverse category if there exists a functor $\mathcal{I} \xrightarrow{\text{deg}} \omega^{op}$ that reflects identities.

³The degree functor assigns a natural number degree to each object of $\mathcal{I}$ in such a way that all non-identity morphisms “lower degree,” in the sense that the degree of their domain object is strictly greater than the degree of their codomain object. The utility of this axiomatization is it allows us to define the data of an $\mathcal{I}$-indexed diagram or natural transformation by inductively specifying diagrams indexed by the full subcategories

\[
\mathcal{I}_{\leq 0} \hookrightarrow \cdots \hookrightarrow \mathcal{I}_{\leq n-1} \hookrightarrow \mathcal{I}_{\leq n} \hookrightarrow \cdots \hookrightarrow \text{colim}_{n \in \omega} \mathcal{I}_{\leq n} \cong \mathcal{I}
\]

of objects with bounded degree. To extend $X \in \mathcal{M}^{\mathcal{I}_{\leq n-1}}$ to $\mathcal{M}^{\mathcal{I}_{\leq n}}$ requires the specification, for each object $i$ with degree $n$ of an object $X^i \in \mathcal{M}$ together with a map $X^i \rightarrow \partial^i X$ from $X^i$ to the limit

\[
\partial^i X := \lim \left( \mathcal{I}_{\leq n-1} \xrightarrow{i} \mathcal{I}_{\leq n-1} \xrightarrow{X} \mathcal{M} \right) \quad \text{(C.1.17)}
\]

indexed by the non-identity maps $i \rightarrow j$ in $\mathcal{I}$.

³The mathematics does not change in any substantial way if $\omega$ is replaced by the category of ordinals. The reason we restrict to finite degrees is because we have only asked for limits of $\omega^{op}$-indexed towers in Definition C.1.1. See Proposition C.1.21(ii).
C.1.18. Observation (boundary data as a weighted limit). As the notation suggests, the object \( \partial^i X \) should be thought of as the object of “boundary data” associated to \( X^i \). This intuition can be made precise through the formalism of weighted limits, illustrating their utility even in unenriched contexts.

Recall from Definition A.6.1(i) that the limit of a diagram \( X \in \mathcal{M}^\mathcal{I} \) weighted by the representable functor \( \mathcal{I}(i, -) \in \text{Set}^\mathcal{I} \) at an object \( i \in \mathcal{I} \) is the object \( X_i \). Define the boundary \( \partial \mathcal{I}(i, -) \) of the representable functor to be the functor defined by

\[
\partial \mathcal{I}(i, j) := \begin{cases} 
\mathcal{I}(i, j) & \text{deg}(j) < \text{deg}(i) \\
\emptyset & \text{deg}(j) \geq \text{deg}(i)
\end{cases}
\]

By comparing (C.1.17) with the formula of Remark A.6.11 one sees that \( \lim_{\partial \mathcal{I}(i, -)} X \cong \partial^i X \).

Recall from Definition A.6.1, that weighted limits are contravariantly functorial in the weight. Thus, the natural inclusion \( \partial \mathcal{I}(i, -) \hookrightarrow \mathcal{I}(i, -) \) induces a canonical map

\[
X_i \cong \lim_{\mathcal{I}(i, -)} X \xrightarrow{m_i} \lim_{\partial \mathcal{I}(i, -)} X \cong \partial^i X
\]

between the weighted limits.

Anticipating the terminology of Definition C.4.16 we refer to \( \partial^i X \) as the \( i \)th matching object of the diagram \( X \) and refer to \( m_i : X_i \to \partial^i X \) as the \( i \)th matching map.

For reasons that will momentarily become clear we define:

C.1.19. Definition. Let \( \mathcal{M} \) be a category of fibrant objects and let \( \mathcal{I} \) be an inverse category.

- If \( X \in \mathcal{M}^\mathcal{I} \) is a diagram with the property that for each \( i \in \mathcal{I} \), the matching map \( m_i : X_i \to \partial^i X \) is a fibration, then call \( X \) a fibrant diagram.

- If \( \alpha : X \to Y \in \mathcal{M}^\mathcal{I} \) is a natural transformation between fibrant diagrams so that for each \( i \in \mathcal{I} \) the map \( \hat{m}_i \) defined by

\[
\begin{array}{ccc}
X_i & \xrightarrow{\alpha_i} & Y_i \\
\downarrow{m_i} & \swarrow{\hat{m}_i} & \downarrow{m_i} \\
\partial^i X & \xrightarrow{\partial^i \alpha} & \partial^i Y
\end{array}
\]

(C.1.20)

is a fibration, then call \( \alpha : X \to Y \) a fibrant natural transformation.

For example, a fibrant diagram of shape \( \omega \) is a tower of fibrations, as in Proposition C.1.15. The maps referenced in the first statement of that result are exactly the relative matching maps associated to a natural transformation \( \alpha \) between fibrant diagrams, so the first hypothesis asserts exactly that \( \alpha \) is a fibrant natural transformation. The following generalization of Proposition C.1.15 is an unenriched version of Proposition 6.3.1.

(i) A category of fibrant objects \( \mathcal{M} \) admits limits of any fibrant diagram \( X \in \mathcal{M}^\mathcal{I} \) indexed by an inverse category \( \mathcal{I} \), with \( \lim \mathcal{I} \mathcal{F} \in \mathcal{M} \) constructed as the limit of a tower

\[
\lim_{\mathcal{I}} X := \lim_{\omega^{\text{op}}} \left( \cdots \longrightarrow \lim_{\mathcal{I}_{\geq n}} X \longrightarrow \lim_{\mathcal{I}_{\geq n-1}} X \longrightarrow \cdots \longrightarrow \lim_{\mathcal{I}_{\leq 0}} X \right)
\]
each layer of which is a pullback

\[
\lim_{I_{\leq n}} X \longrightarrow \lim_{I_{\leq n-1}} X \\
\downarrow \quad \quad \quad \downarrow \\
\prod_{\deg(i)=n} X^i \longrightarrow \prod_{\deg(i)=n} \partial^i X
\]

In particular, each leg of the limit cone \( \lim_I X \to X^i \) is a fibration as is each map in the image of the fibrant diagram \( X \).

(ii) For any fibrant natural transformation \( \alpha : X \to Y \in \mathcal{M}^I \) between fibrant diagrams, the induced map \( \lim_I X \to \lim_I Y \) is the limit composite of a tower whose \( n \)-th layer is the map \( p_n \) constructed as a pullback in the diagram below:

\[
\begin{align*}
\lim_{I_{\leq n}} X^i & \longrightarrow \prod_{\deg(i)=n} X^i \\
\downarrow \quad \quad \downarrow \quad \quad \downarrow \\
\lim_{I_{\leq n-1}} X^i & \longrightarrow \prod_{\deg(i)=n} \partial^i X \\
\downarrow \quad \quad \downarrow \quad \quad \downarrow \\
\lim_{I_{\leq n}} Y^i & \longrightarrow \prod_{\deg(i)=n} Y^i \\
\downarrow \quad \quad \downarrow \quad \quad \downarrow \\
\lim_{I_{\leq n-1}} Y^i & \longrightarrow \prod_{\deg(i)=n} \partial^i Y
\end{align*}
\] (C.1.22)

Moreover, each component map \( \alpha^i : X^i \to Y^i \) is a fibration.

**Proof.** Note that the slice category \( i/I_{n-1} \) is again an inverse category with degree functor

\[
i/I_{n-1} \quad \xrightarrow{\text{cod}} \quad I_{n-1} \quad \xrightarrow{\deg} \quad \omega^{op}
\]

in which every object has degree at most \( n-1 \). In the case where \( i \) has degree 1, this category is discrete, so by induction we may assume that the limit \( \partial^i X \) defined by (C.1.17) exists. Now the result of (i) follows by direct inspection of the universal property of this construction, as in the proof of Proposition C.1.15. The final assertion follows from this construction and is left to Exercise C.1.iii.

By (i), it follows that the induced map between the inverse limits is defined as as the limit of an \( \omega^{op} \)-indexed diagram in the arrow category \( \mathcal{M}^2 \):

\[
\lim_I X := \lim_{\eta \in \omega^{op}} \lim_{I_{\eta} X} \longrightarrow \cdots \longrightarrow \lim_{I_{\leq 2} X} \longrightarrow \lim_{I_{\leq 1} X} \longrightarrow \lim_{I_{\leq 0} X} \\
\downarrow \quad \quad \downarrow \quad \quad \downarrow \\
\lim_I Y := \lim_{\eta \in \omega^{op}} \lim_{I_{\eta} Y} \longrightarrow \cdots \longrightarrow \lim_{I_{\leq 2} Y} \longrightarrow \lim_{I_{\leq 1} Y} \longrightarrow \lim_{I_{\leq 0} Y}
\]

Under the hypothesis of (ii), it follows by the proof of Proposition C.1.15(i), the map \( \lim_I \alpha \) then factors as the limit composite of a tower whose bottom layer is the pullback of the map \( p_0 \) along the lower-horizontal composite above, whose next layer is the pullback of the map \( p_1 \) appearing in the right-most square, whose next layer is the pullback of the map \( p_2 \) appearing in the second right-most
square, and so on, where in each square \( p_n \) is the map from the upper left-hand corner to the pullback of the lower-right cospan. The map \( p_0 \) is a product of the relative matching maps indexed by objects of degree zero, and is thus a fibration. By applying pullback composition and cancelation in the cube (C.1.22), it follows from (i) that the top and bottom faces are pullbacks that the map \( p_n \) from the initial vertex to the pullback in the left face is a pullback of the corresponding map from \( \prod_{\deg(i)=n} X^i \) to the pullback in the right face. This map is the product of the relative matching maps indexed by objects of degree \( n \), and in thus a fibration, so \( p_n \) is a fibration as well. Thus, by Proposition C.1.15(i), the induced map \( \lim_F \alpha : \lim_F X \to \lim_F Y \) is a fibration as well. This proves all but the final clause of (ii), which is also left to Exercise C.1.iii.

\[ \square \]

We would like to conclude also that for any pointwise weak equivalence \( \alpha : X \to Y \in \mathcal{M} \) between fibrant diagrams indexed by inverse categories, the induced map \( \lim_F X \to \lim_F Y \) is a weak equivalence. As in the proof of Proposition C.1.15(ii) this requires an intermediate result of independent interest, closely related to Exercise 6.1.iii.

C.1.23. **Proposition.** Let \( \mathcal{M} \) be a category of fibrant objects with fibrations \( \mathcal{F} \) and weak equivalences \( \mathcal{W} \) and let \( \mathcal{I} \) be an inverse category. The category \( \mathcal{M}^\mathcal{I} \) of fibrant diagrams and all natural transformations between them inherits the structure of a category of fibrant objects in which:

- the class of weak equivalences is the class of natural transformations whose components lie in \( \mathcal{W} \);
- the class of fibrations is the class of fibrant natural transformations, those \( \alpha : X \to Y \in \mathcal{M}^\mathcal{I} \) so that for each \( i \in \mathcal{I} \) the map
  \[
  X^i \xrightarrow{n^i} Y^i \times \partial Y^i \times X
  \]
  is in \( \mathcal{F} \);
- the class of trivial fibrations is the class of natural transformations \( \alpha : X \to Y \in \mathcal{M}^\mathcal{I} \) so that for each \( i \in \mathcal{I} \) the map
  \[
  X^i \xrightarrow{\sim} Y^i \times \partial Y^i \times X
  \]
  is in \( \mathcal{F} \cap \mathcal{W} \).

**Proof.** The proof is a very lengthy exercise for the reader, which only entails specializing the corresponding arguments from §C.4 to this “one-sided” case. A proof of a similar result using a mildly different axiomatization can be found in [91, 9.2.4].

The payoff for all this work is that it is now easy to verify the following result.

C.1.24. **Proposition.** Let \( \mathcal{M} \) be a category of fibrant objects and let \( \mathcal{I} \) be an inverse category. Then for any pointwise weak equivalence \( \alpha : X \to Y \in \mathcal{M}^\mathcal{I} \) between fibrant diagrams, the induced map \( \lim_F X \to \lim_F Y \) between the limits is a weak equivalence.

**Proof.** We make use of Proposition C.1.23, which gives the category \( \mathcal{M}^\mathcal{I} \) of fibrant diagrams the structure of a category of fibrant objects. Consider a map \( \alpha : X \to Y \in \mathcal{M}^\mathcal{I} \) in \( \mathcal{F} \) or \( \mathcal{F} \cap \mathcal{W} \). By Proposition C.1.21(ii), this map is the limit composite of a tower of maps, each layer of which is the pullback of a product of the maps that we have assumed lies in \( \mathcal{F} \) or \( \mathcal{F} \cap \mathcal{W} \). Since the classes \( \mathcal{F} \) and \( \mathcal{F} \cap \mathcal{W} \) are closed under product, pullback, and limits of towers, it is now clear that the limit functor preserves these classes. The fact that it also proves the class \( \mathcal{W} \) then follows from Lemma C.1.10. \[ \square \]
Exercises.

C.1.i. Exercise. Show that for any category of fibrant objects $\mathcal{M}$ there is a category of fibrant objects $\mathcal{M}^e$ whose

- objects are cospans $C \xrightarrow{g} A \xleftarrow{f} B$ whose right leg is a fibration in $\mathcal{M}$,
- weak equivalences are pointwise weak equivalences, and
- fibrations are diagrams

\[
\begin{array}{ccc}
C & \xrightarrow{g} & A & \xleftarrow{f} & B \\
\downarrow{r} & & \downarrow{p} & & \downarrow{z} \\
C^\prime & \xrightarrow{\bar{g}} & A^\prime & \xleftarrow{\bar{f}} & B^\prime
\end{array}
\]

in which the maps $r$, $p$, and $q$ are fibrations, as is the induced map $z : B \to A \times_{\bar{A}} B$.

with the requisite limits inherited pointwise from $\mathcal{M}$.

C.1.ii. Exercise. Specialize Proposition C.1.23 to describe the category of fibrant objects structure on the category $\mathcal{M}_{\mathcal{M}^{op}}$ of towers of fibrations in a category of fibrant objects $\mathcal{M}$, and use this to complete the proof of Proposition C.1.15(ii).

C.1.iii. Exercise (C.5.10).

(i) Verify that each leg of the limit cone constructed in Proposition C.1.21(i) is a fibration.

(ii) Conclude that each morphism in the image of a fibrant diagram is a fibration.

(iii) Arguing along the same lines, verify that each component of a fibrant natural transformation is a fibration.

C.1.iv. Exercise. Prove Proposition C.1.23 and determine whether Exercises C.1.i and C.1.ii are special cases of this result.

C.2. Lifting Properties, Weak Factorization Systems, and Leibniz Closure

Fixing two arrows $j$ and $p$ in a category $\mathcal{M}$, we regard any commutative square of the form

\[
\begin{array}{ccc}
\bullet & \xrightarrow{u} & \bullet \\
\downarrow{j} & \bullet & \downarrow{p} \\
\bullet & \xrightarrow{\ell} & \bullet
\end{array}
\]

as presenting a lifting problem between $j$ and $p$, which is solved by constructing a lift: a diagonal morphism $\ell$ making both triangles commute. If every lifting problem between $j$ and $p$ has a solution, we say that $j$ has the left lifting property with respect to $p$ and, equivalently, that $p$ has the right lifting property with respect to $j$. When this is the case, we use the suggestive symbol $j \boxleft p$ to assert this lifting property.

Frequently in abstract homotopy theory a class of maps of interest is characterized by a left or right lifting property with respect to another class or set of maps.

C.2.1. Definition. Let $\mathcal{J}$ be a class of maps in a category $\mathcal{M}$. 490
• Write $\mathcal{J}^\square$ for the class of maps that have the right lifting property with respect to every morphism in $\mathcal{J}$.
• Write $\square \mathcal{J}$ for the class of maps that have the left lifting property with respect to every morphism in $\mathcal{J}$.

C.2.2. **Example.** Definitions 1.1.17 and 1.1.24 characterize the isofibrations and trivial fibrations between quasi-categories by right lifting properties against the sets of maps

$$\{\Lambda^k[n] \hookrightarrow \Delta[n]\}_{n \geq 2, 0 < k < n} \cup \{1 \hookrightarrow \mathbb{I}\} \quad \text{and} \quad \{\partial \Delta[n] \hookrightarrow \Delta[n]\}_{n \geq 0}$$

respectively.

Maps characterized by a right lifting property automatically satisfy various closure properties that may now be familiar.

C.2.3. **Lemma.** Any class of maps $\mathcal{J}^\square$ characterized by a right lifting property contains the isomorphisms and is closed under composition, product, pullback, retract, and limits of towers.

In the statement, “products” and “retracts” refer to limits formed in the category of arrows, while the “pullbacks” are of a map in $\mathcal{J}^\square$ along an arbitrary map. A “tower” refers to a diagram of shape $\alpha^{op}$, where $\alpha$ is a limit ordinal (most likely $\omega$). Closure under limits of towers asserts that if the images of each of the atomic arrows in the indexing category lie in $\mathcal{J}^\square$, then the map from the limit object to the terminal object in the diagram is also in $\mathcal{J}^\square$.

**Proof.** All of the arguments are similar. For instance, suppose $q$ is a pullback of $p \in \mathcal{J}^\square$. By juxtaposing a lifting problem as below-left with the pullback square as below-right, we may solve the composite lifting problem of $j$ against $p$ to obtain the dashed diagonal morphism $\ell$, and then induce a solution $s$ to the lifting problem of $j$ against $q$ via the cone formed by $(v, \ell)$ over the pullback diagram.

![Diagram](https://via.placeholder.com/150)

So $q$ lifts against $\mathcal{J}$ and is therefore in $\mathcal{J}^\square$. \(\Box\)

On account of the dual of Lemma C.2.3, any set of maps in a cocomplete category “cellularly generates” a larger class of maps with the same left lifting property.

C.2.4. **Definition.** Let $\mathcal{J}$ be a class of maps that we think of as “basic cells.” An $\mathcal{J}$-cell complex is a map built as a transfinite composite of pushouts of coproducts of maps in $\mathcal{J}$:

![Diagram](https://via.placeholder.com/150)

The dual notion, a map from the initial object in an $\alpha$-shaped diagram to its limit, is commonly referred to as a “transfinite composite,” or as a “countable composite” in the case $\alpha = \omega$.
The class $\mathcal{J}$-cell of $\mathcal{J}$-cell complexes is said to be **cellularly generated** by a set of maps $\mathcal{J}$. The class $\mathcal{J}$-cof of maps **cofibrantly generated** by a set of maps $\mathcal{J}$ is comprised of those maps obtained as retracts of sequential composites of pushouts of coproducts of those maps.

C.2.5. **Definition.** A **weak factorization system** $(\mathcal{L}, \mathcal{R})$ on a category $\mathcal{M}$ is comprised of two classes of morphisms $\mathcal{L}$ and $\mathcal{R}$ so that

(i) Every morphism in $\mathcal{M}$ may be factored as a morphism in $\mathcal{L}$ followed by a morphism in $\mathcal{R}$.

\[ \bullet \xrightarrow{f} \bullet \]
\[ \mathcal{L} \ni \ell \xrightarrow{r \in \mathcal{R}} \]

(ii) The classes $\mathcal{L}$ and $\mathcal{R}$ respectively have the left and right lifting properties $\mathcal{L} \bowtie \mathcal{R}$ with respect to each other: that is, any commutative square

\[ \begin{array}{ccc} \bullet & \xrightarrow{f} & \bullet \\ \mathcal{L} \ni \ell & & \mathcal{R} \ni r \end{array} \]

admits a diagonal filler as indicated.

(iii) Moreover $\mathcal{L} = \mathcal{R}^\circ$ and $\mathcal{R} = \mathcal{L}^\circ$.

In the presence of a pair of adjoint functors, lifting properties transpose.

C.2.6. **Lemma.** In the presence of any adjunction

\[ \begin{array}{ccc} \mathcal{M} & \xrightarrow{F} & \mathcal{N} \\ \xleftarrow{U} & & \end{array} \]

(i) The lifting problem displayed below left in $\mathcal{N}$ admits a solution if and only if the transposed lifting problem displayed below right admits a solution in $\mathcal{M}$.

\[ \begin{array}{ccc} F A & \xrightarrow{f^\sharp} & X \\ F \ell & \xleftarrow{k^\sharp} & r \end{array} \quad \begin{array}{ccc} A & \xrightarrow{f^\circ} & U X \\ \ell & \xleftarrow{k^\circ} & U r \end{array} \quad \begin{array}{ccc} F B & \xrightarrow{g^\sharp} & Y \\ B & \xrightarrow{g^\circ} & U Y \end{array} \]

(ii) If $\mathcal{M}$ has a weak factorization system $(\mathcal{L}, \mathcal{R})$ and $\mathcal{N}$ has a weak factorization system $(\mathcal{L}', \mathcal{R}')$ then $F$ preserves the left classes if and only if $U$ preserves the right classes:

\[ F \mathcal{L} \subset \mathcal{L}' \iff \mathcal{R} \supset U \mathcal{R}'. \]

The factorizations of Definition C.2.5 are completely irrelevant to (ii) but we have stated this result for weak factorization systems because that is the context in which it will typically be applied.

**Proof.** Exercise C.2.iv. \[ \square \]

Lemma C.2.6(ii) defines the notion of **adjunction of weak factorization systems**, this being an adjoint pair of functors between categories equipped with weak factorization systems so that the left
adjoint preserves the left classes and the right adjoint preserves the right classes. Our aim is now to extend this notion to two-variable adjunctions, which are given by a triple of bifunctors,

\[ \mathcal{V} \times \mathcal{M} \to \mathcal{N}, \quad \mathcal{V}^{\text{op}} \times \mathcal{N} \to \mathcal{M}, \quad \mathcal{M}^{\text{op}} \times \mathcal{N} \to \mathcal{V} \]  

(C.2.7)

which we write using notation that will suggest the most common examples, equipped with a natural isomorphism

\[ \mathcal{N}(V \otimes M, N) \cong \mathcal{M}(M, \{V, N\}) \cong \mathcal{V}(V, \text{hom}(M, N)). \]

The “pushout-product” of a bifunctor \(- \otimes - : \mathcal{V} \times \mathcal{M} \to \mathcal{N}\) defines a bifunctor \(- \bigsqcup \otimes - : \mathcal{V}^2 \times \mathcal{M}^2 \to \mathcal{N}^2\) that we refer to as the “Leibniz tensor” (when the bifunctor \(\otimes\) is called a “tensor”). The “Leibniz cotensor” and “Leibniz hom”

\[ \cong - \bigsqcup - : (\mathcal{V}^2)^{\text{op}} \times \mathcal{N}^2 \to \mathcal{M}^2 \quad \text{and} \quad \cong \text{hom}(-, -) : (\mathcal{M}^2)^{\text{op}} \times \mathcal{N}^2 \to \mathcal{V}^2 \]

are defined dually, using pullbacks in \(\mathcal{M}\) and \(\mathcal{V}\) respectively.

C.2.8. Definition (Leibniz tensors and cotensors). Given a bifunctor \(- \otimes - : \mathcal{V} \times \mathcal{M} \to \mathcal{N}\) valued in a category with pushouts, the Leibniz tensor of a map \(k : I \to J\) in \(\mathcal{V}\) and a map \(\ell : A \to B\) in \(\mathcal{M}\) is the map \(k \bigsqcup \ell\) in \(\mathcal{N}\) induced by the pushout diagram below-left:

In the case of a bifunctor \(- \bigsqcup - : \mathcal{V}^{\text{op}} \times \mathcal{N} \to \mathcal{M}\) contravariant in one of its variables valued in a category with pullbacks, the Leibniz cotensor of a map \(k : I \to J\) in \(\mathcal{V}\) and a map \(m : X \to Y\) in \(\mathcal{N}\) is the map \([k, m]\) induced by the pullback diagram above right.

C.2.9. Proposition. The Leibniz construction preserves:

(i) structural isomorphisms: a natural isomorphism

\[ X \ast (Y \otimes Z) \cong (X \times Y) \square Z \]

between suitably composable bifunctors extends to a natural isomorphism

\[ f \ast (g \otimes h) \cong (f \times g) \boxdot h \]

between the corresponding Leibniz products;

(ii) adjointness: if \((\otimes, \{\}, \text{hom})\) define a two-variable adjunction, then the Leibniz functors \((\otimes, \{\}, \text{hom})\) define a two-variable adjunction between the corresponding arrow categories;

(iii) colimits in the arrow category: if \(\otimes : \mathcal{V} \times \mathcal{M} \to \mathcal{N}\) is cocontinuous in either variable, then so is \(\otimes : \mathcal{V}^2 \times \mathcal{M}^2 \to \mathcal{N}^2\);

(iv) pushouts: if \(\otimes : \mathcal{V} \times \mathcal{M} \to \mathcal{N}\) is cocontinuous in its second variable, and if \(g'\) is a pushout of \(g\), then \(f \otimes g'\) is a pushout of \(f \otimes g\).

⁵There is an analogous generalization to \(n\)-variable adjunctions that can be found in [27, §4].
(v) composition, in a sense: the Leibniz tensor \( f \odot (h \cdot g) \) factors as a composite of a pushout of \( f \odot g \) followed by \( f \odot h \)

\[
\begin{array}{cccc}
I \otimes A & \rightarrow & I \otimes B & \rightarrow & I \otimes C \\
& \downarrow_{f \otimes A} & & \downarrow_{r} & \\
J \otimes A & \rightarrow & \bullet & \rightarrow & \bullet \\
& \downarrow_{1 \otimes g} & & \downarrow_{f \otimes C} & \\
J \otimes B & \rightarrow & \bullet & \rightarrow & \bullet \\
& \downarrow_{f \otimes (h \cdot g)} & & \downarrow_{f \otimes h} & \\
J \otimes C & \\
\end{array}
\]

(vi) cell complex structures: if \( f \) and \( g \) may be presented as cell complexes with cells \( f_\alpha \) and \( g_\beta \), respectively, and if \( \otimes \) is cocontinuous in both variables, then \( f \odot g \) may be presented as a cell complex with cells \( f_\alpha \odot g_\beta \).

**Proof.** The components of the induced structural isomorphism between Leibniz products are instances of the given structure isomorphism and hence invertible, proving (i). For (ii), by naturality of the isomorphisms defining a two-variable adjunction \((\otimes, \{\}, \hom)\), each of the squares below commutes if and only if the other two do, under the hypothesis that the horizontal arrows given the same names in each diagram are transposes:

\[
\begin{array}{cccc}
J \otimes A \cup I \otimes A & \rightarrow & I \otimes B & \rightarrow & I \otimes C \\
& \downarrow_{(u,v)} & & \downarrow_{(I,Y)} & \\
J \otimes B & \rightarrow & \bullet & \rightarrow & \bullet \\
& \downarrow_{(w,v)} & & \downarrow_{f \otimes (h \cdot g)} & \\
J \otimes C & \\
\end{array}
\]

This transposition correspondence extends to solutions to the lifting problems presented by these squares; see Exercise C.2.v.

Property (iii) is immediate since limits or colimits in arrow categories are computed pointwise. For (iv), consider the commutative cube:

\[
\begin{array}{cccc}
I \otimes A & \rightarrow & I \otimes C & \rightarrow & I \otimes D \\
& \downarrow_{f \otimes A} & & \downarrow_{1 \otimes C} & \\
J \otimes A & \rightarrow & \bullet & \rightarrow & \bullet \\
& \downarrow_{1 \otimes g} & & \downarrow_{f \otimes C} & \\
J \otimes B & \rightarrow & \bullet & \rightarrow & \bullet \\
& \downarrow_{f \otimes g} & & \downarrow_{f \otimes g'} & \\
J \otimes D & \\
\end{array}
\]

Since \( I \otimes \cdot \) and \( J \otimes \cdot \) preserve the pushout defining \( g' \) as a pushout of \( g \), the top and bottom faces of the cube are pushouts. The squares defining the domains of the Leibniz tensors define pushouts inside the left and right-hand faces. It follows by pushout composition and cancelation that \( f \odot g' \) is a pushout of \( f \odot g \) as claimed.
The displayed diagram in (v) proves the assertion made there, so it remains only to prove (vi). First note that pushouts of transfinite composites of pushouts are again transfinite composites of pushouts and transfinite composites of transfinite composites are transfinite composites, so it suffices to work one variable at a time and prove that \( f \otimes - \) preserves cell complex presentations for \( g \). To that end, suppose \( g \) is a \( \alpha \)-composite of maps \( g_i \) each of which are pushouts of a coproduct of maps \( g'_i = \coprod_j g'_{i,j} \). We may promote this colimit to the arrow category to regard \( g = g_{0,\alpha} \) as the colimit of the diagram \( g_{-,\alpha}: \alpha \to M^2 \) with one-step maps:

\[
\begin{array}{ccc}
\bullet & \xrightarrow{g_i} & \bullet \\
\downarrow & & \downarrow \\
\bullet & = & \bullet
\end{array}
\]

Similarly, the pushout square defining \( g_i \) from \( g'_i \) can be promoted to a pushout square in the arrow category:

\[
\begin{array}{ccc}
\bullet & \xrightarrow{g'_i} & \bullet \\
\downarrow & & \downarrow \\
\bullet & \xrightarrow{\coprod_j g'_{i,j}} & \bullet \\
\downarrow & & \downarrow \\
\bullet & \xrightarrow{\coprod_j g'_{i,j}} & \bullet
\end{array}
\]

We interpret this cube as presenting the square in the front face as a pushout of the square in the back face, which decomposes as a coproduct of similar squares, one for each component of \( g'_i = \coprod_j g'_{i,j} \). In this way we see that \( g = g_{0,\alpha} \) is the domain component of the colimit of a diagram \( \alpha \to M^2 \), each step of which is a pushout of a coproduct of maps in the arrow category. Now \( f \otimes -: M^2 \to N^2 \) preserves colimits in the arrow category, and the domain functor \( \text{dom}: N^2 \to N \) preserves colimit as well. Thus, \( f \otimes g \) is a colimit of an \( \alpha \)-sequence of pushouts of coproducts of the maps \( f \otimes g_{i,j} \). \( \square \)

More details establishing these assertions are given in \([102, \S\S 4-5]\).

C.2.10. DEFINITION. Let \( V, M, \) and \( N \) be cocomplete categories each equipped with weak factorization systems \((L, R)\), \((L', R')\), and \((L'', R'')\), respectively. A left Leibniz bifunctor is a bifunctor

\[
\otimes: V \times M \to N
\]

that is

(i) cocontinuous in each variable separately, and

(ii) has the Leibniz property: \( \otimes \)-pushout products of a map in \( L \) with a map in \( L' \) are in \( L'' \).

Dually, a bifunctor between complete categories equipped with weak factorization systems is a right Leibniz bifunctor if it is continuous in each variable separately and if pullback cotensors of maps in the right classes land in the right class. We most frequently apply this definition in the case of a bifunctor

\[
\{-, -\}: V^{\text{op}} \times N \to M
\]
that is contravariant in one of its variables, in which we case the relevant hypotheses are that \( \mathcal{V} \) is cocomplete and colimits in the first variable are carried to limits in \( \mathcal{M} \), and furthermore the Leibniz cotensor of a map in \( \mathcal{L} \) with a map in \( \mathcal{R}'' \) defines a map in \( \mathcal{R}' \). The nature of the duality between left and right Leibniz bifunctors is somewhat subtle to articulate. We leave this as a puzzle for the reader, with the hint to see \([27]\).

C.2.11. **Lemma.** If the bifunctors

\[
\mathcal{V} \times \mathcal{M} \overset{\otimes}{\rightarrow} \mathcal{N}, \quad \mathcal{V}^{\text{op}} \times \mathcal{N} \overset{\{-,-\}}{\rightarrow} \mathcal{M}, \quad \text{and} \quad \mathcal{M}^{\text{op}} \times \mathcal{N} \overset{\text{hom}}{\rightarrow} \mathcal{V}
\]

define a two-variable adjunction, and \((\mathcal{L}, \mathcal{R}), (\mathcal{L}', \mathcal{R}'), (\mathcal{L}'', \mathcal{R}'')\) are three weak factorization systems on \( \mathcal{V}, \mathcal{M}, \) and \( \mathcal{N} \) respectively, then the following are equivalent

(i) \( \otimes: \mathcal{V} \times \mathcal{M} \to \mathcal{N} \) defines a left Leibniz bifunctor.

(ii) \( \{-,-\}: \mathcal{V}^{\text{op}} \times \mathcal{N} \to \mathcal{M} \) defines a right Leibniz bifunctor.

(iii) \( \text{hom}: \mathcal{M}^{\text{op}} \times \mathcal{N} \to \mathcal{V} \) defines a right Leibniz bifunctor.

When these conditions are satisfied, we say that \((\otimes, \{-,-\}, \text{hom})\) defines a **Leibniz two-variable adjunction**.

**Proof.** The presence of the adjoints ensures that each of the bifunctors satisfy the required (co)continuity hypotheses. Note that, for instance, \( \mathcal{L} \otimes \mathcal{L}' \subset \mathcal{L}'' \) if and only if \( \mathcal{L} \otimes \mathcal{L}' \sqsubseteq \mathcal{R}'' \). Now the equivalence of the three statements follows from the equivalence of the following three lifting properties:

\[
\mathcal{L} \otimes \mathcal{L}' \sqsubseteq \mathcal{R}'' \iff \mathcal{L}' \sqsubseteq \{\mathcal{L}, \mathcal{R}'\} \iff \mathcal{L} \sqsubseteq \text{hom}(\mathcal{L}', \mathcal{R}''),
\]

the proof of which is left to Exercise C.2.v.

C.2.12. **Lemma.** For any category \( \mathcal{M} \) with products and coproducts that is equipped with a weak factorization system \((\mathcal{L}, \mathcal{R})\) the set-tensor, set-cotensor, and hom

\[
* : \text{Set} \times \mathcal{M} \to \mathcal{M}, \quad \{-,-\} : \text{Set}^{\text{op}} \times \mathcal{M} \to \mathcal{M}, \quad \text{and} \quad \text{hom} : \mathcal{M}^{\text{op}} \times \mathcal{M} \to \text{Set}
\]

respectively define a Leibniz two-variable adjunction relative to the (monomorphism, epimorphism) weak factorization system on \( \text{Set} \).

**Proof.** By Lemma C.2.11, it suffices to prove any one of these bifunctors is Leibniz. When \( A \hookrightarrow B \) is a monomorphism in \( \text{Set} \), the Leibniz tensor with \( f: X \to Y \) decomposes as a coproduct of maps that are manifestly in \( \mathcal{L} \).

\[
\begin{array}{c}
A \times X \leftarrow B \times X \cong A \times X \coprod B \setminus A \times X \\
A \times Y \longrightarrow A \times Y \coprod B \setminus A \times X \\
A \setminus f \downarrow \quad \downarrow \quad \downarrow \quad \downarrow B \setminus f \\
A \setminus f \coprod \text{id} \\
B \setminus f \\
\end{array}
\]

A slicker proof is also possible. Because every monomorphism may be presented as a cell complex built from a single cell \( \emptyset \hookrightarrow 1 \), by Proposition C.2.9(vi), it suffices to consider Leibniz tensor with the
generating monomorphism $\emptyset \hookrightarrow 1$. But note that the functor
\[
\mathcal{M}^2 \xrightarrow{(\emptyset \hookrightarrow 1)^*} \mathcal{M}^2
\]
is naturally isomorphic to the identity, which certainly preserves the left class $\mathcal{L}$.

C.2.14. REMARK. By Lemma C.2.12, $\text{hom} : \mathcal{M}^{\text{op}} \times \mathcal{M} \to \mathcal{S e t}$ is right Leibniz, meaning that for any $\ell \in \mathcal{L}$ and $r \in \mathcal{R}$, the morphism
\[
\mathcal{M}(\text{cod } \ell, \text{dom } r) \xrightarrow{r \circ \ell} \mathcal{M}(\text{dom } \ell, \text{dom } r) \times \mathcal{M}(\text{dom } \ell, \text{cod } r) \mathcal{M}(\text{cod } \ell, \text{cod } r)
\]
is an epimorphism. The target of this map is the set of commutative squares in $\mathcal{M}$ from $\ell$ to $r$, while the fiber over any element is the set of solutions to the lifting problem so-presented. The fact that this is an epimorphism re-expresses the lifting property $\mathcal{L} \square \mathcal{R}$.

Exercises.
C.2.i. EXERCISE. Finish the proof of Lemma C.2.3.
C.2.ii. EXERCISE.
(i) Prove the “retract argument”: Suppose $f = r \circ \ell$ and $f$ has the left lifting property with respect to its right factor $r$. Then $f$ is a retract of its left factor $\ell$.
(ii) Conclude that in the presence of axioms (i) and (ii) of Definition C.2.5, that axiom (iii) may be replaced by the hypothesis that the classes $\mathcal{L}$ and $\mathcal{R}$ are closed under retracts.
C.2.iii. EXERCISE.
(i) Suppose $\mathcal{M}$ is a category with products, pullbacks, and limits of towers equipped with a weak factorization system $(\mathcal{L}, \mathcal{R})$, and let $\mathcal{I}$ be an inverse category. Prove that the category of diagrams $\mathcal{M}^I$ has a weak factorization system whose left class is comprised of those maps whose components are in $\mathcal{L}$ and whose right class is comprised of those maps $\alpha : X \to Y$ so that for each $i \in I$, the relative matching map $\hat{m}_i : \partial_i X \times_{\partial_i Y} Y_i$ lies in $\mathcal{R}$.
(ii) Give a new proof that $\text{lim} : \mathcal{M}^I \to \mathcal{M}$ preserves fibrations and trivial fibrations under the additional hypothesis that the classes $\mathcal{F}$ and $\mathcal{F} \cap \mathcal{W}$ of $\mathcal{M}$ are the right classes of weak factorization systems.
C.2.iv. EXERCISE. Prove Lemma C.2.6
C.2.v. EXERCISE. Given a two variable adjunction (C.2.7) and classes of maps $\mathcal{A}, \mathcal{B}, \mathcal{C}$ in $\mathcal{V}, \mathcal{M}, \mathcal{N}$, respectively, prove that the following lifting properties are equivalent
\[
\mathcal{A} \otimes \mathcal{B} \otimes \mathcal{C} \iff \mathcal{B} \otimes [\mathcal{A}, \mathcal{C}] \iff \mathcal{A} \otimes \text{hom}(\mathcal{B}, \mathcal{C}).
\]
C.3. Model Categories and Quillen Functors

The following reformulation of Quillen’s definition of “closed model categories” [90, I.5.1] was given by Joyal and Tierney [62, 7.7], who prove that a category $(\mathcal{M}, \mathcal{W})$ with weak equivalences satisfying the two-of-three property admits a model structure just when there exist classes $\mathcal{C}$ and $\mathcal{F}$ that define a pair of weak factorization systems as follows:
C.3.1. **Definition** (model category). A **model structure** on a category \( \mathcal{M} \) with all small limits and colimits consists of three classes of maps — the **weak equivalences** \( \mathcal{W} \) denoted “\( \sim \)”, which must satisfy the two-of-three property, the **cofibrations** \( \mathcal{C} \) denoted “\( \rightarrow \)”, and the **fibrations** \( \mathcal{F} \) denoted “\( \twoheadrightarrow \)” — so that \((\mathcal{C}, \mathcal{F} \cap \mathcal{W})\) and \((\mathcal{C} \cap \mathcal{W}, \mathcal{F})\) each define weak factorization systems on \( \mathcal{M} \).

As alluded to in Example C.1.4, we can now define the fibrant objects in a model category, which inspired Definition C.1.1.

**C.3.2. Definition.** In a model category \( \mathcal{M} \) an object \( X \) is **fibrant** just when the unique map \( X \to 1 \) to the terminal object is a fibrant and **cofibrant** just when the unique map \( \emptyset \to X \) from the initial object is a cofibration. By factoring the unique maps, any object \( X \) has a **cofibrant replacement** \( QX \) and a **fibrant replacement** \( RX \) constructed as follows:

\[
\emptyset \quad \xrightarrow{!} \quad QX \quad \xrightarrow{!} \quad X \quad \xrightarrow{!} \quad RX \quad \xrightarrow{!} \quad * \]

Note that Definitions C.2.5 and C.3.1 are self-dual: if \( (\mathcal{L}, \mathcal{R}) \) defines a weak factorization system on \( \mathcal{M} \) then \( (\mathcal{R}, \mathcal{L}) \) defines a weak factorization system on \( \mathcal{M}^{op} \). Thus all general theorems about the right classes \( \mathcal{F} \) of fibrations and \( \mathcal{F} \cap \mathcal{W} \) of **trivial fibrations** “\( \twoheadrightarrow \)”, imply the dual results involving the left classes \( \mathcal{C} \) of cofibrations and \( \mathcal{C} \cap \mathcal{W} \) of **trivial cofibrations** “\( \hookrightarrow \)”.

Note also that since either class of a weak factorization system determines the other, the trivial cofibrations can be defined without reference to either the cofibrations or weak equivalences as those maps that have the left lifting property with respect to the fibrations, and dually the trivial fibrations are precisely those maps that have the right lifting property with respect to the cofibrations.

C.3.3. **Definition.** A functor between model categories is

- **left Quillen** if it preserves cofibrations, trivial cofibrations, and cofibrant objects, and
- **right Quillen** if it preserves fibrations, trivial fibrations, and fibrant objects.

Left Quillen functors admit left derived functors while right Quillen functors admit right derived functors. We leave a full account of this to other authors [98, §§2.1-2] so as to avoid defining these terms, but an important component of the “derivability” of Quillen functors is captured by the following result:

**C.3.4. Lemma.** Any left Quillen functor between model categories preserves weak equivalences between cofibrant objects, while any right Quillen functor preserves weak equivalences between fibrant objects.

**Proof.** For right Quillen functors this follows directly from Lemma C.1.10 and Example C.1.4. The result for left Quillen functors is dual. □

⁶There is one axiom in standard definition of a model category — the closure of weak equivalences under retracts — that is not obviously packaged into these hypotheses, but this is a consequence of the axioms given here [62, 7.8].
Most left Quillen functors are “cocontinuous,” preserving all colimits, while most right Quillen functors are “continuous,” preserving all limits; when this is the case there is no need to separately assume that cofibrant or fibrant objects are preserved. In fact, Quillen functors commonly occur as an adjoint pair:

C.3.5. Definition. Consider an adjunction between a pair of model categories.

\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\sim} & \mathcal{N} \\
\downarrow F & \quad & \downarrow U \\
\mathcal{N} & \xleftarrow{\sim} & \mathcal{M}
\end{array}
\]

By Lemma C.2.6 the following are equivalent, defining a Quillen adjunction.

(i) The left adjoint \( F \) is left Quillen.
(ii) The right \( U \) is right Quillen.
(iii) The left adjoint preserves cofibrations and the right adjoint preserves fibrations.
(iv) The left adjoint preserves trivial fibrations and the right adjoint preserves trivial fibrations.

C.3.6. Lemma. For a Quillen adjunction

\[
\begin{array}{ccc}
\mathcal{M} & \xrightarrow{\sim} & \mathcal{N} \\
\downarrow F & \quad & \downarrow U \\
\mathcal{N} & \xleftarrow{\sim} & \mathcal{M}
\end{array}
\]

the following are equivalent and characterize those Quillen adjunctions that define Quillen equivalences:

(i) For every cofibrant object \( M \in \mathcal{M} \) and every fibrant object \( N \in \mathcal{N} \), a map \( FM \to N \) is a weak equivalence in \( \mathcal{N} \) if and only if its transpose \( M \to UN \) is a weak equivalence in \( \mathcal{M} \).
(ii) (a) For every cofibrant object \( M \in \mathcal{M} \), the derived unit

\[
M \xrightarrow{\eta} UFM \to \text{URFM}
\]

defined by composing the unit with fibrant replacement is a weak equivalence.

(b) For every fibrant object \( N \in \mathcal{N} \), the derived counit

\[
FQUN \to FUN \xleftarrow{\epsilon} N
\]

defined by composing the counit with cofibrant replacement is a weak equivalence.

Proof. Assume (i) and consider a cofibrant object \( M \in \mathcal{M} \) and a fibrant object \( N \in \mathcal{N} \). The derived unit and counit are respectively tranposes of the fibrant replacement and cofibrant replacement maps

\[
FM \to RFM \quad \text{and} \quad QUN \to UN
\]

By Definition C.3.2 these maps are weak equivalences, and since \( M \) and \( QUN \) are cofibrant while \( RFM \) and \( N \) are fibrant, (i) tells us that the derived unit and counit must be weak equivalences as well.

Now assume (ii) and consider a weak equivalence \( f: FM \Rightarrow N \) where \( M \) is cofibrant and \( N \) is fibrant. Applying the right adjoint and fibrant replacement, we obtain a commutative diagram

\[
\begin{array}{ccc}
M \xrightarrow{\eta} UFM & \xrightarrow{UF} & \text{URFM} \\
\downarrow {f} & \quad & \downarrow {URf} \\
UN & \xrightarrow{\sim} & \text{URN}
\end{array}
\]
By Lemma C.3.4, the right and bottom maps are weak equivalences and the hypothesis (ii)a tells us that the top composite is as well. Thus the transpose $f^\# : M \Rightarrow UN$ is a weak equivalence as well. Dually, (ii)b implies that weak equivalences $M \Rightarrow UN$ transpose to weak equivalences $FM \Rightarrow N$. □

We now introduce a pair of model structures on diagram categories that are designed to ensure that the diagonal functor $\Delta : \mathcal{M} \rightarrow \mathcal{M}^\mathcal{J}$ is respectively right or left Quillen, so that the colimit and limit functors, respectively, are left or right Quillen. The corresponding left and right derived functors then define the homotopy colimit and homotopy limit functors.

C.3.7. Definition. Let $\mathcal{M}$ be a model category and let $\mathcal{J}$ be a small category.

(i) The projective model structure on $\mathcal{M}^\mathcal{J}$ has weak equivalences and fibrations defined pointwise in $\mathcal{M}$.

(ii) The injective model structure on $\mathcal{M}^\mathcal{J}$ has weak equivalences and cofibrations defined pointwise in $\mathcal{M}$.

When the model category $\mathcal{M}$ is combinatorial or more generally accessible, the projective and injective model structures always exist [51]. Of course, the projective and injective model structures might happen to exist on $\mathcal{M}^\mathcal{J}$, perhaps for particular diagram shapes $\mathcal{J}$, in the absence of these hypotheses.

A Quillen two-variable adjunction is a two-variable adjunction in which the left adjoint is a left Quillen bifunctor while the right adjoints are both right Quillen bifunctors. By Exercise C.2.v, any one of these conditions implies the other two:

C.3.8. Definition. A two-variable adjunction

$$\mathcal{V} \times \mathcal{M} \overset{\otimes}{\rightarrow} \mathcal{N}, \quad \mathcal{V}^{\text{op}} \times \mathcal{N} \overset{\{-,-\}}{\rightarrow} \mathcal{M}, \quad \mathcal{M}^{\text{op}} \times \mathcal{N} \overset{\text{hom}}{\rightarrow} \mathcal{V}$$

between model categories $\mathcal{V}$, $\mathcal{M}$, and $\mathcal{N}$ defines a Quillen two-variable adjunction if any, and hence all, of the following equivalent conditions are satisfied:

(i) The functor $\otimes : \mathcal{V}^2 \times \mathcal{M}^2 \rightarrow \mathcal{N}^2$ carries any pair comprised of a cofibration in $\mathcal{V}$ and a cofibration in $\mathcal{M}$ to a cofibration in $\mathcal{N}$ and furthermore this cofibration is a weak equivalence if either of the domain cofibrations are.

(ii) The functor $\{-,-\} : (\mathcal{V}^2)^{\text{op}} \times \mathcal{N}^2 \rightarrow \mathcal{M}^2$ carries any pair comprised of a cofibration in $\mathcal{V}$ and a fibration in $\mathcal{N}$ to a fibration in $\mathcal{N}$ and furthermore this fibration is a weak equivalence if either of the domain maps are.

(iii) The functor $\text{hom} : (\mathcal{M}^2)^{\text{op}} \times \mathcal{N}^2 \rightarrow \mathcal{V}^2$ carries any pair comprised of a cofibration in $\mathcal{M}$ and a fibration in $\mathcal{N}$ to a fibration in $\mathcal{V}$ and furthermore this fibration is a weak equivalence if either of the domain maps are.

C.3.9. Remark. Definition C.3.8, asserts that a two-variable adjunction is Quillen if and only if its left adjoint $\otimes : \mathcal{V} \times \mathcal{M} \rightarrow \mathcal{N}$ is a left Quillen bifunctor: a bifunctor that is left Leibniz with respect to seven of the eight possible choices of constituent weak factorization systems, the exception the choice of $(\mathcal{C}, \mathcal{F} \cap \mathcal{W})$ for both $\mathcal{V}$ and $\mathcal{M}$ and $(\mathcal{C} \cap \mathcal{W}, \mathcal{F})$ for $\mathcal{N}$.

Quillen’s axiomatization of the additional properties enjoyed by his model structure on the category of simplicial sets has been generalized by Hovey [55, §4.2] to define the notions of monoidal model category and enriched model category. We specialize the former to the cartesian closed categories of §A.1 as those are the only cases needed here. If $\mathcal{V}$ has a model structure and also is a cartesian closed category it is natural to ask that these structures be compatible in some way.
C.3.10. Definition. A **cartesian closed model category** is a cartesian closed category \((\mathcal{V}, \times, 1)\) with a model structure so that

(i) the cartesian product and internal hom define a Quillen two-variable adjunction and

(ii) furthermore so that the map

\[ Q1 \times \mathcal{V} \to 1 \times \mathcal{V} \cong \mathcal{V} \]

are is a weak equivalence whenever \(\mathcal{V}\) is cofibrant. 

Then:

C.3.11. Definition. If \(\mathcal{V}\) is a cartesian closed model category a **\(\mathcal{V}\)-model category** is a model category \(\mathcal{M}\) that is

(i) tensored, cotensored, and \(\mathcal{V}\)-enriched in such a way that \((\otimes, [,], \text{hom})\) is a Quillen two-variable adjunction and

(ii) the maps

\[ Q1 \otimes m \to 1 \otimes m \cong m \]

are weak equivalences if \(m\) is cofibrant. 

C.3.12. Lemma. If \(\mathcal{M}\) is a \(\mathcal{V}\)-model category, then for any cofibrant object \(M\) and fibrant object \(N\) in \(\mathcal{M}\), \(\text{hom}(M, N)\) is a fibrant object in \(\mathcal{V}\). More generally, for any cofibrant object \(M\) and fibration \(p: N \to P\), the induced map \(p_*: \text{hom}(M, N) \to \text{hom}(M, P)\) is a fibration in \(\mathcal{V}\).

Proof. By Proposition A.5.5—which implies, for the terminal object \(1 \in \mathcal{M}\) and any \(M \in \mathcal{V}\), that \(\text{hom}(M, 1) \cong 1\) is terminal in \(\mathcal{V}\)—the second statement subsumes the first. By Exercise C.2.v, the lifting problem below-left for any trivial cofibration \(i\) in \(\mathcal{V}\) transposes to the lifting problem below-right

\[
\begin{array}{ccc}
U & \longrightarrow & \text{hom}(M, N) \\
i & \downarrow & \downarrow p_* \\
V & \longrightarrow & \text{hom}(M, P)
\end{array}
\quad \begin{array}{ccc}
U \otimes M & \longrightarrow & N \\
i \otimes M & \downarrow i & \downarrow p \\
V \otimes M & \longrightarrow & P
\end{array}
\]

By Exercise C.3.iii, since \(\mathcal{M}\) is cofibrant, \(- \otimes M: \mathcal{V} \to \mathcal{M}\) is left Quillen, so \(i \otimes M\) is a trivial cofibration in \(\mathcal{M}\) and since \(p: N \to P\) is a fibration, a solution to the lifting problem exists. \(\square\)

The following result was formulated by Gambino \[44\] in the context of a model category enriched over Quillen’s cartesian closed model structure on simplicial sets, but its proof applies in greater generality.

C.3.13. Theorem. If \(\mathcal{M}\) is a \(\mathcal{V}\)-model category and \(\mathcal{J}\) is a small category, then the weighted colimit functor

\[ \text{colim}^\mathcal{J} - : \mathcal{V}^\mathcal{J} \times \mathcal{M}^{\mathcal{J}^{\text{op}}} \to \mathcal{M} \]

is left Quillen if the domain categories have the (injective, projective) or (projective, injective) model structure. Similarly, the weighted limit functor

\[ \text{lim}^\mathcal{J} - : (\mathcal{V}^{\mathcal{J}})^{\text{op}} \times \mathcal{M}^{\mathcal{J}} \to \mathcal{M} \]

is right Quillen if the domain categories have the (projective, projective) or (injective, injective) model structure.

---

1If \(1 \in \mathcal{V}\) is cofibrant, it suffices to require only the first condition; see Exercise C.3.iii.

2Again, by Exercise C.3.iii this condition is unnecessary if \(1 \in \mathcal{V}\) is cofibrant.
Proof. By Definition C.3.8 we can prove both statements in adjoint form. The weighted colimit bifunctor of Definition A.6.5 has a right adjoint (used to express the defining universal property of the weighted colimit)

\[ \text{hom}(\cdot, \cdot) : (\mathcal{M}^{\mathcal{J}^{\text{op}}})^{\text{op}} \times \mathcal{M} \to \mathcal{V}^{\mathcal{J}} \]

which sends \( F \in \mathcal{M}^{\mathcal{J}^{\text{op}}} \) and \( m \in \mathcal{M} \) to \( \text{hom}(F\cdot, m) \in \mathcal{V}^{\mathcal{J}} \).

To prove the statement when \( \mathcal{V}^{\mathcal{J}} \) has the projective and \( \mathcal{M}^{\mathcal{J}^{\text{op}}} \) has the injective model structure, we must show that this is a right Quillen bifunctor with respect to the pointwise (trivial) cofibrations in \( \mathcal{M}^{\mathcal{J}^{\text{op}}} \), (trivial) fibrations in \( \mathcal{M} \), and pointwise (trivial) fibrations in \( \mathcal{V}^{\mathcal{J}} \). Because the limits involved in the definition of right Quillen bifunctors are also formed pointwise, this follows immediately from the corresponding property of the enriched hom bifunctor, which was part of the definition of an enriched model category. The other cases are similar. \( \square \)

C.3.14. Digression (on the construction of homotopy colimits). In a model category, the terms homotopy colimit and homotopy limit refer to the derived functors of the colimit and limit functors. The upshot of Theorem C.3.13 is that there are two approaches to constructing a homotopy colimit: “fattening up the diagram” — for instance, by requiring that its objects are cofibrant and its morphisms are cofibrations — or “fattening up the weight” — typically by taking a cofibrant replacement of the terminal weight [98, §11.5]. Lemmas 6.3.7 and 6.3.11 can be understood as examples of the general equivalence between these two approaches.

We single out one of many consequences of Theorem C.3.13, of interest because the flexible weights of Definition 6.2.1 are precisely the cofibrant objects in the projective model structure on the category of weights defines relative to the Joyal model structure on simplicial sets.

C.3.15. Corollary. If \( \mathcal{M} \) is a \( \mathcal{V} \)-model category, then for any diagram \( F \in \mathcal{M}^{\mathcal{J}} \) whose objects are all fibrant and any projective cofibrant weight \( W \in \mathcal{V}^{\mathcal{J}} \), the weighted limit is a fibrant object.

Proof. By Theorem C.3.13, the weighted limit functor \( \text{lim}^{\mathcal{J}} - : (\mathcal{V}^{\mathcal{J}})^{\text{op}} \times \mathcal{M}^{\mathcal{J}} \to \mathcal{M} \) is right Quillen with respect to the projective model structure on the category of weights and the projective model structure on the category of diagrams. Since right Quillen bifunctors preserve fibrant objects, it follows that the limit of a pointwise fibrant diagram weighted by a projective cofibrant weight is fibrant. \( \square \)

Finally, we will make use of the following theorem which enables the change of base of enrichment for model categories extending the results of §A.7. The premises of Theorem C.3.16 are the obvious extension of the premises of Proposition A.7.6 to the enriched model category context, but the conclusion only allows us to transfer enrichments in the direction of the right adjoint because an enriched model category must also be tensored and cotensored and these properties only transfer in that direction.

The result below is a specialization of a more general theorem proven in [48, 3.8] to the cartesian closed bases for enrichment that we have been considering.

C.3.16. Theorem. Consider a Quillen adjunction between cartesian closed model categories in which the left adjoint preserves finite products:

\[ \mathcal{V} \underbrace{\xrightarrow{F} \mathcal{W}}_{U} \]

502
Then any $\mathcal{W}$-model category admits the structure of a $\mathcal{V}$-model category with the same underlying unenriched model category with enriched homs, cotensors, and tensors defined by:

$$\text{hom}_\mathcal{V}(M, N) := U \text{hom}_\mathcal{W}(M, N), \quad V \otimes M := FV \otimes M, \quad \text{and} \quad M^V := M^{FV}.$$ 

**Proof.** By Proposition A.7.7 these definitions make $\mathcal{W}$ into a tensored and cotensored $\mathcal{V}$-enriched category, and Lemma A.7.9 observed that change of base along the right adjoint of a finite-product-preserving adjunction preserves underlying 1-categories. It remains only to verify that the functors underlying the $\mathcal{V}$-enriched hom, tensor, and cotensor define a Quillen two-variable adjunction, but this follows easily from the cartesian closure of the model categories $\mathcal{V}$ and $\mathcal{W}$ and the fact that $F \dashv U$ is Quillen. \qed

**Exercises.**

C.3.i. **Exercise.** Verify that the full subcategory of fibrant objects in a model category defines a category of fibrant objects with $\mathcal{W}$ the class of weak equivalences and $\mathcal{F}$ the class of fibrations between fibrant objects.

C.3.ii. **Exercise.** Verify that a model structure on $\mathcal{M}$, if it exists, is uniquely determined by any of the following data:

1. the cofibrations and weak equivalences,
2. the fibrations and weak equivalences,
3. the cofibrations and fibrations,
4. the trivial cofibrations and trivial fibrations.⁹

C.3.iii. **Exercise.**

(i) Prove that if $- \otimes -: \mathcal{V} \times \mathcal{M} \to \mathcal{N}$ is a left Quillen bifunctor and $V \in \mathcal{V}$ is cofibrant then $V \otimes -: \mathcal{M} \to \mathcal{N}$ is a left Quillen functor.

(ii) Conclude that the second conditions of Definitions C.3.10 and C.3.11 are unnecessary if $1 \in \mathcal{V}$ is cofibrant.

C.3.iv. **Exercise.** In a locally small category $\mathcal{M}$ with products and coproducts the hom bifunctor is part of a two-variable adjunction:

$$- \star -: \text{Set} \times \mathcal{M} \to \mathcal{M}, \quad [-, -]: \text{Set}^{\text{op}} \times \mathcal{M} \to \mathcal{M}, \quad \text{hom}: \mathcal{M}^{\text{op}} \times \mathcal{M} \to \text{Set}.$$ 

Equipping $\text{Set}$ with the model structure whose weak equivalences are all maps, whose cofibrations are monomorphisms, and whose fibrations are epimorphisms, prove that

(i) $\text{Set}$ is a cartesian closed model category.

(ii) Any model category $\mathcal{M}$ is a $\text{Set}$-model category.

C.4. **Reedy Categories and Canonical Presentations**

In this section, we describe a particular structure borne by certain small categories $\mathcal{A}$ first exploited by Reedy to prove homotopical results about the category of $\mathcal{A}$-indexed diagrams [94]. Our primary examples—the ordinal category $\Delta_+$, inverse categories, their opposites, and products of these—are...
all (strict) Reedy categories as defined by Kan, so we confine our attention to this special case. This theory has been usefully extended by Berger and Moerdijk in such a way as to encompass certain similar “generalized Reedy categories” in which objects are permitted to have non-identity automorphisms [10]. Our presentation follows [102].

C.4.1. Definition. A Reedy structure on a small category $\mathcal{A}$ consists of a degree function\footnote{The degree function can take values in a different ordinal with no substantial effect on the mathematics.} $\deg : \text{obj } \mathcal{A} \rightarrow \omega$

together with a pair of wide subcategories $\mathcal{A}^-$ and $\mathcal{A}^+$ of degree-increasing and degree-decreasing arrows respectively so that

(i) For each non-identity morphism in $\mathcal{A}^-$, the degree of its domain is strictly less than the degree of its codomain, and for each non-identity morphism in $\mathcal{A}^+$, the degree of its domain is strictly greater than the degree of its domain.

(ii) Every morphism $f$ in $\mathcal{A}$ may be uniquely factored as

$$
\begin{array}{ccc}
\bullet & \overset{f}{\rightarrow} & \bullet \\
\mathcal{A}^f & \searrow & \swarrow f_{\in \mathcal{A}^+} \\
\end{array}
$$

(C.4.2)

Axiom (i) implies that $\mathcal{A}^- \cap \mathcal{A}^+ = \text{obj}(\mathcal{A})$, while both conditions together imply that $\mathcal{A}$ contains no non-identity automorphisms; see Exercise C.4.i.

C.4.3. Example. Any inverse category $\mathcal{I}$ as in Definition C.1.16 is a Reedy category, with $\mathcal{I}^- = \mathcal{I}$ and $\mathcal{I}^+ = \text{obj } \mathcal{I}$. Conversely, any Reedy category $\mathcal{A}$ with $\mathcal{A}^- = \mathcal{A}^+$ is an inverse category.

C.4.4. Example. The category $\Delta^+$ is a Reedy categories with $\Delta^+$ the monomorphisms and $\Delta^+$ the epimorphisms. Here it is convenient to take advantage of the order isomorphism $\mathbb{1} + \omega \cong \omega$ to define $\deg[n] := n$. The subcategories $\Delta$, $\Delta^+$ and $\Delta^+$ all inherit analogous Reedy category structures.

C.4.5. Remark. If $\mathcal{A}$ is a Reedy category, then so is $\mathcal{A}^{op}$: its Reedy structure has the same degree function but has the degree-increasing and degree-decreasing arrows interchanged. In particular, the Reedy categories of Example C.4.3 dualize to define direct categories, with an identity-reflecting functor $\deg : \mathcal{A} \rightarrow \omega$.

C.4.6. Remark. If $\mathcal{A}$ and $\mathcal{B}$ are Reedy categories, so is $\mathcal{A} \times \mathcal{B}$, with $\deg(a, b) := \deg(a) + \deg(b)$. See Exercise C.4.ii.

We refer to the unique factorization (C.4.2) as the Reedy factorization of the map $f$ and the degree of the object $\text{cod } \overline{f} = \text{dom } \overline{f}$ as the degree of $f$. Our next aim is to show that:

(i) The degree of $f$ is the minimal degree of an object through which $f$ factors.

(ii) The only factorization of $f$ through an object with this degree is the Reedy factorization.

To prove these assertions, consider the category $\text{Fact } f := \text{Obj } (\mathcal{A})_f \cong f(\mathcal{A})_b$ whose objects are factorizations $a \rightarrow g \rightarrow c \rightarrow h \rightarrow b$ of $f$ and whose morphisms $h \cdot g \rightarrow h' \cdot g'$ are maps $k : c \rightarrow c'$ so that the
triangles

\[ \begin{array}{ccc}
  & c & \\
 a & & h \\
 & b & \\
 g' & & g \\
 & c' & \\
 h' & & k \\
\end{array} \]

commute. Write \( \text{Fact}_{\leq n} f \subset \text{Fact} f \) for the subcategory of factorizations through an object of degree at most \( n \).

C.4.7. Lemma. The category \( \text{Fact} f \) is connected, and each subcategory \( \text{Fact}_{\leq n} f \) is either empty or connected. The minimal \( n \) with \( \text{Fact}_{\leq n} f \) non-empty is the degree of \( f \), and \( \text{Fact}_{\leq \text{deg}(f)} f \cong 1 \).

**Proof.** Consider \( h \cdot g \in \text{Fact} f \) and their Reedy factorizations:

\[
\begin{array}{ccc}
  & \bullet & \\
  & g & \\
  & \overleftarrow{g} & \overrightarrow{h} \\
  & \overleftarrow{h} & \\
  & k=\overleftarrow{h} \cdot \overrightarrow{g} & \\
  & \overleftarrow{k} & \\
\end{array}
\]

\[ (C.4.8) \]

In this way, we define a zig-zag of morphisms in \( \text{Fact} f \) connecting \( h \cdot g \) to \( \overleftarrow{hk} \cdot \overrightarrow{kg} \), which by axiom (ii) must be the Reedy factorization. This shows that \( \text{Fact} f \) is connected.

Moreover, axiom (i) implies that the degree of \( \text{cod}(g) = \text{dom}(h) \) is at least the degree of \( f \). In particular, if \( h \cdot g \in \text{Fact}_{\leq n} f \), then each of the factorizations in (C.4.8) is as well, proving that \( \text{Fact}_{\leq n} f \) is connected if it is non-empty. This diagram also shows that each non-empty category \( \text{Fact}_{\leq n} f \) contains the Reedy factorization. Hence, the minimal such \( n \) is the degree of \( f \).

Finally, if the degree of \( \text{cod}(g) = \text{dom}(h) \) equals the degree of \( f \), then \( \overleftarrow{g} \) and \( \overrightarrow{h} \) (and \( \overleftarrow{k} \) and \( \overrightarrow{k} \)) must be identities, from which we deduce that \( g \in \overrightarrow{A} \) and \( h \in \overleftarrow{A} \); i.e., that \( h \cdot g \) is the Reedy factorization.

Hence \( \text{Fact}_{\leq \text{deg}(f)} f \cong 1 \) is the terminal category as claimed.

Lemma C.4.7 will be used to establish a “cellular decomposition” for the hom bifunctor, elsewhere denoted by \( \mathcal{A}(-,-) \) but here abbreviated by \( \mathcal{A} \in \text{Set}^{\overrightarrow{A} \times \overleftarrow{A}} \). That is, we shall use the Reedy structure to present the bifunctor \( \mathcal{A} \) as a cell complex in the sense of Definition C.2.4: a sequential composite of pushouts of coproducts of basic “cells” that have a particular form. Lemma C.4.7 implies that the subset of arrows of degree at most \( n \) assembles into a subfunctor of the hom-bifunctor.

C.4.9. Definition \((n\text{-skeleton of the hom bifunctor})\). For any Reedy category \( \mathcal{A} \), the \( n \)-skeleton is the subfunctor

\[ \text{sk}_n \mathcal{A} \hookrightarrow \mathcal{A} \in \text{Set}^{\overrightarrow{A} \times \overleftarrow{A}} \]

of arrows of degree at most \( n \).

There are obvious inclusions \( \text{sk}_{n-1} \mathcal{A} \hookrightarrow \text{sk}_n \mathcal{A} \). The colimit of the sequence

\[ \emptyset \hookrightarrow \text{sk}_0 \mathcal{A} \hookrightarrow \ldots \hookrightarrow \text{sk}_{n-1} \mathcal{A} \hookrightarrow \text{sk}_n \mathcal{A} \hookrightarrow \ldots \hookrightarrow \text{colim} \text{sk}_n \mathcal{A} \cong \mathcal{A} \]
is the hom bifunctor \( \mathcal{A} \). The morphisms of degree \( n \) first appear in \( \sk_n \mathcal{A} \). It remains to express each inclusion \( \sk_{n-1} \mathcal{A} \hookrightarrow \sk_n \mathcal{A} \) as a pushout of a coproduct of basic “cells” which our next task is to describe.

The external (pointwise) product defines a bifunctor \( \mathcal{S}_{\text{Set}} \times \mathcal{S}_{\text{Set}}^\text{op} \to \mathcal{S}_{\text{Set}}^\text{op} \). For any \( a \in \mathcal{A} \), there is a natural “composition” map \( \circ : \mathcal{A}_a \square \mathcal{A}_a \to \mathcal{A} \) whose domain is the external product of the contravariant \( \mathcal{A}_a \) and covariant \( \mathcal{A}_a \) representables; here we write \( \mathcal{A}_a \) to abbreviate \( \mathcal{A}(\cdot, a) \) and \( \mathcal{A}_a \) to abbreviate \( \mathcal{A}(a, \cdot) \). By Lemma C.4.7, the composite of any pair of maps that factor through an object \( a \) of degree \( n \) lies in \( \sk_n \mathcal{A} \). Our next task is to describe the subfunctor of the domain of the map

\[
\prod_{\deg(a) = n} \mathcal{A}_a \square \mathcal{A}_a \to \sk_n \mathcal{A}
\]

that factors through \( \sk_{n-1} \mathcal{A} \hookrightarrow \sk_n \mathcal{A} \), for which we require some new notation.

C.4.10. Definition (boundaries of representable functors). If \( a \in \mathcal{A} \) has degree \( n \), write

\[
\partial \mathcal{A}_a := \sk_{n-1} \mathcal{A}_a \quad \quad \text{and} \quad \quad \partial \mathcal{A}^a := \sk_{n-1} \mathcal{A}^a.
\]

By Lemma C.4.7, \( \partial \mathcal{A}_a \hookrightarrow \mathcal{A}_a \) is the subfunctor of arrows in \( \mathcal{A} \) with domain \( a \) that do not lie in \( \overline{\mathcal{A}} \), while \( \partial \mathcal{A}^a \hookrightarrow \mathcal{A}^a \) is the subfunctor of arrows with codomain \( a \) that do not lie in \( \overline{\mathcal{A}} \).

In particular, the exterior Leibniz product

\[
\mathcal{A}_a \square \partial \mathcal{A}^a \cup \partial \mathcal{A}_a \square \mathcal{A}^a \quad \quad \text{and} \quad \quad \mathcal{A}_a \square \overline{\mathcal{A}}^a \to \overline{\mathcal{A}}_a \square \overline{\mathcal{A}}^a \quad \quad \text{(C.4.11)}
\]

defines the subfunctor of pairs of morphisms \( h \cdot g \) with \( \text{dom} h = \text{cod} g = a \) in which at least one of the morphisms \( g \) and \( h \) has degree less than the degree of \( a \).

C.4.12. Proposition. The square

\[
\prod_{\deg(a) = n} \partial \mathcal{A}_a \square \mathcal{A}^a \cup \partial \mathcal{A}_a \square \mathcal{A}^a \quad \quad \text{and} \quad \quad \mathcal{A}_a \square \overline{\mathcal{A}}^a \to \overline{\mathcal{A}}_a \square \overline{\mathcal{A}}^a \quad \quad \text{(C.4.13)}
\]

is both a pullback and a pushout in \( \mathcal{S}_{\text{Set}}^\text{op} \times \mathcal{A} \).

The fact that (C.4.13) is a pullback is used to facilitate the proof that it is also a pushout.

Proof. An element of the pullback consists of \( f \in \sk_{n-1} \mathcal{A} \) together with a factorization \( f = h \cdot g \) through an object \( a \) of degree \( n \). If both \( h \) and \( g \) have degree \( n \), then Lemma C.4.7 tells us that \( h \cdot g \) is a Reedy factorization, contradicting the fact that \( f \) has degree at most \( n - 1 \). So we must have either \( h \in \partial \mathcal{A}_a \) or \( g \in \partial \mathcal{A}^a \), which tells us that the map from the upper left corner of (C.4.13) surjects onto the pullback. Because the top-horizontal map is monic, the comparison is therefore an isomorphism; i.e., (C.4.13) is a pullback square.

To see that it is a pushout, it suffices now to show that the right-hand vertical is one-to-one on the complement of \( \sk_{n-1} \mathcal{A} \hookrightarrow \sk_n \mathcal{A} \). This follows from Lemma C.4.7, which argued that any
morphism of degree $n$ has a unique factorization through an object of that degree: namely its Reedy factorization.

As a corollary of Proposition C.4.12, the two-sided representable $𝒜$ has a canonical presentation as a cell complex.

C.4.14. THEOREM. The inclusion $∅ \hookrightarrow 𝒜$ has a canonical presentation as a cell complex:

$$\coprod_{\deg(a)=n} \partial 𝒜_a \square 𝒜^a \cup 𝒜_a \square \partial 𝒜^a \hookrightarrow \coprod_{\deg(a)=n} 𝒜_a \square 𝒜^a$$

$$∅ \hookrightarrow \sk_0 𝒜 \longrightarrow \sk_n 𝒜 \longrightarrow \colim sk_n 𝒜 \cong 𝒜$$

i.e., a composite of pushouts of coproducts of cells defined as exterior Leibniz products

$$(\partial 𝒜_a \hookrightarrow 𝒜_a) \square (\partial 𝒜^a \hookrightarrow 𝒜^a),$$

where the cell for each $a \in 𝒜$ of degree $n$ is attached at stage $n$. □

C.4.15. REMARK. One meaning of “canonical” should be “functorial.” Indeed, a morphism of Reedy categories—a functor preserving degree and the subcategories of degree-increasing and degree-decreasing maps—induces a morphism of cell complexes: given a morphism $𝒜 \to 𝒜'$ of Reedy categories, there is a natural transformation in $\Set^{𝒜op \times 𝒜}$ between the cell complex presentation for $𝒜$ and the restriction of the cell complex presentation for $𝒜'$. □

As a corollary of Theorem C.4.14, any morphism $f \in ℳ𝒜$ is itself a cell complex: the cellular decomposition of $𝒜$ is translated into a cellular decomposition for $f$ by taking weighted colimits. Taking weighted limits instead transforms the cellular decomposition of $𝒜$ into a “Postnikov presentation” for $f$ as the limit of a countable tower of pullbacks of products of particular maps. This sort of result is exemplary of the slogan of [102] that “it’s all in the weights.” Before proving this corollary, let us introduce notation for the maps appearing as the cells.

C.4.16. DEFINITION (latching and matching objects). Let $a \in 𝒜$. The **latching** and **matching objects** of diagram $X \in ℳ𝒜$ at $a$ are defined to be the colimits and limits, respectively, weighted by the boundary representables of appropriate variance:

$$L^a X := \colim{\partial 𝒜^a} X \quad M^a X := \lim{\partial 𝒜_a} X.$$  

The boundary inclusions $\partial 𝒜^a \hookrightarrow 𝒜^a$ and $\partial 𝒜_a \hookrightarrow 𝒜_a$ induce the **latching** and **matching maps** $L^a X \to X^a$ and $X^a \to M^a X$, on account of the isomorphisms $\colim{\partial 𝒜^a} X \cong X^a \cong \lim{\partial 𝒜_a} X$ of Definition A.6.1(i).

C.4.17. DEFINITION (relative latching and matching maps). The **relative latching** and **relative matching maps** of a natural transformation $f : X \to Y \in ℳ𝒜$ are defined to be the Leibniz weighted colimits and limits

$$\hat{L}^a f := \colim{\partial 𝒜^a \to 𝒜^a} f \quad \hat{M}^a f := \lim{\partial 𝒜_a \to 𝒜_a} f,$$
i.e., by the pullbacks and pushouts:

\[
\begin{array}{ccc}
L^a X & \rightarrow & X^a \\
\downarrow^{L^a f} & \searrow \downarrow & \searrow \downarrow^{f^a} \\
L^a Y & \rightarrow & e^a f & \rightarrow & \ell^a f \\
\end{array}
\]

of the maps \(L^a f := \text{colim}_{\partial \mathcal{A}} f\) and \(M^a f := \text{lim}_{\partial \mathcal{A}} f\).

C.4.18. Notation. For any diagram \(X \in \mathcal{M}^\mathcal{A}\) let

\[
\text{sk}_n X := \text{colim}_{\text{sk}_n \mathcal{A}} X \quad \text{and} \quad \text{cosk}_n X := \text{lim}_{\text{sk}_n \mathcal{A}} X
\]
denote the results of applying the weighted colimit and weighted limit bifunctors

\[
\text{colim}^- : \text{Set}^{\mathcal{A}^{op} \times \mathcal{A} \times \mathcal{M}^\mathcal{A}} \rightarrow \mathcal{M}^\mathcal{A}
\quad \text{and} \quad
\text{lim}^- : (\text{Set}^{\mathcal{A}^{op} \times \mathcal{A}})^{op} \times \mathcal{M}^\mathcal{A} \rightarrow \mathcal{M}^\mathcal{A}
\]
of Exercise A.6.iv to the diagram \(X\) with weight \(\text{sk}_n \mathcal{A}\).

C.4.19. Corollary. Let \(\mathcal{A}\) be a Reedy category and let \(\mathcal{M}\) be bicomplete. Any morphism \(f : X \rightarrow Y \in \mathcal{M}^\mathcal{A}\) is a cell complex

\[
X \rightarrow X \cup_{\text{sk}_0 X} X \rightarrow \cdots \rightarrow X \cup_{\text{sk}_{n-1} X} \text{sk}_{n-1} Y \rightarrow X \cup_{\text{sk}_n X} \text{sk}_n Y \rightarrow \cdots \rightarrow \text{colim} \cong Y
\]

with the cells

\[
(\partial \mathcal{A}_n \hookrightarrow \mathcal{A}_n) \mapsto \ell^a f
\]

indexed by objects \(a\) of degree \(n\) attached at stage \(n\), and also a “Postnikov tower”

\[
X \cong \text{lim} \rightarrow \cdots \rightarrow \text{cosk}_n X \times_{\text{cosk}_n Y} Y \rightarrow \text{cosk}_{n-1} X \times_{\text{cosk}_{n-1} Y} Y \rightarrow \cdots \rightarrow \text{cosk}_0 X \times_{\text{cosk}_0 Y} Y
\]

whose \(n\)-th layer is the product of the maps

\[
\{\partial \mathcal{A}_n \hookrightarrow \mathcal{A}_n, \ell^a f\}
\]

indexed by the objects \(a\) of degree \(n\).

Proof. These dual results follow immediately by applying the weighted colimit and weighted limit bifunctors

\[
\text{colim}^- : \text{Set}^{\mathcal{A}^{op} \times \mathcal{A} \times \mathcal{M}^\mathcal{A}} \rightarrow \mathcal{M}^\mathcal{A}
\quad \text{and} \quad
\text{lim}^- : (\text{Set}^{\mathcal{A}^{op} \times \mathcal{A}})^{op} \times \mathcal{M}^\mathcal{A} \rightarrow \mathcal{M}^\mathcal{A}
\]
to the cell complex presentations of Theorem C.4.14; recall from Definition A.6.1(ii) that both bifunctors are cocontinuous in the weight.

To see that the cell complex presentation for \(f\) has the asserted form, note that for any diagram \(X \in \mathcal{M}^\mathcal{A}\) and weight defined by an exterior product of \(U \in \text{Set}^\mathcal{A}\) and \(V \in \text{Set}^{\mathcal{A}^{op}}\), there is a natural isomorphism

\[
\text{colim}_{U \otimes V} X \cong U \ast \text{colim}_V X,
\]

which extends to a natural isomorphism between Leibniz products (Proposition C.2.9(i)).
By the coYoneda lemma, \( f \cong \text{colim} \mathcal{A} f \cong \text{colim}_{\mathcal{A} \in \mathcal{A}} f \). By Proposition C.2.9(vi), the Leibniz weighted colimit functor \( \text{colim} \) preserves cell structures. It follows that \( f \) admits a canonical presentation as a cell complex with cells

\[
\text{colim}(\partial \mathcal{A}_n \hookrightarrow \mathcal{A}_n) f \cong (\partial \mathcal{A}_n \hookrightarrow \mathcal{A}_n) \ast \text{colim}_{\mathcal{A} \in \mathcal{A}} f \cong (\partial \mathcal{A}_n \hookrightarrow \mathcal{A}_n) \ast \ell^0 f.
\]

This presentation is most familiar for the Reedy category \( \Delta^\text{op} \), in which case it is conventional to use subscripts to designate the contravariant indexing and superscripts for covariant indexing. Here we write \( \Delta^n \) for the standard \( n \)-simplex \( \Delta[n] \) and \( \partial \Delta^n \) for its boundary to be consistent with the notation of Definition C.4.10.

**C.4.22. Example.** A simplicial object \( Y \) taking values in any cocomplete category admits a skeletal filtration

\[
\emptyset \to \text{sk}_0 Y \to \cdots \to \text{sk}_{n-1} Y \to \text{sk}_n Y \to \cdots \to \text{colim} \text{sk}_n Y \cong Y
\]

in which the step from stage \( n - 1 \) to stage \( n \) is given by a pushout

\[
\Delta^n \ast L_n Y \cup \partial \Delta^n \ast Y_n \longrightarrow \Delta^n \ast Y_n
\]

\[
\downarrow r \downarrow
\]

\[
\text{sk}_{n-1} Y \longrightarrow \text{sk}_n Y
\]

where \( L_n Y \to Y_n \) is the object of “degenerate \( n \)-simplices.”

Considering the Yoneda embedding as a simplicial object \( \Delta \in (\mathcal{S}et^\Delta)^{\Delta^\text{op}} \), this specializes to the “canonical cell complex presentation” of the hom bifunctor of Theorem C.4.14

\[
\Delta^n \times \partial \Delta_n \cup \partial \Delta^n \times \Delta_n \longrightarrow \Delta^n \times \Delta_n
\]

\[
\emptyset \longrightarrow \cdots \longrightarrow \text{sk}_{n-1} \Delta \longrightarrow \text{sk}_n \Delta \longrightarrow \cdots \longrightarrow \Delta
\]

In summary, Corollary C.4.19 tells us that we may express a generic natural transformation between diagrams of shape \( \mathcal{A} \) as

(i) a cell complex whose cells are Leibniz tensors built from boundary inclusions of covariant representables and relative latching maps,

(ii) and dually as a Postnikov tower whose layers are Leibniz cotensors built from boundary inclusions of contravariant representables and relative matching maps.

This explains the importance of these maps to Reedy category theory, as we shall discover in the next section.

**Exercises.**

C.4.i. **Exercise.** Show that any isomorphism in a (strict) Reedy category is an identity.

C.4.ii. **Exercise.** Show that the product of two Reedy categories is a Reedy category, with the degree of an object defined to be the sum of the degrees.
C.5. The Reedy Model Structure

Our aim in this section is to explain how any weak factorization system on \( \mathcal{M} \) gives rise to a **Reedy weak factorization system** on \( \mathcal{M}^\mathcal{A} \). We then prove an inductive result that allows us to prove that the Reedy weak factorization systems associated to a model structure on \( \mathcal{M} \) define the **Reedy model structure** on \( \mathcal{M}^\mathcal{A} \). Finally, we prove that the weighted limit and weighted colimit bifunctors define Quillen bifunctors, as a consequence of a more general algebraic result, and discuss the consequences of this result for the theory of homotopy limits and homotopy colimits indexed by Reedy categories.

This work requires one preliminary: a discussion of how the skeleta and coskeleta introduced in the previous section feature in the inductive definition of Reedy-shaped diagrams. For a Reedy category \( \mathcal{A} \), write
\[
\mathcal{A}_{\leq 0} \subset \mathcal{A}_{\leq 1} \subset \cdots \subset \mathcal{A}_{\leq n-1} \subset \mathcal{A}_{\leq n} \subset \cdots \subset \mathcal{A}
\]
for the full subcategories of objects with degree at most the ordinal appearing in the subscript. These categories give us a new way to understand the skeleton and coskeleton functors introduced in Notation C.4.18.

C.5.1. Lemma. For any bicomplete category \( \mathcal{M} \), restriction and left and right Kan extension define an adjoint triple of functors
\[
\begin{array}{ccc}
\mathcal{M}^\mathcal{A} & \xrightarrow{\text{ran}_n} & \mathcal{M}^\mathcal{A}_{\leq n} \\
\downarrow & & \downarrow \\
\mathcal{M}^\mathcal{A}_{\leq n} & \xleftarrow{\text{lan}_n} & \mathcal{M}^\mathcal{A}
\end{array}
\]
with induced comonad \( \text{sk}_n := \text{lan}_n \circ \text{res}_n \) and monad \( \text{cosk}_n := \text{ran}_n \circ \text{res}_n \) naturally isomorphic to the functors defined by weighted colimit and weighted limit
\[
\text{lan}_n \text{res}_n (-) \cong \text{colim}_{\text{sk}_n \mathcal{A}} (-) \quad \text{and} \quad \text{ran}_n \text{res}_n (-) \cong \text{lim}_{\text{sk}_n \mathcal{A}} (-).
\]

**Proof.** Exercise C.5.i. \( \square \)

For example:

C.5.2. Definition. Specializing the notation above, write \( \Delta_{\leq n} \subset \Delta \) for the full subcategory of the simplex category of 1.1.1 spanned by the ordinals \([0], \ldots, [n]\). Restriction and left and right Kan extension define adjunctions
\[
\begin{array}{ccc}
\text{Set}^{\Delta^\text{op}} & \xleftarrow{\text{ran}_n} & \text{Set}^{\Delta_{\leq n}^\text{op}} \\
\downarrow & & \downarrow \\
\text{Set}^{\Delta_{\leq n}^\text{op}} & \xrightarrow{\text{lan}_n} & \text{Set}^{\Delta^\text{op}}
\end{array}
\]
inducing an idempotent comonad \( \text{sk}_n := \text{lan}_n \circ \text{res}_n \) and an idempotent monad \( \text{cosk}_n := \text{ran}_n \circ \text{res}_n \) on \( s\text{Set} \) that are adjoint \( \text{sk}_n \dashv \text{cosk}_n \). The counit and unit of this comonad and monad define canonical maps
\[
\text{sk}_n X \xleftarrow{\epsilon} X \xrightarrow{\eta} \text{cosk}_n X
\]
relating a simplicial set \( X \) with its \( n \)-**skeleton** and \( n \)-**coskeleton**. We say \( X \) is \( n \)-**skeletal** or \( n \)-**coskeletal** if the former or latter of these maps, respectively, is an isomorphism.

The following lemma records special properties of an adjoint triple of functors \( \text{lan}_n \dashv \text{res}_n \dashv \text{ran}_n \) arising from a fully-faithful inclusion \( \text{sk}_n \mathcal{A} \hookrightarrow \mathcal{A} \). In particular, the canonical map from the \( n \)-**skeleton**
of a simplicial set to its $n$-coskeleton can be defined more generally, not just for diagrams defined as restrictions:

C.5.3. Lemma. For any fully faithful inclusion $ℬ → ℬ$ and bicomplete category $ℳ$, consider the associated adjoint triple:

\[
\begin{array}{ccc}
ℳ^ℬ & \xleftarrow{\text{lan}} & ℳ^ℬ \\
\downarrow & \searrow & \downarrow \\
ℳ^𝒜 & \xleftarrow{\text{res}} & ℳ^ℬ \\
\downarrow & \nearrow & \downarrow \\
ℳ^ℬ & \xrightarrow{\text{ran}} & ℳ^ℬ
\end{array}
\]

(i) The functors $\text{lan}, \text{ran}: ℳ^ℬ → ℳ^ℬ$ are fully faithful; that is, the unit of $\text{lan} → \text{res}$ and the counit of $\text{res} → \text{ran}$ are isomorphisms.

(ii) The common composite in the commutative square below defines a canonical natural transformation

\[
\begin{array}{cccc}
\text{lan} & \xrightarrow{\eta \text{lan}} & \text{ran} & \text{lan res lan} \\
\text{lan res ran} & \xrightarrow{\varepsilon \text{ran}} & \text{ran}
\end{array}
\]

While we find the commutative square in (ii) amusing, since the inclusion $ℬ → ℬ$ is fully faithful, that $\tau$ can be defined more simply using the universal properties of left and right Kan extensions as the initial and terminal functors that extend a given diagram.

Proof. It is well-known that a right adjoint functor is fully faithful if and only if the counit is an isomorphism and that the counit of a pointwise right Kan extension along a fully faithful functor is an isomorphism; for proofs, specialize the results of Lemma 9.4.4 and Proposition 9.4.5 to the $\infty$-cosmos $\mathbf{Cat}$. These statements and their duals prove (i).

In (ii), $\tau$ is defined to be the adjoint transpose of $\eta^{-1}: \text{res lan} \Rightarrow \text{id}$ under $\text{res} → \text{ran}$ and also to be the adjoint transpose of $\varepsilon^{-1}: \text{id} \Rightarrow \text{res ran}$ under $\text{lan} → \text{res}$. To see that these definitions agree, observe that the former asserts that the composite of the right two morphisms below is the unique right inverse of the left morphism, while the latter asserts that the composite of the left two morphisms below is the unique left inverse of the right morphism:

\[
\begin{array}{cccc}
\text{id} & \xrightarrow{\eta} & \text{res lan} & \xrightarrow{\tau} \text{res ran} & \xrightarrow{\varepsilon} \text{id}
\end{array}
\]

In other words, both definitions assert exactly that the displayed triple composite is the identity. □

In this way, we obtain a natural transformation $\tau_n: \text{sk}_n \Rightarrow \text{cosk}_n$ between the comonad and monad introduced in Lemma C.5.1. These structures allow us to inductively define Reedy diagrams:

C.5.4. Proposition (inductive definition of diagrams).

(i) A diagram $X ∈ ℳ^{𝒜_{≤n−1}}$ together with a family of factorizations

\[
\begin{array}{ccc}
\text{sk}_{n−1} X^a & \xrightarrow{\tau_{n−1} X^a} & \text{cosk}_{n−1} X^a \\
\downarrow & \nearrow & \downarrow \\
X^a & \xleftarrow{p} & X^a
\end{array}
\]

for each object $a ∈ 𝒜$ of degree $n$ uniquely determines a diagram $X ∈ ℳ^{𝒜_{≤n}}$ whose restriction to degree $n − 1$ coincides with the original diagram.
(ii) A natural transformation \( f : X \to Y \in \mathcal{M}^{\mathcal{A}_{\leq n-1}} \) together with a family of factorizations

\[
\begin{align*}
\tau_{n-1}X^a & \quad \xrightarrow{\rho^a} \quad X^a & \quad \xrightarrow{\cosk_{n-1}X^a} \\
sk_{n-1}X^a & \quad \xrightarrow{f^a} \quad Y^a & \quad \xrightarrow{\cosk_{n-1}Y^a} \\
sk_{n-1}Y^a & \quad \xrightarrow{p^a} \quad Y^a
\end{align*}
\]

for each object \( a \in \mathcal{A} \) of degree \( n \) uniquely determines a natural transformation \( f : X \to Y \in \mathcal{M}^{\mathcal{A}_{\leq n}} \) whose restriction to degree \( n \) coincides with the original natural transformation.

**Proof.** For (i), it remains to define the action of \( \mathcal{X} \) on non-identity morphisms whose domain or codomain has degree \( n \). The Reedy factorization of any such morphism \( k : a \to a' \) is through an object \( b \) of degree less than \( n \). By composing the maps in the upper-right or lower-left square, there exist unique dotted-arrow maps making the following diagram commute

\[
\begin{align*}
\tau_{n-1}X^a & \quad \xrightarrow{\rho^a} \quad X^a & \quad \xrightarrow{\cosk_{n-1}X^a} \\
sk_{n-1}X^a & \quad \xrightarrow{p^a} \quad X^b & \quad \xrightarrow{\cosk_{n-1}X^b} \\
sk_{n-1}X^b & \quad \xrightarrow{\rho^b} \quad X^b & \quad \xrightarrow{\cosk_{n-1}X^b} \\
sk_{n-1}X^b & \quad \xrightarrow{p^b} \quad X^a & \quad \xrightarrow{\cosk_{n-1}X^a} \\
sk_{n-1}X^a & \quad \xrightarrow{p^a} \quad X^{a'} & \quad \xrightarrow{\cosk_{n-1}X^{a'}} \\
sk_{n-1}X^{a'} & \quad \xrightarrow{p^{a'}} \quad X^{a'} & \quad \xrightarrow{\cosk_{n-1}X^{a'}}
\end{align*}
\]

The functoriality of this construction in a pair of composable maps \( (h, k) \) follows from connectedness of the category \( \mathcal{F}act_{\leq n-1}(hk) \).

For (ii), apply (i) to the diagram \( a \mapsto f^a : \mathcal{A}_{\leq n-1} \to M^2 \). □

Now we turn our attention to the main subject of this section. Let \( \mathcal{M} \) be a category with a weak factorization system \( (\mathcal{L}, \mathcal{R}) \) and let \( \mathcal{A} \) be a Reedy category.

**C.5.5. Definition.** The **Reedy weak factorization system** \( (\mathcal{L}[\mathcal{A}], \mathcal{R}[\mathcal{A}]) \) on \( \mathcal{M}^{\mathcal{A}} \) defined relative to the weak factorization system \( (\mathcal{L}, \mathcal{R}) \) on \( \mathcal{M} \) has:

- as left class \( \mathcal{L}[\mathcal{A}] \) those maps \( f : X \to Y \in \mathcal{M}^{\mathcal{A}} \) whose relative latching maps \( \ell^a f : \ell^a f \to Y^a \in \mathcal{M} \) are in \( \mathcal{L} \), and
- as right class \( \mathcal{R}[\mathcal{A}] \) those maps \( f : X \to Y \in \mathcal{M}^{\mathcal{A}} \) whose relative matching maps \( m^a f : X^a \to m^a f \in \mathcal{M} \) are in \( \mathcal{R} \).

We say a map \( f : X \to Y \in \mathcal{M}^{\mathcal{A}} \) is **Reedy in** \( \mathcal{L} \) or **Reedy in** \( \mathcal{R} \) if its relative latching or relative matching maps are in \( \mathcal{L} \) or \( \mathcal{R} \), respectively.

The classes \( \mathcal{L}[\mathcal{A}] \) and \( \mathcal{R}[\mathcal{A}] \) are lifts, respectively, of the classes \( \mathcal{L} \) and \( \mathcal{R} \) along the \( \mathcal{A} \)-indexed family of functors \( \ell^a : (\mathcal{M}^{\mathcal{A}})^2 \to \mathcal{M}^2 \) or \( m^a : (\mathcal{M}^{\mathcal{A}})^2 \to \mathcal{M}^2 \). By functoriality, we see that these classes are closed under retracts. Now Exercise C.2.ii combines with the following pair of lemmas to imply that these two classes indeed define a weak factorization system on the category \( \mathcal{M}^{\mathcal{A}} \).
C.5.6. Lemma. The maps $i \in \mathcal{L}[\mathcal{A}]$ have the left lifting property with respect to the maps $p \in \mathcal{R}[\mathcal{A}]$.

\[
\begin{array}{c}
A 
\xrightarrow{\ i \ } 
K \\
\downarrow 
\ddashrightarrow 
\downarrow \\
B
\xrightarrow{\ p \ } 
L
\end{array}
\]

Proof. By Corollary C.4.19, to show that $i \sqcup p$ for any pair of morphisms $i, p \in \mathcal{M}[\mathcal{A}]$, it suffices to solve the lifting problems below-left

\[
\begin{array}{ccc}
\bullet & \xrightarrow{\ i \ } & \bullet \\
\downarrow & \xrightarrow{\ p \ } & \downarrow \\
\bullet & \xrightarrow{\ \ell \ } & \bullet
\end{array}
\quad
\begin{array}{ccc}
\bullet & \xrightarrow{\ \ell \ } & \bullet \\
\downarrow & \xrightarrow{\ \ell \ } & \downarrow \\
\bullet & \xrightarrow{\ \ell m_{\partial} \ell \ } & \bullet
\end{array}
\]

in $\mathcal{M}[\mathcal{A}]$ for each $a \in \mathcal{A}$. By adjunction, it suffices to solve the transposed lifting problem in $\mathcal{M}$ above-right. If $i \in \mathcal{L}[\mathcal{A}]$ and $p \in \mathcal{R}[\mathcal{A}]$, then by definition $\ell^a i \in \mathcal{L}$ and $\ell m^a p \in \mathcal{R}$, so a solution exists. \hfill $\square$

C.5.7. Lemma. Every map $f \colon X \rightarrow Y \in \mathcal{M}[\mathcal{A}]$ can be factored as a map in $\mathcal{L}[\mathcal{A}]$ followed by a map in $\mathcal{R}[\mathcal{A}]$.

Proof. We define the components of the factorization of $f^a \colon X^a \rightarrow Y^a$ inductively in the degree of $a$. To start, we use the factorization of $(\mathcal{L}, \mathcal{R})$ to factor all components indexed by objects at degree zero. Since the full subcategory $\mathcal{A}_{\leq 0}$ spanned by these objects is discrete, this defines a factorization of the subdiagram $f \in \mathcal{M}^{\mathcal{A}_{\leq 0}}$.

Continuing inductively, suppose we have factored the restriction $f \in \mathcal{M}^{\mathcal{A}_{\leq n}}$ as

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & \xrightarrow{\ell} & \downarrow \\
Z
\end{array}
\]

with the relative latching maps $\ell^a \ell \in \mathcal{L}$ and $\ell^a r \in \mathcal{R}$ for all objects $a$ of degree less than $n$. By Proposition C.5.4, to define the attendant factorization of $f^a$, it suffices to define an object $Z^a$ of $\mathcal{M}$ together with the dotted arrow maps
We factor the diagonal map from the pushout to the pullback using \((\mathcal{L}, \mathcal{R})\) to define the object \(Z^a\). The left and right factors become the \(a\)-th relative latching map and matching map of the composite morphisms \(\ell^a\) and \(r^a\) so-defined. Note by construction that these maps lie in the classes \(\mathcal{L}\) and \(\mathcal{R}\), respectively. It follows from the universal properties of the pushout and the pullback that \(f^a = r^a \cdot \ell^a\). By Proposition C.5.4 these definitions extend the natural transformations \(\ell\) and \(r\) to degree \(n\).

It follows from Corollary C.4.19 that if the left class of a weak factorization system \((\mathcal{L}, \mathcal{R})\) on \(\mathcal{M}\) is cofibrantly or cellularly generated, as in Definition C.2.4, then the left class of the Reedy weak factorization system is too:

C.5.8. **Proposition.** If \((\mathcal{L}, \mathcal{R})\) is a weak factorization system on \(\mathcal{M}\) that is cellularly or cofibrantly generated by the class of maps \(\mathcal{J}\), then the Reedy weak factorization system \((\mathcal{L}[\mathcal{A}], \mathcal{R}[\mathcal{A}])\) on \(\mathcal{M}[\mathcal{A}]\) is cellularly or cofibrantly generated, respectively, by the class

\[
\{(\partial A_a \hookrightarrow A_a) \ast j \}_{a \in A, j \in \mathcal{J}}.
\]

**Proof.** By Corollary C.4.19, any morphism \(f: X \to Y \in \mathcal{M}[\mathcal{A}]\) may be presented as a cell complex built from cells

\[
\{(\partial A_a \hookrightarrow A_a) \ast \tilde{\ell}^a f \}_{a \in \mathcal{A}}.
\]

If \(f \in \mathcal{L}[\mathcal{A}],\) then \(\tilde{\ell}^a f \in \mathcal{L}\) for each \(a\), and by hypothesis these relative latching maps may be presented as cell complexes or retracts of cell complexes built from the maps in the generating class \(\mathcal{J}\). By Proposition C.2.9(vi), the Leibniz tensors \((\partial A_a \hookrightarrow A_a) \ast \tilde{\ell}^a f\) may then be presented as (retracts of) cell complexes built from the Leibniz tensors of the boundary inclusions and the maps in \(\mathcal{J}\), exactly as claimed in the statement. □

For example, the monomorphisms of simplicial sets are cellularly generated by the simplex boundary inclusions \((\partial \Delta[n] \hookrightarrow \Delta[n])\) for \(n \geq 0\).

C.5.9. **Lemma.** The Reedy weak factorization system \((\text{mono}[\Delta^{op}], \text{epi}[\Delta^{op}])\) on \(s\text{Set} = \text{Set}^{\Delta^{op}}\) defined relative to the (monomorphism, epimorphism) weak factorization system on \(\text{Set}\) coincides with the (monomorphism, trivial fibration) weak factorization system. Consequently, any monomorphism of simplicial sets decomposes canonically as a sequential composite of pushouts of coproducts of the maps \(\partial \Delta[n] \hookrightarrow \Delta[n]\) for \(n \geq 0\).

**Proof.** Monomorphisms of sets are cellularly generated by a single map, the inclusion \(!: \emptyset \hookrightarrow *\). Consequently, by Proposition C.5.8, the Reedy weak factorization system is cellularly generated as well. In this case, the pushout product functor \(- \ast !: \text{Set}^{\Delta^{op}} \to \text{Set}^{\Delta^{op}}\) is the identity, so the set of generating maps are the familiar simplex boundary inclusions \(\{\partial \Delta[n] \hookrightarrow \Delta[n]\}_{n \in \Delta}\), the right lifting property against which is used in Definition 1.1.24 to characterize the trivial fibrations. □

C.5.10. **Proposition.**

(i) If \(f: X \to Y \in \mathcal{M}[\mathcal{A}]\) is Reedy in \(\mathcal{L}\), that is, if the relative latching maps \(\tilde{\ell}^a f\) are in \(\mathcal{L}\), then each of the components \(f^a: X^a \to Y^a\) and each of the latching maps \(L^a f: L^a X \to L^a Y\) are also in \(\mathcal{L}\).

(ii) If \(f: X \to Y \in \mathcal{M}[\mathcal{A}]\) is Reedy in \(\mathcal{R}\), that is, if the relative matching maps \(\tilde{m}^a f\) are in \(\mathcal{L}\), then each of the components \(f^a: X^a \to Y^a\) and each of the matching maps \(M^a f: M^a X \to M^a Y\) are also in \(\mathcal{R}\).

**Proof.** We prove the first of these dual statements. The maps \(f^a\) and \(L^a f\) are the Leibniz weighted colimits of \(f\) with the maps \(\emptyset \hookrightarrow \mathcal{A}^a\) and \(\emptyset \hookrightarrow \partial \mathcal{A}^a\) respectively. Evaluating the covariant variable
of the cell complex presentation of Theorem C.4.14 at \( a \in \mathcal{A} \), we see that \( \emptyset \hookrightarrow \mathcal{A} \) is a cell complex whose cells have the form
\[
((\partial \mathcal{A}_x)^a \hookrightarrow \mathcal{A}_x^a) \sqcup (\partial \mathcal{A}_x \hookrightarrow \mathcal{A}_x) \tag{C.5.11}
\]
indexed by the objects \( x \in \mathcal{A} \). In fact, it suffices to consider those objects with \( \deg(x) \leq \deg(a) \); when \( \deg(x) > \deg(a) \), the inclusion \( (\partial \mathcal{A}_x)^a \hookrightarrow \mathcal{A}_x^a \), and hence the cell \( (C.5.11) \), is an isomorphism. Similarly, since \( \partial \mathcal{A}_a = \text{sk}_{\deg(a)-1} \mathcal{A}_a \), Theorem C.4.14 implies that \( \emptyset \hookrightarrow \partial \mathcal{A}_a \) is a cell complex whose cells have the form \( (C.5.11) \) with \( \deg(x) < \deg(a) \).

By Proposition C.2.9(vi), the maps \( f^a \) and \( L^a f \) are then cell complexes whose cells, indexed by the objects \( x \in \mathcal{A} \) with the degree bounds just discussed, have the form
\[
\colim_{(\partial \mathcal{A}_x)^a \hookrightarrow \mathcal{A}_x^a} f \cong ((\partial \mathcal{A}_x)^a \hookrightarrow \mathcal{A}_x^a) \ast \tilde{L}^x f, \tag{C.5.12}
\]
the isomorphism arising from Proposition C.2.9(i). By Lemma C.2.12, the Leibniz tensor of a mono-morphism with a map in the left class of a weak factorization system is again in the left class. Thus, since \( (\partial \mathcal{A}_x)^a \hookrightarrow \mathcal{A}_x^a \) is a monomorphism and \( \tilde{L}^x f \) is in \( \mathcal{L} \), these cells, and thus the maps \( f^a \) and \( L^a f \) are in \( \mathcal{L} \) as well.

Recall from Definition C.3.1 that a model structure on a category \( \mathcal{M} \) with a class of weak equivalences \( \mathcal{W} \) satisfying the 2-of-3 property is given by two classes of maps \( \mathcal{C} \) and \( \mathcal{F} \) so that \( (\mathcal{C} \cap \mathcal{W}, \mathcal{F}) \) and \( (\mathcal{C}, \mathcal{F} \cap \mathcal{W}) \) define weak factorization systems. To show that the Reedy weak factorization systems on \( \mathcal{M}^\mathcal{A} \) relative to a model structure on \( \mathcal{M} \) define a model structure on \( \mathcal{M}^\mathcal{A} \) with the weak equivalences defined pointwise, one lemma is needed.

**C.5.13. Lemma.** Let \( (\mathcal{W}, \mathcal{C}, \mathcal{F}) \) define a model structure on \( \mathcal{M} \). Then a map \( f : X \to Y \in \mathcal{M}^\mathcal{A} \)

(i) is Reedy in \( \mathcal{C} \cap \mathcal{W} \) if and only if \( f \) is Reedy in \( \mathcal{C} \) and a pointwise weak equivalence, and

(ii) is Reedy in \( \mathcal{F} \cap \mathcal{W} \) if and only if \( f \) is Reedy in \( \mathcal{F} \) and a pointwise weak equivalence.

**Proof.** We prove the first of these dual statements. If \( f \) is Reedy in \( \mathcal{C} \cap \mathcal{W} \), then it is obviously Reedy in \( \mathcal{C} \), and Proposition C.5.10 implies that its components \( f^a \) are also in \( \mathcal{C} \cap \mathcal{W} \). Thus \( f \) is a pointwise weak equivalence.

For the converse, we make use of the diagram
\[
\begin{array}{ccc}
L^a X & \xrightarrow{L^a f} & L^a Y \\
\downarrow & & \downarrow \\
X^a & \xrightarrow{r} & Y^a \\
\end{array}
\]
which relates the maps \( L^a f, \tilde{L}^a f, \) and \( f^a \) for any \( a \in \mathcal{A} \); this is an instance of Proposition C.2.9(v) applied to \((\emptyset \hookrightarrow \partial \mathcal{A}_a \hookrightarrow \mathcal{A}_a) \ast \mathcal{A} \). Suppose that \( f \) is Reedy in \( \mathcal{C} \) and a pointwise weak equivalence. By Proposition C.5.10, it follows that \( L^a f \) is in \( \mathcal{C} \). We will show that \( L^a f \) is in fact in \( \mathcal{C} \cap \mathcal{W} \) and then apply pushout stability of the left class of a weak factorization system and the 2-of-3 property, to conclude that \( \tilde{L}^a f \in \mathcal{W} \) and hence that \( f \) is Reedy in \( \mathcal{C} \cap \mathcal{W} \). We argue by induction. If \( a \) has degree zero, then \( L^a f \) is the identity at the initial object, which is certainly a weak equivalence, and \( \tilde{L}^a f = f^a \) is in \( \mathcal{C} \cap \mathcal{W} \). If \( a \) has degree \( n \), we may now assume that \( \tilde{L}^x f \in \mathcal{C} \cap \mathcal{W} \) for any \( x \) with degree less than
the degree of $a$. By the proof of Proposition C.5.10, $L^{\alpha} f$ may be presented as a cell complex whose cells (C.5.12) are Leibniz tensors of monomorphisms with maps in $C \cap W$, and thus lie in $C \cap W$. Thus, we conclude that $L^{\alpha} f \in C \cap W$, completing the proof. □

Lemmas C.5.6, C.5.7, and C.5.13 assemble to prove:

C.5.14. **Theorem** (the Reedy model structure). If $𝒜$ is a Reedy category and $(W, C, F)$ define a model structure on $M$, then the Reedy weak factorization systems $(C \cap W[𝒜], F[𝒜])$ and $(C[𝒜], F \cap W[𝒜])$ define a model structure on $M^{𝒜}$ with pointwise weak equivalences. □

One reason for our interest in the Reedy model structure is it comes equipped with convenient Quillen bifunctors arising from the following result, which produces left Leibniz bifunctors in the sense of Definition C.2.10 in the Reedy diagram context.

C.5.15. **Theorem.** Let $𝒜$ be a Reedy category and let $⊗: V \times M \to N$ be a left Leibniz bifunctor with respect to weak factorization systems $(ℒ, ℛ)$, $(ℒ', ℛ')$, and $(ℒ'', ℛ'')$. Then the functor tensor product

$$⊗_{𝒜}: V^{\text{op}} \times M^{𝒜} \to N$$

is left Leibniz with respect to the Reedy weak factorization systems $(ℒ[𝒜^{\text{op}}], ℛ[𝒜^{\text{op}}])$ and $(ℒ'[𝒜], ℛ'[𝒜])$ and $(ℒ'', ℛ'')$.

The functor tensor product of $F \in V^{\text{op}}$ and $G \in M^{𝒜}$ is defined by the coend

$$F⊗_{𝒜} G := \int^{a \in 𝒜} \text{coeq} \left( \coprod_{a,b \in 𝒜} \coprod_{A(a,b)} F a ⊗ G b \Rightarrow \coprod_{a \in 𝒜} F a ⊗ G a \right).$$

**Proof.** As a construction built from a cocontinuous functor and colimits, the functor tensor product is cocontinuous in both variables. We argue that $⊗_{𝒜}$ has the Leibniz property. Corollary C.4.19 asserts that the maps $f \in V^{\text{op}}$ can be built as cell complexes whose cells are Leibniz products

$$(\partial A \hookrightarrow A) \hat{⊗} \ell_{a} f,$$

and the maps $g \in M^{𝒜}$ can be built as cell complexes whose cells are Leibniz products

$$(\partial A_{b} \hookrightarrow A_{b}) \hat{⊗} \ell_{b} g.$$

By Proposition C.2.9(vi), $f \hat{⊗}_{𝒜} g$ is then a cell complex whose cells have the form

$$\left((\partial A \hookrightarrow A) \hat{⊗} \ell_{a} f\right) \hat{⊗}_{𝒜} \left((\partial A_{b} \hookrightarrow A_{b}) \hat{⊗} \ell_{b} g\right) \cong \left((\partial A \hookrightarrow A) \times_{𝒜} (\partial A_{b} \hookrightarrow A_{b})\right) \hat{⊗} (\ell_{a} f \hat{⊗} \ell_{b} g).$$

To say that $f$ is Reedy in $ℒ$ and $g$ is Reedy in $ℒ'$ means that $\ell_{a} f \in ℒ$ and $\ell_{b} g \in ℒ'$. Since $⊗$ is left Leibniz, it follows that $\ell_{a} f \hat{⊗} \ell_{b} g \in ℒ'$. The Leibniz functor tensor product

$$(\partial A \hookrightarrow A) \hat{⊗}_{𝒜} (\partial A_{b} \hookrightarrow A_{b})$$

of the maps in $\text{Set}^{𝒜^{\text{op}}}$ and in $\text{Set}^{𝒜}$ amounts to the inclusion into the hom-set $A_{b} = 𝒜(b, a)$ of the subset of morphisms from $b$ to $a$ that factor through an object of degree strictly less than $a$ or strictly less than $b$; in particular, this map is a monomorphism. Now Lemma C.2.12 applies to the weak factorization system $(ℒ'', ℛ'')$ on $N$ to prove that the Leibniz tensor of this monomorphism with $\ell_{a} f \hat{⊗} \ell_{b} g$ remains in $ℒ'$, completing the proof. □
For example, by (A.6.4), the weighted colimit bifunctor is the functor tensor product defined from the set-tensor bifunctor of Lemma C.2.12. Applying Theorem C.5.15 with (monomorphism, epimorphism) taken as the default weak factorization system on Set, we conclude:

C.5.16. COROLLARY. For any bicomplete category M with a weak factorization system (L, R) and any Reedy category, the weighted colimit and weighted limit
\[
colim_-: \text{Set}^\mathcal{A} \times M^{\mathcal{A}^{op}} \to M \quad \text{and} \quad \lim_-: (\text{Set}^\mathcal{A})^{op} \times M^\mathcal{A} \to M
\]
define left and right Leibniz bifunctors relative to the Reedy weak factorization systems. □

In the setting of a model category, a cartesian closed model category, or a V-model category (which subsumes the previous two cases by taking V to be Set with the model structure of Exercise C.3.iv or taking V to be the model category itself), Corollary C.5.16 specializes to the following result, which helps us understand homotopy limits and colimits of diagrams of Reedy shape.

C.5.17. COROLLARY. Let M be a V-model category and let A be a Reedy category. Then for any weight W in V^A that is Reedy cofibrant\(^{11}\), the weighted colimit and weighted limit functors
\[
colim_W -: M^{\mathcal{A}^{op}} \to M \quad \text{and} \quad \lim_W -: M^\mathcal{A} \to M
\]
are respectively left and right Quillen with respect to the Reedy model structure on M^A.

PROOF. By Exercise C.3.iii, the Quillen bifunctors give rise to Quillen functors when plugging a cofibrant object into the appropriate variable. □

C.5.18. EXAMPLE (homotopy limits and colimits). Taking the terminal weight 1 in Set^A, the weighted limit reduces to the ordinary limit functor. The functor 1 \in Set^A is Reedy monomorphic just when, for each a \in \mathcal{A}, the category of elements for the weight \partial\mathcal{A}^a is either empty or connected. This is the case if and only if \mathcal{A} has cofibrant constants, meaning that the constant \mathcal{A}-indexed diagram at any cofibrant object in any model category is Reedy cofibrant. Thus, we conclude that if \mathcal{A} has cofibrant constants, then the limit functor \lim: M^\mathcal{A} \to M is right Quillen.

Dually, the colimit functor \colim: M^\mathcal{A} \to M is a special case of the weighted colimit functor with the terminal weight 1 \in Set^{\mathcal{A}^{op}}. This is Reedy monomorphic just when each category of elements for the weights \partial\mathcal{A}^a is either empty or connected, which is the case if and only if \mathcal{A} has fibrant constants, meaning that the constant \mathcal{A}-indexed diagram at any fibrant object in any model category is Reedy fibrant. Thus, we conclude that if \mathcal{A} has fibrant constants, then the colimit functor \colim: M^\mathcal{A} \to M is left Quillen. See [102, §9] for more discussion.

The following lemmas can be used to identify Reedy cofibrant weights for use in applications of Corollary C.5.17.

C.5.19. LEMMA. Any bisimplicial set is Reedy cofibrant as an object of sSet^{A^{op}}.

PROOF. Exercise C.5.ii. □

Reedy cofibrant cosimplicial objects can also be identified, on account of the following lemma.

C.5.20. LEMMA.\(^{11}\) In the case of V = Set, “Reedy cofibrant” should be read as “Reedy monomorphic.”
(i) Let \( X: \Delta \to \text{Set}^{\mathcal{J}_{\text{Top}}} \) be a cosimplicial object in a presheaf category. If \( X \) is unaugmentable, in the sense that the equalizer of the pair of coface maps \( \delta^0, \delta^1: X^0 \to X^1 \) is empty, then the latching maps of \( X \) are all monomorphisms.

(ii) If \( X \) is an unaugmentable cosimplicial object in a slice category of a presheaf category, then the latching maps of \( X \) are all monomorphisms.

**Proof.** Since latching objects are defined in terms of certain colimits in \( \text{Set}^{\mathcal{J}_{\text{Top}}} \) computed pointwise in \( \text{Set} \), we may reduce this result to the corresponding one for cosimplicial sets \( X: \Delta \to \text{Set} \). A simplex in a cosimplicial set is “non-degenerate” if it is not in the image of a monomorphism from \( \Delta \). The \( n \)th latching map \( L^nX \to X^n \) is a monomorphism just when each expression of an \( n \)-simplex \( x \) as the image of a non-degenerate simplex \( z \) under a monomorphism \( \sigma: [k] \to [n] \) is unique.

So suppose we have two such representations \( x = \sigma \cdot z = \sigma' \cdot z' \). Any monomorphism \( \sigma \in \Delta \) has a left inverse \( \tau \), so we see that \( z = \tau \sigma' \cdot z' \). The map \( \tau \sigma' \) can be factored as an epimorphism followed by a monomorphism. Because \( z \) is non-degenerate, this monomorphism must be the identity, so \( \tau \sigma' \) is an epimorphism. Repeating this argument with an left inverse \( \tau' \) for \( \sigma' \) we see that \( \tau' \sigma \) is an epimorphism, so \( z \) and \( z' \) have the same degree and both epimorphisms are identities. This proves that \( z = z' \).

If the set of left inverses for a monomorphism uniquely characterized that monomorphism, then we could conclude that \( \sigma \) and \( \sigma' \) must be equal, and hence that such decompositions would be fully unique. This is true for nearly all monomorphisms in \( \Delta \), the only exceptions being the face maps \( \delta^0, \delta^1: [0] \to [1] \). However, \( X \) is assumed to be unaugmentable, so there is no \( z \in Z^0 \) with \( \delta^0 z = \delta^1 z \), and thus \( L^nX \to X^n \) is a monomorphism for all \( n \). This proves the first statement.

For the second statement, we only need to consider slice categories \( \mathcal{A} \text{Set}^{\mathcal{J}_{\text{Top}}} \) under a presheaf \( A \in \mathcal{Set}^{\mathcal{J}_{\text{Top}}} \), since the slice category \( \mathcal{Set}^{\mathcal{J}_{\text{Top}}} \downarrow A \) is equivalent to the category of presheaves on the category of elements of \( A \). The forgetful functor \( \mathcal{A} \text{Set}^{\mathcal{J}_{\text{Top}}} \to \text{Set}^{\mathcal{J}_{\text{Top}}} \) creates monomorphisms and connected colimits, which tells us that the latching maps \( L^nX \to X^n \) of a complicial object \( X^\bullet \) in \( \mathcal{A} \text{Set}^{\mathcal{J}_{\text{Top}}} \) are calculated in \( \text{Set}^{\mathcal{J}_{\text{Top}}} \) for all \( n > 1 \). The direct calculation given above proves that these are monomorphisms. If \( X \) is unaugmentable, the latching map \( (\delta^0, \delta^1): L^1X \cong X^0 + X^0 \to X^1 \) is a monomorphism: arguing in \( \text{Set}^{\mathcal{J}_{\text{Top}}} \) and then ultimately in \( \text{Set} \), it is easy to see that the pullback of this map along itself is \( A \). If \( X \) is unaugmentable, this says also that the equalizer of \( (\delta^0, \delta^1): X^0 \to X^1 \) in \( \text{Set}^{\mathcal{J}_{\text{Top}}} \) is \( A \to X^0 \), so this map is a monomorphism. This tells us that the 0th latching map is a monomorphism, completing the proof that \( X^\bullet \) is a Reedy monomorphism.

**Example (geometric realization and totalization).** By Lemma C.5.20, the Yoneda embedding defines a Reedy cofibrant weight \( \Delta^\bullet \in \mathcal{sSet}^{\Delta} \). The weighted colimit and weighted limit functors

\[
\text{colim}_{\Delta^\bullet} -: \mathcal{M}^{\Delta_{\text{op}}} \to \mathcal{M} \quad \text{and} \quad \text{lim}_{\Delta^\bullet} -: \mathcal{M}^{\Delta} \to \mathcal{M}
\]

typically go by the names of **geometric realization** and **totalization**. Corollary C.5.17 proves that if \( \mathcal{M} \) is a simplicial model category, then these functors are left and right Quillen.

We frequently invoke Lemma C.5.20 in conjunction with the following result to show that various quasi-categories or Kan complexes are equivalent. The geometric idea is as follows: when \( X^\bullet \in \mathcal{M}^{\Delta} \) is a cosimplicial object in \( \mathcal{M} \), then for any object \( A \in \mathcal{M} \) we may define a simplicial set \( \mathcal{M}(X^\bullet, A) \) in which the \( n \)-simplices are maps \( X^n \to A \) in \( \mathcal{M} \). We think of the cosimplicial object \( X^\bullet \) as determining the “shape” of the simplices in \( \mathcal{M}(X^\bullet, A) \). The following lemma gives us a tool for proving that the simplicial sets constructed via different shapes are equivalent.
C.5.22. Lemma. Suppose $\mathcal{M}$ is a model category, $f^\bullet : X^\bullet \to Y^\bullet \in \mathcal{M}^\Delta$ is a map of cosimplicial objects, and $A$ is a fibrant object in $\mathcal{M}$. On applying the representable functor $\mathcal{M}(-, A) : \mathcal{M}^{\text{op}} \to \text{Set}$ we obtain a map of simplicial sets

$$\mathcal{M}(f^\bullet, A) : \mathcal{M}(Y^\bullet, A) \to \mathcal{M}(X^\bullet, A)$$

which is:

(i) a trivial fibration whenever $f^\bullet$ is a Reedy trivial cofibration in $\mathcal{M}^\Delta$, and

(ii) a weak equivalence whenever $f^\bullet$ is a pointwise weak equivalence and $X^\bullet$ and $Y^\bullet$ are Reedy cofibrant.

Proof. The first statement is a special case of Theorem C.5.15 as we now explain. Lemma C.2.12 shows that for any category with products $\mathcal{M}(-, -) : \mathcal{M}^{\text{op}} \times \mathcal{M} \to \text{Set}$ is a right Leibniz bifunctor relative to the (monomorphism, epimorphism) weak factorization system on $\text{Set}$ and any weak factorization system $(\mathcal{L}, \mathcal{R})$ on $\mathcal{M}$. When $\mathcal{M}$ is a model category, the hom bifunctor is then a right Quillen bifunctor relative to the model structure of Exercise C.3.iv.

Now since $\Delta$ is a Reedy category, Theorem C.5.15 tells us that the corresponding bifunctor

$$\mathcal{M}(-, -) : (\mathcal{M}^\Delta)^{\text{op}} \times \mathcal{M} \to \text{Set}^{\Delta^{\text{op}}}$$

is a right Leibniz bifunctor relative to the (trivial cofibration, fibration) weak factorization system on $\mathcal{M}$, the (Reedy trivial cofibration, Reedy trivial fibration) weak factorization system on $\mathcal{M}^\Delta$, and the (Reedy monomorphism, Reedy epimorphism) weak factorization system on $\text{Set}^{\Delta^{\text{op}}}$; by Lemma C.5.9, this latter weak factorization system coincides with the familiar (monomorphism, trivial fibration) weak factorization system. In particular, this bifunctor carries a Reedy trivial cofibration $f^\bullet : X^\bullet \to Y^\bullet$ and a fibration $! : A \to 1$ to a trivial fibration of simplicial sets, exactly as claimed.

The second statement follows from the first by Ken Brown’s Lemma C.1.10. □

C.5.23. Remark. Lemma C.5.22 can be understood as a more primitive result in abstract homotopy theory, which does not require a full model structure on $\mathcal{M}$.

In Lemma C.5.22 and the results on which its proof replies, the model category $\mathcal{M}$ may be replaced by a bicomplete category which has:

(i) a class of weak equivalences $\mathcal{W}$ satisfying the 2-of-3 property,

(ii) a weak factorization system $(\mathcal{C}, \mathcal{F}_I)$, with the class $\mathcal{F}_I$ contained among the weak equivalences,

(iii) so that the class $\mathcal{C} \cap \mathcal{W}$ is closed under coproduct, pushout, and sequential composition.

The notion of Reedy cofibrant and Reedy trivial cofibration can be defined relative to the classes $\mathcal{C}$ and $\mathcal{C} \cap \mathcal{W}$. Then for any object $A$ which admits extensions along maps in $\mathcal{C} \cap \mathcal{W}$, the functor $\mathcal{M}(-, A) : \mathcal{M}^{\text{op}} \to \text{Set}$ carries maps in $\mathcal{C} \cap \mathcal{W}$ to epimorphisms. Since the Reedy trivial cofibrations in $\mathcal{M}^\Delta$ are built as cell complexes from maps in $\mathcal{C} \cap \mathcal{W}$, axiom (iii) and the construction in the proof of Theorem C.5.15 shows that $\mathcal{M}(-, A) : (\mathcal{M}^\Delta)^{\text{op}} \to \text{sSet}$ carries Reedy trivial cofibrations to trivial fibrations of simplicial sets. This proves the first statement of Lemma C.5.22.

For the second statement, we revisit the proof of Lemma C.1.10. By factoring the map $(f, \text{id}) : X^\bullet + Y^\bullet \to Y^\bullet$ using the Reedy weak factorization system built from (ii) we obtain a factorization of the
pointwise weak equivalence \( f : X^\bullet \rightarrow Y^\bullet \) as displayed

\[
\begin{array}{ccc}
  X^\bullet & \sim & Y^\bullet \\
  \downarrow q & & \downarrow f \\
  Z & \leftarrow & \end{array}
\]

\[
\begin{array}{ccc}
  & \nwarrow v & \\
  & & \\
  & \searrow u & \\
  & & \\
  u & \leftarrow & v
\end{array}
\]

where the maps \( u \) and \( v \) are Reedy cofibrations and pointwise weak equivalences and \( v \) is a section of \( q \). Axioms (i) and (iii) give us the result proven in Lemma C.5.13, that the maps \( u \) and \( v \) are Reedy trivial cofibrations. Now the 2-of-3 property assumed in (i) is enough to achieve the conclusion in the second statement of Lemma C.5.22, that \( - \circ f : \mathcal{M}(Y^\bullet, A) \Rightarrow \mathcal{M}(X^\bullet, A) \) is a weak equivalence of simplicial sets, where the “weak equivalences” here can be chosen to be any class of maps of simplicial sets satisfying the 2-of-3 property and containing the maps \( - \circ f : \mathcal{M}(Y^\bullet, A) \Rightarrow \mathcal{M}(X^\bullet, A) \) for those \( f \) that are Reedy in \( C \cap W \).

**Exercises.**

C.5.i. **Exercise.** Prove Lemma C.5.1.

C.5.ii. **Exercise ([98, 14.3.7]).** Prove Lemma C.5.19.

C.5.iii. **Exercise ([98, 14.3.8]).** Prove the relative analog of Lemma C.5.20: if \( X \) and \( Y \) are both unaugmentable cosimplicial objects in a presheaf category, then any pointwise monomorphism \( X \rightarrow Y \) is also a Reedy monomorphism, that is, its relative latching maps are monic.
Appendix of Concrete Calculations
APPENDIX D

The combinatorics of (marked) simplicial sets

In this appendix we explore the combinatorics of simplicial sets, proving results alluded to in Chapters 1 and 4. Certain of these results, namely those involving isomorphisms in quasi-categories, are more easily proved in the closely related category of “marked” simplicial sets, where the quasi-categories are identified with those marked simplicial sets that are \([n\)-complicial\]. Because the corresponding \(n\)-complicial sets provide one of the families of examples of \(\infty\)-cosmoi appearing in Appendix E, we provide full details of the necessary combinatorial results in that more general context.

D.1. Complicial sets

When a quasi-category is regarded as an \((\infty, 1)\)-category, its vertices play the role of the objects and its edges represent the morphisms, with the degenerate edge at a vertex representing its identity. The \(n\)-simplices then witness \(n\)-ary composition relations. When a complicial set is regarded as an \((\infty, \infty)\)-category, its \(n\)-simplices must play a dual role: both serving as witnesses for lower-dimensional composition relations and representing a priori non-invertible \(n\)-dimensional cells in their own right. To disambiguate between these two interpretations, certain positively-dimensional simplices in a complicial set are marked as “thin,” indicating that they should be interpreted as “equivalences” witnessing a weak composition relation between their boundary faces. Thus the ambient category in which complicial sets are defined is not the category of ordinary simplicial sets but a closely related category of marked simplicial sets\(^1\) that we now introduce.

D.1.1. Definition (marked simplicial sets). A marked simplicial set is a simplicial set with a designated subset of marked or thin positive-dimensional simplices that includes all degenerate simplices. A map of marked simplicial sets is a simplicial map that preserves marked simplices.

D.1.2. Definition (minimal and maximal marking). The category \(s\mathbf{Set}^+\) of marked simplicial sets is equipped with an evident forgetful functor to \(s\mathbf{Set}\) admitting both left and right adjoints:

\[
\begin{array}{cccc}
\text{Core} & \downarrow & \downarrow \quad \text{Core} \\
(-)^\flat & \downarrow & \downarrow \quad (-)^\sharp \\
s\mathbf{Set}^+ & \rightarrow & \rightarrow \quad s\mathbf{Set} \\
\text{U} & \downarrow & \downarrow \quad \text{U} \\
\text{ Core} & \rightarrow & \rightarrow \quad \text{ Core} \\
\end{array}
\]

The left adjoint \((-)^\flat\) defines the minimal marking of a simplicial set, in which only the degeneracies are marked, while the right adjoint \((-)^\sharp\) defines the maximal marking, with all simplices marked. This

\(^1\)In the original sources [124, 125], marked simplicial sets are called stratified simplicial sets. To avoid confusing with the increasingly prominent unrelated notion of stratified spaces, we have elected to change the name. Lurie [74] uses the term marked simplicial sets for a special case of the more general notion we presently introduce.

523
functor has a further right adjoint, which takes a marked simplicial set to its core, the simplicial set with the same vertices comprised of those marked simplices all of whose faces are also marked.

On various occasions, it is convenient to identify \( s\text{Set} \) with either of the fully faithful embeddings into \( s\text{Set}^+ \) just introduced. Unless otherwise specified, the default convention is to identify simplicial sets with their minimal markings. In particular, with this convention, we are free to regard the standard simplices and their subspaces as minimally marked simplicial sets.

To succinctly introduce other marked simplicial sets, the following terminology will be convenient:

D.1.3. Definition. An inclusion \( U \rightarrow V \) of marked simplicial sets is:

- **regular**, denoted \( U \rightarrow_r V \), if thin simplices in \( U \) are created in \( V \) and
- **entire**, denoted \( U \rightarrow_e V \), if the map is an isomorphism (or more commonly the identity) on underlying simplicial sets, in which case the only difference between \( U \) and \( V \) is that \( V \) has more marked simplices.

For example, for each \( n \geq 1 \), we define the **marked simplex** \( \Delta[n]_t \) to be the entire extension of minimally marked simplex \( \Delta[n] \) that also marks the top non-degenerate simplex.

Let \( \Delta \hookrightarrow s\text{Set}^+ \) denote the full subcategory spanned by the minimally marked simplices \( \Delta[n] \), for \( n \geq 0 \), together with the marked simplices \( \Delta[n]_t \), for \( n \geq 1 \). It can be built from the simplex category \( \Delta \) of Notation 1.1.1 by:

- adjoining objects \([n]_t\) for \( n \geq 1 \),
- adjoining maps \( \phi : [n] \to [n]_t \) for \( n \geq 1 \) and \( \zeta^i : [n + 1]_t \to [n] \) for \( n \geq 0 \) and \( 0 \leq i \leq n \), and
- imposing relations \( \zeta^i \phi = \sigma^i \) and \( \sigma^i \zeta^{i+1} = \zeta^i \sigma^i \) for \( i \leq j \).

For a marked simplicial set \( X \), the maps \( \Delta[n] \to X \) and \( \Delta[n]_t \to X \) respectively parametrize \( n \)-simplices in \( X \) and marked \( n \)-simplices in \( X \). This defines a canonical embedding \( s\text{Set}^+ \hookrightarrow \text{Set}^{t\Delta_{op}} \), which is easily seen to be fully faithful. Moreover:

D.1.4. Proposition. There is a reflective fully faithful embedding

\[
\text{Set}^{t\Delta_{op}} \hookrightarrow s\text{Set}^+ \\
\]

whose

(i) essential image consists of those presheaves \( F \) for which the component maps \(- \circ \phi : F_{[n]}_t \to F_{[n]} \) are monomorphisms, and

(ii) left adjoint is constructed by replacing the set \( F_{[n]}_t \) with the image of the map \(- \circ \phi : F_{[n]}_t \to F_{[n]} \).

Consequently, \( s\text{Set}^+ \) is a locally finitely presentable category, and in particular is complete and cocomplete, with limits constructed pointwise as presheaves in \( \text{Set} \) and with colimits constructed by applying the reflector to the pointwise colimit of presheaves.

Put in more elementary terms, limits and colimits of marked simplicial sets are created by the underlying simplicial set functor \( U : s\text{Set}^+ \to s\text{Set} \). A simplex in the limit is marked if and only if each of its components, defined by composing with the legs of the limit cone, are marked simplices. A simplex in a colimit is marked if any of its lifts along any leg of the colimit cone are marked simplices. The reflection in (ii) is a sort of “propositional truncation,” remembering which simplices should be marked while forgetting the data that indicates why.

\(^\text{Viktoriya Ozornova and Martina Rovelli pointed out to us that this last family of relations was omitted from the original source \([118]\) but should have been included. A corrected definition appears in \([86, 1.1]\).}\)
Proof. The right action of the operators in $t\Delta$ on a presheaf $F \in \mathbf{Set}^{t\Delta^{\text{op}}}$ gives the sets of elements of $F$ the structure of a marked simplicial set with the exception of one condition: namely that the marked $n$-simplices form a subset of the $n$-simplices. This explains the condition appearing in (i) and the construction appearing in (ii). It follows that marked simplicial sets are the category of models for a finite limit sketch, and hence form a locally finitely presentable category. Any reflective full subcategory of a complete and cocomplete category inherits limits in the manner constructed in the statement; see eg [99, 4.5.15].

Lemma C.5.9 extends to marked simplicial sets as follows:

D.1.5. Lemma. The momomorphisms in $\mathbf{sSet}^+$ are cellularly generated by

$$\{\partial \Delta[n] \hookrightarrow \Delta[n]\}_{n \geq 0} \cup \{\Delta[n] \hookrightarrow e \Delta[n]\}_{n \geq 1}.$$  

Proof. Exercise D.1.i. □

A marked simplicial set is a simplicial set with enough structure to talk about composition of simplices in all dimensions. A complicial set is a marked simplicial set in which composites exist and in which thin witnesses to composition compose to define thin simplices, an associativity condition that will ultimately imply that thin simplices are equivalences in a sense that will be made explicit in §D.7. The following form of the definition of a (nee. weak) complicial set, due to Verity [125], modifies an earlier equivalent presentation due to Street [114]. Verity’s modification focuses on a particular set of $k$-admissible $n$-simplices, which are thin $n$-simplices that exhibit their $k$th face as a composite of their $(k + 1)$th and $(k - 1)$th faces, in the case where $0 < k < n$. In the case $k = 0$ or $k = n$, a $k$-admissible $n$-simplex witnesses an equivalence between the first or last pair of faces, respectively.

D.1.6. Definition ($k$-admissible $n$-simplex). For $n \geq 1$ and $0 \leq k \leq n$, the $k$-admissible $n$-simplex $\Delta^k[n]$ is the entire superset of the standard $n$-simplex with certain additional faces marked thin: a non-degenerate $m$-simplex in $\Delta^k[n]$ is thin if and only if it contains all of the vertices $\{k-1,k,k+1\} \cap [n]$. Thin faces include in particular:

- the top dimensional $n$-simplex
- all codimension-one faces except for the $(k - 1)$th, $k$th, and $(k + 1)$th
- the 2-simplex spanned by $[k-1,k,k+1]$ when $0 \leq k \leq n$ or the edge spanned by $[k-1,k,k+1] \cap [n]$ when $k = 0$ or $k = n$.

When drawing pictures of marked simplicial sets, we use the symbol “$\simeq$” to decorate marked simplices and “$\sim$” to decorate marked edges. Our diagrams will also adopt a convention for the direction of the cells inhabiting an unmarked $n$-simplex. Following the combinatorics introduced by Street in his “Algebra of oriented simplexes” [114], we regard an $n$-simplex as an $n$-cell from the pasted composite of its odd-numbered faces to the pasted composite of its even-numbered faces. Note this is compatible with the convention already in use for depicting a 1-simplex in a simplicial set as an arrow from its 1st face (the 0th vertex) to its 0th face (the 1st vertex).

D.1.7. Example (admissible simplices in low dimensions).

(i) For $n = 1$, both admissible simplices $\Delta^0[1]$ and $\Delta^1[1]$ equal the thin 1-simplex $\Delta[1]_t = \Delta[1]^\#$. A map $\Delta[1]^\# \to A$ is interpreted as defining an equivalence between the two vertices in its image.

³More exactly, Street defines a strict $n$-category $O_n$, which he refers to as the $n$-th oriental to be the free strict $n$-category generated by an $n$-simplex and its faces, with the orientation conventions described here.
(ii) For \( n = 2 \), the admissible simplex \( \Delta^1[2] = \Delta[2]_t \), the thin 2-simplex. A map \( \Delta^1[2] \to A \) is interpreted as specifying that the image of the \( \{02\} \)-edge is a composite of the images of the \( \{01\}- \) and \( \{12\} \)-edges.

By contrast, \( \Delta^0[2] \) and \( \Delta^2[2] \) each have a marked edge, as well as a marked 2-simplex as indicated by the diagrams:

\[
\Delta^0[2] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{\gamma} & \xleftarrow{\gamma} & \xleftarrow{\gamma} \\
\end{array} \quad \Delta^1[2] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{\gamma} & \xleftarrow{\gamma} & \xleftarrow{\gamma} \\
\end{array} \quad \Delta^2[2] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{\gamma} & \xleftarrow{\gamma} & \xleftarrow{\gamma} \\
\end{array}
\]

A map \( \Delta^0[2] \to A \) witnesses a homotopy between the image of the \( \{12\} \) edge and the image of the \( \{02\} \) edge.

(iii) For \( n = 3 \), the admissible simplices \( \Delta^4[3] \) and \( \Delta^2[3] \) have their 3rd and 0th faces marked, respectively, as well as the top dimensional 3-simplex, with no other non-degenerate faces marked. We choose to draw admissible 3-simplices in such a way that allows us to see all of their codimension-one faces:

\[
\Delta^2[3] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{g} & \xleftarrow{\alpha} & \xleftarrow{\beta} \\
\xrightarrow{\eta} & \xleftarrow{\eta} & \xleftarrow{\eta} \\
\xrightarrow{f} & \xleftarrow{f} & \xleftarrow{f} \\
\xrightarrow{\ell} & \xleftarrow{\ell} & \xleftarrow{\ell} \\
\end{array} \quad \Delta^3[3] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{g} & \xleftarrow{\alpha} & \xleftarrow{\beta} \\
\xrightarrow{\eta} & \xleftarrow{\eta} & \xleftarrow{\eta} \\
\xrightarrow{f} & \xleftarrow{f} & \xleftarrow{f} \\
\xrightarrow{\ell} & \xleftarrow{\ell} & \xleftarrow{\ell} \\
\end{array}
\]

Here we’ve labelled faces in such a way that allows us to better describe the interpretation of a map \( \Delta^2[3] \to A \). Its 0th face, which itself an admissible simplex \( \Delta^1[2] \), witnesses that the edge \( \{13\} \) is a composite of the edges \( \{12\} \) and \( \{23\} \). Note that because the 0th face is thin, its 1st edge is interpreted as a composite \( k \beta \) of \( g \) and \( k \), which is needed so that the boundary of the 2-cell appearing in the 2nd face agrees with the boundary of the pasted composite of \( \beta \) and \( \alpha \). On account of this boundary condition and the thin 3-simplex, we interpret the 2nd face as the pasted composite of the 1st and 3rd faces depicted on the right.

The admissible simplex \( \Delta^0[3] \) has both its 2nd and 3rd faces marked, as well as the top dimensional 3-simplex, and the edge \( \{01\} \). Dually, \( \Delta^3[3] \) has its 0th and 1st faces marked, as well as the top dimensional 3-simplex, and the edge \( \{23\} \).

\[
\Delta^0[3] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{e} & \xleftarrow{\nu} & \xleftarrow{\mu} \\
\xrightarrow{f} & \xleftarrow{a} & \xleftarrow{b} \\
\xrightarrow{h} & \xleftarrow{h} & \xleftarrow{h} \\
\end{array} \quad \Delta^3[3] := \begin{array}{ccc}
0 & \xrightarrow{1} & 2 \\
\xrightarrow{e} & \xleftarrow{\nu} & \xleftarrow{\mu} \\
\xrightarrow{f} & \xleftarrow{a} & \xleftarrow{b} \\
\xrightarrow{h} & \xleftarrow{h} & \xleftarrow{h} \\
\end{array}
\]

A map \( \Delta^0[3] \to A \) is interpreted as witnessing a homotopy between the pair of non-thin 2-simplices occupying the 0th and 1st faces, respectively.

D.1.8. REMARK (the odd dual). Recall that the opposite of a simplicial set \( X \) is the simplicial set obtained by reindexing along the involution \( (-)^{op} : \Delta \to \Delta \) that reverses the ordering in each ordinal. This operation may be extended to marked simplicial sets in a natural way: marking an \( n \)-simplex in \( X^{op} \) just when the corresponding \( n \)-simplex in \( X \) is marked. Note, however, that under Street’s interpretation of an \( n \)-simplex as encoding an \( n \)-dimensional morphism from the composite of its
odd \((n - 1)\)-dimensional faces to the composite of its even \((n - 1)\)-dimensional faces, this operation doesn’t simply “reverse the direction of all the cells” in a marked simplicial set. Rather, it reverses the direction of all the simplices in the odd dimensional cells, while preserving the direction in all of the even dimensional cells. This is because the odd-dimensional simplices have an even number of codimension-one faces, so reversing their labeling exchanges the groups of “odd” and “even” faces, while even-dimensional simplices have an odd number of codimension-one faces, so the “odd” and “even” groupings are preserved. Thus, we refer to the vertex reordering construction as defining the \textbf{odd dual} of a marked simplicial set.

\section{Definition} A \textbf{complicial set} is a marked simplicial set that admits extensions along the \textbf{elementary anodyne extensions}, which are given by the following two sets of maps:

(i) The \textbf{complicial horn extensions}

\[
\begin{array}{c}
\Lambda^k[n] \hookrightarrow \Delta^k[n] \quad \text{for} \quad n \geq 1, \ 0 \leq k \leq n
\end{array}
\]

are regular inclusions of \(k\)-admissible \(n\)-horns. An inner admissible \(n\)-horn parametrizes “admissible composition” of a pair of \((n - 1)\)-simplices. The extension defines a composite \((n - 1)\)-simplex together with a thin \(n\)-simplex witness.

\[
\begin{array}{c}
\Lambda^k[n] \longrightarrow A \\
\downarrow \\
\Delta^k[n]
\end{array}
\]  

(D.1.10)

(ii) The \textbf{complicial thinness extensions}

\[
\begin{array}{c}
\Delta^k[n] \prime \hookrightarrow \Delta^k[n] \” \quad \text{for} \quad n \geq 2, \ 0 \leq k \leq n,
\end{array}
\]

are entire inclusions of two entire supersets of \(\Delta^k[n]\). The marked simplicial set \(\Delta^k[n] \prime\) is obtained from \(\Delta^k[n]\) by also marking the \((k - 1)\)th and \((k + 1)\)th faces, while \(\Delta^k[n] \”\) has all codimension-one faces marked. This extension problem

\[
\begin{array}{c}
\Delta^k[n] \prime \longrightarrow A \\
\downarrow \\
\Delta^k[n] \”
\end{array}
\]  

(D.1.11)

demands that whenever the composable pair of simplices in an admissible horn are thin, then so is any composite.

\section{Example} (complicial horn extensions). For \(\Lambda^2[4] \hookrightarrow \Delta^2[4]\) the non-thin codimension-one faces in the horn define the two 3-simplices with a common face displayed on the left, while their composite is a 3-simplex as displayed on the right.
It makes sense to interpret the right hand simplex, the 2nd face of the 2-admissible 4-simplex, as a composite of the 3rd and 1st faces because the 2-simplex

\[ \begin{array}{ccc}
1 & 2 & 3 \\
\downarrow & & \downarrow \\
0 & 2 & 4 \\
\end{array} \]

is thin.

We refer to the maps that are cellurally generated by the elementary anodyne extensions as **marked anodyne extensions**. For instance, by a mild extension of the argument that solves Exercise 1.1.v:

D.1.13. **Lemma.** Either injection \( \mathbb{I}^\sharp \hookrightarrow \mathbb{I} \) of the marked 1-simplex into the maximally marked isomorphism is an marked anodyne extension, as is the injection \( \mathbb{I} \hookrightarrow \mathbb{I}^\sharp \).

**Proof.** Exercise D.1.iv. \( \square \)

D.1.14. **Definition.** A map of marked simplicial sets is a **complicial isofibration** if it has the right lifting property with respect to the elementary anodyne extensions and if its domain and codomain are complicial sets.

By Exercise D.1.v, a marked map between complicial sets is a complicial isofibration if and only if it lifts against the complicial horn extensions. Of course, complicial isofibrations will then enjoy the right lifting property against all marked anodyne extensions. Among the complicial isofibrations are the **trivial fibrations**, defined to be those maps of marked simplicial sets that lift against the monomorphisms, as characterized by Lemma D.1.5.

The original meaning of “complicial sets” referred to a particular variety that we now call **strict**.

D.1.15. **Definition.** A **strict complicial set** is a marked simplicial set that admits unique extensions along the elementary anodyne extensions (D.1.10) and (D.1.11).

In the manuscript [124], Verity proves that the strict complicial sets are precisely those marked simplicial sets that are Street nerves of strict \( \omega \)-categories, resolving a conjecture of Street and Roberts. In this manuscript, we will primarily utilize marked simplicial sets to streamline the proofs of results concerning isomorphisms in quasi-categories and equivalences between quasi-categories. We will discuss this topic more explicitly in §D.4 and §D.7 after developing some combinatorial constructions we will require in the interim. We conclude this section with one final definition.

D.1.16. **Definition.** A **marked homotopy** between a pair of maps \( f, g : X \to Y \) is given by a map \( \alpha : X \times \Delta[1]^\sharp \to Y \) that restricts along the endpoint inclusions \( X + X \hookrightarrow_r X \times \Delta[1]^\sharp \) to the maps \( f \) and \( g \), respectively. In the case where \( X \) and \( Y \) are minimally marked simplicial sets, a map
\(X \times \Delta[1] \to Y\) extends to a map \(X \times \Delta[1]^\# \to Y\) just when for each 0-simplex \(x \in X\), the 1-simplex \((x \cdot \sigma^0, \text{id}_Y) \in X \times \Delta[1]^\#\) maps to a degenerate and hence marked 1-simplex of \(Y\). ⁴

A marked homotopy equivalence consists of:
• a pair of marked maps \(f : X \to Y\) and \(g : Y \to X\) and
• a pair of marked homotopies \(\alpha : X \times \Delta[1]^\# \to X\) and \(\beta : Y \times \Delta[1]^\# \to Y\) between \(\text{id}_X\) and \(gf\) and \(fg\) and \(\text{id}_Y\), respectively.

This definition works best when \(X\) and \(Y\) are complicial sets, in which case marked homotopies can be reserved and composed. Even when this is not the case, we permit ourselves the reverse the direction of the marked homotopies that comprise a marked homotopy equivalence without comment.

D.1.17. **Digression** (the Verity model structure for complicial sets). The category of marked simplicial sets bears a cartesian closed, cofibrantly generated model structure whose fibrant objects are exactly the complicial sets and whose cofibrations are the monomorphisms [125, §6.2-4]. The fibrations and weak equivalences between fibrant objects are precisely the classes of complicial isofibrations and marked homotopy equivalences defined above. In the following sections, we verify many of these properties for the category of fibrant objects directly, leaving only the verification of the actual model structure, which follows from Jeff Smith’s theorem, to the literature.

**Exercises.**

D.1.i. **Exercise.** Prove Lemma D.1.5.

D.1.ii. **Exercise.** Prove that a maximally marked simplicial set defines a complicial set if and only if the underlying simplicial set is a Kan complex.

D.1.iii. **Exercise.** Prove that the underlying simplicial set of any complicial set in which all simplices of dimension greater than 1 are marked is a quasi-category. ⁵

D.1.v. **Exercise.** Let \(f : A \to B\) be any map of marked simplicial sets whose domain \(A\) is a complicial set. Prove that \(f\) has the (unique) right lifting property against the complicial thinness extensions.

**D.2. The join and slice constructions**

In this section, we revisit Joyal’s join and slice constructions in considerably more detail than given in Definition 4.2.4 and discuss their extension to marked simplicial sets. We prove that Leibniz joins of monomorphisms and various classes of anodyne maps again define monomorphisms of the same type. The combinatorics are slightly easier if we work with augmented simplicial sets in place of ordinary simplicial sets, an approach that follows the original definition of the simplicial join by Ehlers and Porter [39].

D.2.1. **Definition** (ordinal sum). The algebraists’ skeletal category \(\Delta_+\) of finite ordinals and order preserving maps — with objects \([n] = \{0 \leq 1 \leq \cdots \leq n\}\) and \([-1] = \emptyset\) — supports a strict (non-symmetric) monoidal structure \((\Delta_+, \oplus, [-1])\) in which \(\oplus\) denotes the **ordinal sum** given

\[
\text{for objects } [n], [m] \in \Delta_+ \text{ by } [n] \oplus [m] := [n + 1 + m].
\]

⁴The cartesian product of marked simplicial sets is described in more detail in Proposition D.3.4.

⁵A converse of sorts to this result will appear in Theorem D.4.13.
• for arrows $\alpha: [n] \to [n'], \beta: [m] \to [m']$ by $\alpha \oplus \beta: [n + 1 + m] \to [n' + 1 + m']$ defined by

$$\alpha \oplus \beta(i) = \begin{cases} 
\alpha(i) & \text{if } i \leq n, \\
\beta(i - n - 1) + n' + 1 & \text{otherwise.}
\end{cases}$$

By Day convolution [33], the join bifunctor $\oplus: \Delta_+ \times \Delta_+ \to \Delta_+$ extends to a (non-symmetric) monoidal closed structure

$$(sSet_+, \star, \Delta[-1], \text{dec}_l, \text{dec}_r)$$
on the category of augmented simplicial sets $sSet_+ := Set^{\Delta_+^{op}}$.

D.2.2. Definition (join of augmented simplicial sets). The join $X \star Y$ of augmented simplicial sets $X$ and $Y$ may be described explicitly as follows:

• it has simplices pairs $(x, y) \in (X \star Y)_{r+1+s}$ with $x \in X_r$, $y \in Y_s$,

• if $(x, y)$ is a simplex of $X \star Y$ with $x \in X_r$ and $y \in Y_s$ and $\alpha: [n] \to [r + 1 + s]$ is a simplicial operator in $\Delta_+$, then $\alpha$ may be uniquely decomposed as $\alpha = \alpha_1 \oplus \alpha_2$ with $\alpha_1: [n_1] \to [r]$ and $\alpha_2: [n_2] \to [s]$, and we define $(x, y) \cdot \alpha := (x \cdot \alpha_1, y \cdot \alpha_2)$.

Note by construction that $\Delta[n] \star \Delta[m] \cong \Delta[n + 1 + m]$, since $[n] \oplus [m] = [n + 1 + m]$.

D.2.3. Definition (décalage of augmented simplicial sets). The closures $\text{dec}_l$ and $\text{dec}_r$, known as the left and right décalage constructions, respectively, are defined as the parametrized right adjoints to the join: to fix handedness, we denote the adjoints, for each augmented simplicial set $X$, by

$sSet_+ \xrightarrow{s_X^*} sSet_+$ and $sSet_+ \xleftarrow{s_X^*} sSet_+$

Collectively, the bifunctors

$sSet_+ \times sSet_+ \xrightarrow{s_X^*} sSet_+$, $sSet_+ \times sSet_+ \xrightarrow{s_X^{op}} sSet_+$, $sSet_+ \times sSet_+ \xrightarrow{\text{dec}_l \cdot (-)} sSet_+$, $sSet_+ \times sSet_+ \xrightarrow{\text{dec}_r \cdot (-)} sSet_+$
define a two-variable adjunction and as such preserve limits and colimits in each variable separately.

D.2.4. Observation (simplicial sets vs augmented simplicial sets). The evident functor that forgets the augmentation $U: sSet_+ \to sSet$ admits both left and right adjoints

$sSet_+ \xleftarrow{\pi_0} sSet \xrightarrow{U} sSet_+$

where the left adjoint augments a simplicial set $X$ with its set of path components $\pi_0 X$, defined by the coequalizer

$$X_1 \xrightarrow{\delta^1} X_0 \xrightarrow{\delta^0} \pi_0 X$$

and the right adjoint augments a simplicial set “trivially” by adding a single $-1$-simplex. The unit of $\pi_0 \dashv U$ and counit of $U \dashv *$ are both isomorphisms; hence either adjoint defines a fully faithful embedding $sSet \hookrightarrow sSet_+$.

A general feature of the Day convolution product is that the Yoneda embedding $\Delta_+ \hookrightarrow Set^{\Delta_+^{op}}$ defines a strong monoidal functor.
Any augmented simplicial set is canonically a coproduct of its terminally-augmented “components”:

D.2.5. **Lemma.** Let $X$ be an augmented simplicial set and let $x \in X_{-1}$.

(i) The subset comprised of those simplices in any dimension whose $-1$-simplex face is $x$ forms a terminally augmented simplicial subset of $X$.

(ii) The disjoint union of these components is isomorphic to $X$.

Thus, any augmented simplicial set $X$ admits a canonical decomposition into a coproduct of terminally augmented simplicial sets indexed by the set $X_{-1}$.

**Proof.** Exercise D.2.i. 

D.2.6. **Definition** (join of simplicial sets). By convention, the join of a pair of simplicial sets is defined to be the underlying simplicial set of the trivially augmented simplicial sets. Thus, the join bifunctor is the composite

$$sSet \times sSet \xrightarrow{- \star -} sSet$$

Explicitly, $n$-simplices of $X \star Y$ are pairs comprised of a $j$-simplex of $X$ and a $k$-simplex of $Y$ where $j + k = n - 1$, where in the case $j = -1$ such a “pair” consists of a single $n$-simplex of $Y$ and in the case $k = -1$ such a “pair” consists of a single $n$-simplex of $X$. This recovers the definition given in 4.2.4.

As observed in Definition 4.2.4, the join of simplicial sets $X$ and $Y$ admits canonical embeddings

$$X \hookrightarrow X \star Y \hookleftarrow Y$$

which can be understood as the maps obtained by applying $X \star -$ or $- \star Y$ respectively to the maps $\Delta[-1] \to Y$ and $\Delta[-1] \to X$ in $sSet_+$ that pick out the unique $-1$-simplices in the trivial augmentations.

D.2.7. **Lemma.**

(i) The join bifunctor $- \star -$ : $sSet \times sSet \to sSet$ preserves connected colimits in each variable separately.

(ii) For any simplicial set $X$, the join functors

$$sSet \xrightarrow{\star} X/sSet \quad \text{and} \quad sSet \xrightarrow{- \star X} X/sSet$$

preserve all colimits.

**Proof.** In Definition D.2.6, the join of simplicial sets is defined as the composite of three functors, two of which possess right adjoints and hence preserve all colimits. The third functor $*: sSet \to sSet_+$ does not possess a right adjoint but nevertheless preserves connected colimits as is clear from the following definition: an indexing 1-category $J$ is connected just when the colimit of the constant $J$-indexed diagram valued at the singleton set is a singleton. This proves (i).

Now the forgetful functor $X/sSet \to sSet$ strictly creates connected colimits [99, 3.3.8], so the join functors of (ii) preserve connected colimits. Arbitrary colimits may be built from connected colimits and coproducts, so to prove (ii) it remains only to argue that these functors preserve coproducts. While $X \star (\coprod_i Y_i) \neq \coprod_i (X \star Y_i)$ if the latter coproduct is interpreted in $sSet$, it can be directly verified that $X \star (\coprod_i Y_i)$ is the quotient of $\coprod_i (X \star Y_i)$ modulo the identification of the image of each inclusion $X \hookrightarrow X \star Y_i$ with a single copy of $X$, which is exactly the construction of the coproduct in the category $X/sSet$. 

\[531\]
D.2.8. Definition (slice of simplicial sets). The categories $\text{sSet}$ and $\text{X/sSet}$ are locally presentable (see [1, 1.57]), so the cocontinuous functors of Lemma D.2.7(ii) have right adjoints

$$
\text{X} \star - \quad \text{sSet} \quad \bot \quad \text{X/sSet} \quad \text{X} \star - \quad \text{sSet} \quad \bot \quad \text{X/sSet}
$$

the values of which at $f: X \to A$ define Joyal’s sliced simplicial sets $f/\text{A}$ and $A_f$ characterized by the universal properties

$$
\left\{ \begin{array}{l}
X \star Y \quad \xrightarrow{f} \quad A \\
X \star \Delta[-1] \quad \xrightarrow{f} \quad A
\end{array} \right\} \cong \left\{ Y \to f/A \right\} \quad \text{and} \quad \left\{ \begin{array}{l}
Y \star X \quad \xrightarrow{f} \quad A \\
Y \star \Delta[-1] \quad \xrightarrow{f} \quad \text{dec}_r(X, A)
\end{array} \right\} \cong \left\{ Y \to A_f \right\}.
$$

See Proposition 4.2.5.

We think of the slice $f/\text{A}$ as being the simplicial set of cones under the diagram $f$ and we think of the dual slice $A_f$ as being the simplicial set of cones over the diagram $f$. This terminology will be reconciled with the terminology of Definition 4.2.1 in Proposition D.6.5. We can also recover these sliced simplicial sets from the décalage construction of Definition D.2.3 via Lemma D.2.5:

D.2.9. Lemma. For any map $f: X \to A$ of simplicial sets, the simplicial sets $f/\text{A}$ and $A_f$ are the terminally augmented components of $\text{dec}_l(X, A)$ and $\text{dec}_r(X, A)$, respectively, indexed by the $-1$-simplex $f: X \to A$.

Proof. We identify simplicial sets $X$ and $A$ with their terminally augmented simplicial sets. Recall that $\Delta[-1]$ is the monoidal unit for the join bifunctor on $\text{sSet}_+$ . Consequently, by adjunction, maps $\Delta[-1] \to \text{dec}_l(X, A)$ or $\Delta[-1] \to \text{dec}_r(X, A)$ correspond to maps $X \to A$. For another terminally augmented simplicial set $Y$, transposing across the adjunction of Definition D.2.3 provides a correspondence:

$$
\left\{ \begin{array}{l}
X \star \Delta[-1] \quad \cong \quad X \\
X \star Y \quad \xrightarrow{f} \quad A
\end{array} \right\} \cong \left\{ \begin{array}{l}
\Delta[-1] \quad \xrightarrow{f} \quad \text{dec}_l(X, A)
\end{array} \right\}
$$

which shows that the simplicial subset of $\text{dec}_l(X, A)$ comprised of those simplices whose $-1$-simplex face is $f$ has the universal property that defines $f/\text{A}$. The dual argument proves that the simplicial subset of $\text{dec}_r(X, A)$ comprised of those simplices whose $-1$-simplex face is $f$ has the universal property that defines $A_f$. In other words, these décalages admit the following canonical decompositions as disjoint unions of (terminally augmented) slices:

$$
\text{dec}_r(X, A) = \bigsqcup_{f: X \to A} A_f \quad \text{dec}_l(X, A) = \bigsqcup_{f: X \to A} f/A
$$

D.2.10. Definition ((left-/right-/inner-)anodyne extensions).

- The set of horn inclusions $\Lambda^k[n] \hookrightarrow \Delta[n]$ for $n \geq 1$ and $0 \leq k \leq n$ cellularly generates the anodyne extensions.
- The set of left horn inclusions $\Lambda^k[n] \hookrightarrow \Delta[n]$ for $n \geq 1$ and $0 \leq k < n$ cellularly generates the left anodyne extensions.
• The set of right horn inclusions $\Lambda^k[n] \hookrightarrow \Delta[n]$ for $n \geq 1$ and $0 < k \leq n$ cellurally generates the right anodyne extensions.

• The set of inner horn inclusions $\Lambda^k[n] \hookrightarrow \Delta[n]$ for $n \geq 2$ and $0 < k < n$ cellurally generates the inner anodyne extensions.

We refer to the right classes generated by these maps as left, right, and inner fibrations, respectively. By an easy direct calculation:

**D.2.11. Lemma.** The Leibniz join of a horn inclusion and a boundary inclusion is isomorphic to a single horn inclusion:

$$(\Lambda^k[n] \hookrightarrow \Delta[n]) \ast (\partial \Delta[m] \hookrightarrow \Delta[m]) \cong \Lambda^k[n + 1 + m] \hookrightarrow \Delta[n + 1 + m]$$

$$(\partial \Delta[n] \hookrightarrow \Delta[n]) \ast (\Lambda^k[m] \hookrightarrow \Delta[m]) \cong \Lambda^{n+k+1}[n + 1 + m] \hookrightarrow \Delta[n + 1 + m]$$

**Proof.** Since the join bifunctor is the Day convolution of the ordinal sum $[n] \oplus [m] = [n + 1 + m]$, $\Delta[n] \ast \Delta[m] \cong \Delta[n + 1 + m]$. The domain of the first Leibniz tensor is the simplicial set

$$\Lambda^k[n] \ast \Delta[m] \cup_{\Lambda^k[n] \ast \partial \Delta[m]} \Delta[n] \ast \partial \Delta[m].$$

From the explicit description of the simplices contained in the join given in Definition D.2.2, is plainly a simplicial subset of $\Delta[n + 1 + m]$. Since $\partial \Delta[m]$ contains all the codimension-one faces of $\Delta[m]$, the $\Delta[n] \ast \partial \Delta[m]$ component contains the $j$th face of $\Delta[n + 1 + m]$ for each index $j > n$. Similarly, since $\Lambda^k[n]$ contains all codimension-one faces of $\Delta[n]$ except one, the $\Lambda^k[n] \ast \Delta[m]$ component contains the $i$th face of $\Delta[n + 1 + m]$ for each index $i \leq n$ except $i = k$. Thus, we see that only the $k$th face and the $n + 1 + m$-simplex are missing, which allows us to identify the domain of this Leibniz join with the horn $\Lambda^k[n + 1 + m]$. The dual argument proves the second claimed isomorphism. □

Lemma D.2.11 reveals that the Leibniz join of an inner horn with a boundary inclusion is an inner horn. Consequently:

**D.2.12. Corollary.** If $f: X \to A$ is any simplicial map and $A$ is a quasi-category, then $f/A$ and $A/f$ are quasi-categories.

**Proof.** By Proposition C.2.9(vi) and Lemma C.5.9, the Leibniz join of an inner horn inclusion with a monomorphism gives a map in the class that is cellurally generated by the inner horn inclusions. By Proposition C.2.9(ii), for any quasi-category $A$ and simplicial set $X$, the augmented simplicial sets $\text{dec}_q(X, A)$ and $\text{dec}_r(X, A)$ then admit fillers for all inner horns, considered as trivially augmented simplicial sets. By Lemma D.2.9, it follows that for any simplicial map $f: X \to A$, the slices $f/A$ and $A/f$ are quasi-categories. □

Our next aim is to prove that the slice quasi-categories are equivalent to the quasi-categories of cones introduced in §4.2. As sketched there, this result hinges on a suitable equivalence between the join construction and the so-called “fat join” construction of Definition 4.2.2, which we now extend to augmented simplicial sets. Recall from Lemma D.2.5 that an augmented simplicial set $X$ canonically decomposes into a coproduct $X \cong \bigsqcup_{i \in X_{-1}} X^i$ of terminally augmented simplicial sets, indexed by the set of $-1$-simplices.
D.2.13. **Definition** (fat join and décalage of augmented simplicial sets). For augmented simplicial sets \( X \cong \sqcup_{i \in X} X_i \) and \( Y \cong \sqcup_{j \in Y} Y_j \) their **fat join** is constructed by the pushout:

\[
\begin{array}{ccc}
(X \times Y) \cup (X \times Y) & \xrightarrow{\pi_{\text{Y-Lin}}} & (X \times Y_{-1}) \cup (X_{-1} \times Y) \\
\downarrow & & \downarrow r \\
X \times 2 \times Y & \xrightarrow{\pi} & X \diamond Y
\end{array}
\]

\[
i.e., \quad X \circ Y := \bigsqcup_{(i,j) \in X \times Y_{-1}} X^i \circ Y^j
\]

where \( X^i \circ Y^j \) is the terminally augmented simplicial set corresponding to the fat join of Definition 4.2.2.

This construction is arranged so that the bifunctor \(- \circ - : \text{sSet}_+ \times \text{sSet}_+ \to \text{sSet}_+\) preserves all colimits in each variable, not simply the connected ones preserved by the bifunctor \(- \circ - : \text{sSet} \times \text{sSet} \to \text{sSet}\).

Explicitly, the set of \( n \)-simplices \( (X \circ Y)_n \) is the quotient of the set \( X_n \times \Delta([n],[1]) \times Y_n \) of \( n \)-simplices of \( X \times 2 \times Y \) modulo the relation that identifies triples

- \((x,0,y) \sim (x,0,y')\) where \(0 : [n] \to [1]\) is the constant operator and \(y\) and \(y'\) are in the same component of \( Y \cong \sqcup_{j \in Y} Y_j \) and
- \((x,1,y) \sim (x',1,y)\) where \(1 : [n] \to [1]\) is the constant operator and \(x\) and \(x'\) are in the same component of \( X \cong \sqcup_{i \in X} X_i \).

By cocontinuity and the adjoint functor theorems, the fat join bifunctor on \( \text{sSet}_+ \) has both left and right closures \( \text{fatdec}_l(X,A) \) and \( \text{fatdec}_r(X,A) \), called **left and right fat décalage** respectively, which notation we fix by declaring that if \( X \) is an augmented simplicial set then \( X \diamond - \dashv \text{fatdec}_l(X,-) \) and \(- \diamond X \dashv \text{fatdec}_r(X,-)\).

There is a canonical comparison map from the fat join to the join as previewed in the discussion surrounding Proposition 4.2.7.

D.2.14. **Lemma.** There exists a canonical map of augmented simplicial sets

\[
s^{X,Y} : X \circ Y \to X \star Y
\]

natural in \( X \) and \( Y \) that in particular defines a natural transformation

\[
s^{n,m} : \Delta[n] \circ \Delta[m] \to \Delta[n] \star \Delta[m] \in \text{sSet}_{\Delta^+ \times \Delta^+}
\]

that is an isomorphism if \( n \) or \( m \) equals \(-1\) and otherwise arises as a quotient of the map \( s^{n,m} : \Delta[n] \times \Delta[1] \times \Delta[m] \to \Delta[n+1+m] \) defined by its order-preserving action on vertices:

\[
s^{n,m}(i,j,k) = \begin{cases} 
  i & \text{if } j = 0, \\
  k + n + 1 & \text{if } j = 1.
\end{cases} \tag{D.2.15}
\]

**Proof.** Identifying the set \( X_{-1} \) with the augmented simplicial set \( \sqcup_{X_{-1}} \Delta[-1] \), the Yoneda lemma supplies a canonical map \( X_{-1} \to X \) of augmented simplicial sets, which gives rise to a canonical map

\[
\begin{array}{ccc}
(X \times Y) \cup (X \times Y) & \xrightarrow{\pi_{\text{Y-Lin}}} & (X \times Y_{-1}) \cup (X_{-1} \times Y) \\
\downarrow & & \downarrow r \\
X \times 2 \times Y & \xrightarrow{\pi} & X \circ Y \xrightarrow{s^{X,Y}} X \star Y
\end{array}
\]
Note that the fibers of both $X \diamond Y$ and $X \star Y$ over the endpoints $0, 1$ of $2$ are $X \times Y_{-1}$ and $X_{-1} \times Y$ respectively, and the map $s^{X,Y}$ commutes with the inclusions of these fibers.

The map $s^{X,Y}$ is defined on those $n$-simplices over $X \diamond Y$ that map surjectively onto $2$ by sending a triple $(\sigma \in X_n, \alpha: [n] \to [1], \tau \in Y_n)$ representing an $n$-simplex of $X \diamond Y$ to the pair $(\sigma|_{\{0, \ldots, k\}} \in X_k, \tau|_{\{k+1, \ldots, n\}} \in Y_{n-k-1})$ representing an $n$-simplex of $X \star Y$, where $k \in [n]$ is the maximal vertex in $\alpha^{-1}(0)$.

In the case of a pair of standard simplices, we can be even more explicit. Note that $X \diamond \Delta[-1] \cong X \star \Delta[-1] \cong X \cong \Delta[-1] \diamond X \cong \Delta[-1] \star X$, so it suffices to consider $n, m \geq 0$. In this case, we may describe $s^{n,m}$ as the quotient of a map $\overline{s}^{n,m}: \Delta[n] \times \Delta[1] \times \Delta[m] \to \Delta[n + 1 + m]$ defined by its order-preserving action on vertices, as described in the statement. Note this definition takes simplices related under the congruence described in Definition D.2.13 to the same simplex and thus induces a unique map $s^{n,m}: \Delta[n] \diamond \Delta[m] \to \Delta[n] \star \Delta[m]$ on the quotient simplicial set, which can easily be checked to coincide with the definition given in (D.2.16).

We now prove that the natural comparison between the fat join of simplices and the join of simplices defines a component of a marked homotopy equivalence, in the sense introduced in Definition D.1.16.

D.2.17. Proposition. For each $n, m \geq -1$, the map of augmented simplicial sets

$$s^{n,m}: \Delta[n] \diamond \Delta[m] \to \Delta[n] \star \Delta[m] \in s\mathcal{S}_{\Delta}$$

is a marked homotopy retract equivalence which is an isomorphism in the case $n = -1$ or $m = -1$.

Proof. To define a section and left homotopy inverse to $s^{n,m}$, we consider a map $\overline{t}^{n,m}: \Delta[n+1+m] \to \Delta[n] \times \Delta[1] \times \Delta[m]$ determined by its order-preserving action on vertices:

$$\overline{t}^{n,m}(i) = \begin{cases} (i, 0, 0) & \text{if } i \leq n, \\ (n, 1, i-n-1) & \text{if } i > n \end{cases}$$

and note immediately that $\overline{s}^{n,m} \circ \overline{t}^{n,m} = \text{id}$. The obverse composite $\overline{p}^{n,m} \circ \overline{s}^{n,m}$ is given by the explicit formula:

$$\overline{p}^{n,m}(i, j, k) = \begin{cases} (i, 0, 0) & \text{if } j = 0, \\ (n, 1, k) & \text{if } j = 1. \end{cases}$$

Now we may define a related order preserving endo-map $\overline{u}^{n,m}$ on $[n] \times [1] \times [m]$ by

$$\overline{u}^{n,m}(i, j, k) = \begin{cases} (i, 0, 0) & \text{if } j = 0, \\ (i, 1, k) & \text{if } j = 1. \end{cases}$$
which is of interest because in the pointwise ordering on such maps we have $\tilde{u}^{n,m} \leq \tilde{t}^{n,m} \circ \tilde{s}^{n,m}$ and $\tilde{u}^{n,m} \leq \text{id}_{[n]\times[1]\times[1]}$, representing simplicial homotopies:

$$
\Delta[n] \times \Delta[1] \times \Delta[m] \quad \Delta[n] \times \Delta[1] \times \Delta[m] \quad \Delta[n] \times \Delta[1] \times \Delta[m]
$$

$\delta^0 \quad \delta^1 \quad \delta^1 \quad \delta^0$

$\tilde{u}^{n,m} \quad \tilde{t}^{n,m} \quad \tilde{t}^{n,m} \quad \tilde{t}^{n,m}$

$\Delta[n] \times \Delta[1] \times \Delta[m] \quad \Delta[n] \times \Delta[1] \times \Delta[m] \quad \Delta[n] \times \Delta[1] \times \Delta[m] \quad \Delta[n] \times \Delta[1] \times \Delta[m]$

$\delta^0 \quad \delta^1 \quad \delta^1 \quad \delta^0$

$\tilde{h}^{n,m} \quad \tilde{k}^{n,m} \quad \tilde{k}^{n,m} \quad \text{id}_{\Delta[n]\times\Delta[1]\times\Delta[m]}$

Passing to quotients under the congruence defined in Definition D.2.13, these maps induce simplicial maps $t^{n,m}: \Delta[n] \circ \Delta[m] \to \Delta[n] \circ \Delta[m]$ and $u^{n,m}: \Delta[n] \circ \Delta[m] \to \Delta[n] \circ \Delta[m]$ so that $s^{n,m} \circ t^{n,m} = \text{id}_{\Delta[n]\circ\Delta[m]}$ and simplicial homotopies $h^{n,m}$ and $k^{n,m}$ that assemble into a diagram:

$$
\Delta[n] \circ \Delta[m] \quad \Delta[n] \circ \Delta[m] \quad \Delta[n] \circ \Delta[m]
$$

$\delta^0 \quad \delta^1 \quad \delta^1 \quad \delta^0$

$\tilde{h}^{n,m} \quad \tilde{k}^{n,m} \quad \text{id}_{\Delta[n]\circ\Delta[m]}$

$\Delta[n] \circ \Delta[m] \quad \Delta[n] \circ \Delta[m] \quad \Delta[n] \circ \Delta[m] \quad \Delta[n] \circ \Delta[m]$

$\delta^0 \quad \delta^1 \quad \delta^1 \quad \delta^0$

$\tilde{h}^{n,m} \quad \tilde{k}^{n,m} \quad \text{id}_{\Delta[n]\circ\Delta[m]}$

To see that the maps $h^{n,m}$ and $k^{n,m}$ define marked homotopies, Definition D.1.16 tells us that we must verify that for each 0-simplex $[i,j,k]$ of $\Delta[n] \circ \Delta[m]$ the 1-simplex $(i,j,k) \cdot \sigma^0, \text{id}_{[1]}$ of $(\Delta[n] \circ \Delta[m]) \times \Delta[1]$ is mapped by $h^{n,m}$ and $k^{n,m}$ to degenerate, and thus marked, simplices in $\Delta[n] \circ \Delta[m]$. We argue by cases in the index $j$. If $j = 0$, then $\tilde{u}^{n,m}(i,0,k) = (i,0,0) \sim (i,0,k) = \tilde{t}^{n,m} \circ \tilde{s}^{n,m}(i,0,k)$, so the components of both $h^{n,m}$ and $k^{n,m}$ are degenerate. If $j = 1$, then $\tilde{u}^{n,m}(1,1,k) = (i,1,k) \sim (i,1,k) = \tilde{t}^{n,m} \circ \tilde{s}^{n,m}(i,1,k)$, so again the components of both $h^{n,m}$ and $k^{n,m}$ are degenerate. Thus, $s^{n,m}$ extends to a marked homotopy retract equivalence with equivalence inverse $t^{n,m}$. □

The marked simplicial homotopy equivalence constructed in Proposition D.2.17 witnesses a pointwise weak equivalence in a suitable sense between two diagrams in $s\text{Set}_+^\Delta \times s\text{Set}_+^\Delta$ considered in Lemma D.2.14. This is the key ingredient in the proof that the canonical map of augmented simplicial sets $s^{X,Y}: X \circ Y \to X \star Y$ is also a weak equivalence in a suitable sense, but this conclusion will require an exploration of the connection between the homotopy theory of marked simplicial sets and the homotopy theory of quasi-categories. We make this connection in §D.4 and then resume this line of reasoning in §D.6.

We close this section with one final result, a marked analogue of Lemma D.2.11. The join construction of Definition D.2.6 is extended to marked simplicial sets in [124].

D.2.18. Definition (join of marked simplicial sets). The simplicial join lifts to a join bifunctor

$$s\text{Set}_+^\Delta \times s\text{Set}_+^\Delta \to s\text{Set}_+^\Delta$$

536
in which a simplex $\Delta[n] \to A \star B$, with components $\Delta[k] \to A$ and $\Delta[n-k-1] \to B$, is marked in $A \star B$ if and only if at least one of the simplices in $A$ or $B$ is marked.

D.2.19. LEMMA.

(i) The Leibniz join of a complicial horn inclusion and a boundary inclusion is isomorphic to a single complicial horn inclusion:

\[
\left(\Lambda^k[n] \hookrightarrow \Delta^k[n]\right) \star \left(\partial \Delta[m] \hookrightarrow \Delta[m]\right) \cong \Lambda^k[n+1+m] \hookrightarrow \Delta^k[n+1+m]
\]

unless $k = n$, in which case the Leibniz join $\left(\Lambda^n[n] \hookrightarrow \Delta^n[n]\right) \star \left(\partial \Delta[m] \hookrightarrow \Delta[m]\right)$ is a pushout of the complicial horn inclusion $\Delta^n[n+1+m] \hookrightarrow \Delta^n[n+1+m]$.

(ii) The Leibniz joins

\[
\left(\Lambda^k[n] \hookrightarrow \Delta^k[n]\right) \star \left(\partial \Delta[m] \hookrightarrow \Delta[m]\right) \cong \Delta^k[n+1+m]'
\]

\[
\left(\Lambda^k[n] \hookrightarrow \Delta^k[n]\right) \star \left(\partial \Delta[m] \hookrightarrow \Delta[m]\right) \cong \Delta^k[n+1+m]''
\]

unless $k = n$, in which case the Leibniz joins are instead pushout of $\Delta^k[n+1+m]' \hookrightarrow \Delta^k[n+1+m]''$, while $\left(\Delta^k[n] \hookrightarrow \Delta^k[n]\right) \star \left(\partial \Delta[m] \hookrightarrow \Delta[m]\right)$ is the identity map.

The last case of this result is generalized in Exercise D.2.iii.

PROOF. The underlying map of simplicial sets in (i) is identified in Lemma D.2.11, so it remains only to consider the markings. Similarly, in each of the three Leibniz joins considered in (ii), the underlying map of simplicial sets is a Leibniz join of a monomorphism with an identity, and is thus an identity, so it remains only to consider the markings in the resulting entire inclusion. Since a simplex in a join of marked simplicial sets is marked if and only if either of its components are, this description lends itself readily to a case analysis. We leave the details to Exercise D.2.ii or to [125, 38].

The slice construction of Definition D.2.8 also extends to marked simplicial sets. We adopt new notation for this construction because it is not always the case that the underlying simplicial set of the marked join is the slice of corresponding map of underlying simplicial sets.

D.2.20. LEMMA. For any map of marked simplicial sets $f: X \to A$, there exist marked simplicial sets $\underline{f \parallel A}$ and $A_{\parallel f}$ characterized by the universal properties

\[
\left\{ \begin{array}{c}
X \xrightarrow{f} Y \\
X \star Y \xrightarrow{f} A
\end{array} \right\} \cong \left\{ \begin{array}{c}
Y \to f \parallel A
\end{array} \right\} 
\]

and

\[
\left\{ \begin{array}{c}
Y \star X \\
Y \xrightarrow{f} A
\end{array} \right\} \cong \left\{ \begin{array}{c}
Y \to A_{\parallel f}
\end{array} \right\}.
\]

D.3. Leibniz stability of cartesian products

We now turn our attention to analogous Leibniz constructions defined with respect to the cartesian product, which in the context of marked simplicial sets is called the Gray tensor product in [125] for reasons we shall explain. To warm up, let us demonstrate the following basic result about the combinatorics of simplicial sets.

D.3.1. Lemma. For any $n, m \geq 0$, the Leibniz product of the simplex boundary inclusions

$$(\partial \Delta[n] \hookrightarrow \Delta[n]) \times (\partial \Delta[m] \hookrightarrow \Delta[m]) \cong \partial \Delta[n] \times \Delta[m] \cup_{\partial \Delta[n] \times \partial \Delta[m]} \Delta[n] \times \partial \Delta[m] \hookrightarrow \Delta[n] \times \Delta[m]$$

is a monomorphism.

Proof. Products, pushouts, and monomorphisms in $sSet$ are determined pointwise in the category of sets, so this result follows from the fact that for monomorphisms $S \hookrightarrow T$ and $U \hookrightarrow V$ of sets, the Leibniz product

$$(S \hookrightarrow T) \times (U \hookrightarrow V) \cong (S \times V \cup_{S \times U} T \times U \hookrightarrow T \times V)$$

is a monomorphism, which is clear by inspection. □

D.3.2. Remark (why “Leibniz”). The domain of the inclusion of Lemma D.3.1 defines the boundary of the prism $\partial(\Delta[n] \times \Delta[m])$ and the identification

$$\partial(\Delta[n] \times \Delta[m]) \cong \partial \Delta[n] \times \Delta[m] \cup_{\partial \Delta[n] \times \partial \Delta[m]} \Delta[n] \times \partial \Delta[m]$$

is formally similar to various identities that are commonly called “the Leibniz rule.”

In this section, we prove a number of combinatorial results along the lines of Lemma D.3.1, each of which have corollaries along the following lines:

D.3.3. Corollary.

(i) The Leibniz product of any pair of monomorphisms of simplicial sets is again a monomorphism.

(ii) The Leibniz exponential of any trivial fibration of simplicial sets with any monomorphism is again a trivial fibration.

Proof. By Lemma C.5.9 any monomorphism of simplicial sets can be built as a cell complex from the simplex boundary inclusions. By Proposition C.2.9(vi) it follows that pushout products of monomorphisms can be built as a cell complex out of pushout products of simplex boundary inclusions. Lemma D.3.1 verifies that these maps are monomorphisms, and since the monomorphisms are closed under coproduct, pushout, and sequential composition, the result of (i) follows.

For (ii), recall from Definition 1.1.24 that the trivial fibrations are characterized by the right lifting property against the monomorphisms. To see that the Leibniz exponential $\widetilde{\{i, p\}}$ of a trivial fibration $p$ with a monomorphism $i$ is a trivial fibration, it suffices to show that for any other monomorphism $j$, $j$ has the left lifting property with respect to $\widetilde{\{i, p\}}$. By Proposition C.2.9(ii) this lifting problem transposes to one between $i \times j$ and $p$, which can be solved by (i). □

D.3.4. Proposition. The category of marked simplicial sets is cartesian closed with

- cartesian product, called the Gray tensor product, giving by marking every simplex in the cartesian product of the underlying simplicial sets just when both components are marked simplices
• internal hom \(Y^X\) defined to be the simplicial set whose \(n\)-simplices \(\sigma \in Y^X\) are marked simplicial maps 
\[\sigma: X \times \Delta[n] \to Y\] 
that are marked just when \(\sigma\) extends to a marked simplicial map 
\[\begin{array}{ccc}
X \times \Delta[n] & \xrightarrow{\sigma} & Y \\
\downarrow & & \downarrow \\
X \times \Delta[n], & & \\
\end{array}\]

Proof. It’s clear from the universal property of the product and its closure that the cartesian product and internal hom must be defined in this way if these objects exist. To verify the adjunction, recall from Proposition D.1.4 that marked simplicial sets embed as a reflexive full subcategory of a category of presheaves \(\mathbf{Set}^{\Delta^{op}}\), and this embedding preserves the products and internal homs as just defined. Now we conclude that these define the functors of a two-variable adjunction on \(s\mathbf{Set}^+\) by restricting the corresponding natural isomorphisms from \(\mathbf{Set}^{\Delta^{op}}\).

The result of Lemma D.3.1 can easily be extended to the marked context. Our proof will use a simple observation that will also be deployed elsewhere.

D.3.5. Lemma. The Leibniz product of any map of marked simplicial sets with an entire inclusion is an entire inclusion.

Proof. By definition the Leibniz product of maps \(X \to Y\) and \(U \xleftarrow{e} V\) is the induced map of marked simplicial sets

\[\begin{array}{ccc}
X \times U & \xleftarrow{e} & X \times V \\
\downarrow & & \downarrow \\
Y \times U & \xleftarrow{e} & Y \times V \\
\end{array}\]

Note that the forgetful functor \(U: s\mathbf{Set}^+ \to s\mathbf{Set}\) preserves products and pushouts, and recall that a map of marked simplicial sets is entire just when the underlying map is an isomorphism. Since the product of a simplicial set with an isomorphism is an isomorphism, the maps \(X \times U \xleftarrow{e} X \times V\) and \(Y \times U \xleftarrow{e} Y \times V\) are entire. Since pushouts of isomorphisms are isomorphisms, it follows that the remaining horizontal map is also entire. Finally, since isomorphisms obey the 2-of-3 property, the Leibniz product map must also be entire.

Proof. By Corollary D.3.3, the underlying simplicial set of the Leibniz product of two regular inclusions \(A \xleftarrow{r} B\) and \(C \xleftarrow{r} D\) is the monomorphism 
\[A \times D \cup_{A \times C} B \times C \xleftarrow{r} B \times D.\]

Note, in particular, that the inclusions of the components \(A \times D\) and \(B \times C\) jointly surject onto the domain of this map. Our task is to show that any \(n\)-simplex in \(A \times D \cup_{A \times C} B \times C\) that is marked in \(B \times D\) is marked in \(A \times D \cup_{A \times C} B \times C\). We argue by cases and assume without loss of generality
that the \( n \)-simplex is in the image of the inclusion from \( B \times C \). In this case, the regularity of the map \( B \times C \hookrightarrow_r B \times D \) implies that it is marked in \( A \times D \cup_{A \times C} B \times C \) as claimed. \( \square \)

**D.3.7. Lemma.** For any \( n, m \geq 0 \), the Leibniz products 
\[
(\partial \Delta[n] \hookrightarrow_r \Delta[n]) \times (\Delta[m] \hookrightarrow_e \Delta[m]_t) \quad \text{and} \quad (\Delta[n] \hookrightarrow_e \Delta[n]_t) \times (\Delta[m] \hookrightarrow_e \Delta[m]_t)
\]
are monomorphisms of marked simplicial sets.

**Proof.** By Lemma D.3.5, both Leibniz products are entire maps of marked simplicial sets. Note that every entire map of marked simplicial sets is a monomorphism. \( \square \)

Combining Lemmas D.1.5, D.3.1, and D.3.7, we have:

**D.3.8. Corollary.**

(i) The Leibniz product of any pair of monomorphisms of marked simplicial sets is again a monomorphism.

(ii) The Leibniz exponential of any trivial fibration of marked simplicial sets with any monomorphism is again a trivial fibration. \( \square \)

Considerably harder is to show the “Leibniz stability” of the class of marked anodyne extensions with the class of marked monomorphisms. We prove a slightly more specific result that also describes the cases of “inner,” “left,” or “right” marked anodyne extensions, which restrict the inequalities \( 0 \leq k \leq n \) to \( 0 < k < n \), \( k < n \), or \( 0 < k, \) respectively.

**D.3.9. Proposition.** For \( n \geq 1 \), \( m \geq 0 \), and \( 0 < k \leq n \) each of the Leibniz products
\[
(\Lambda^k[n] \hookrightarrow_r \Delta^k[n]) \times (\partial \Delta[m] \hookrightarrow_r \Delta[m]) \quad \text{and} \quad (\Delta[n] \hookrightarrow_e \Delta[n]_t) \times (\Delta[m] \hookrightarrow_e \Delta[m]_t)
\]
is a right marked anodyne extension and is an inner marked anodyne extension if \( k < n \).

Note that, on account of the symmetry of the cartesian product—in contrast to the antisymmetry \((A \star B)^{\text{op}} \cong B^{\text{op}} \star A^{\text{op}}\) of the join—whether the horn inclusion or the simplex boundary inclusion appears on the left or right is immaterial. The proof of this result will require some special notation to describe the cartesian product of simplices.

**D.3.10. Digression (on shuffles).** By the Yoneda lemma, an \( r \)-simplex in \( \Delta[n] \) may be represented by a map \( i: \Delta[r] \rightarrow \Delta[n] \). Since \( \Delta[n] \) is the nerve of the poset \([n]\), an \( r \)-simplex may equally be represented by the ordered sequence of vertices \( i_0 \leq \cdots \leq i_r \in [n] \) appearing in its image.

By the universal property of the product, an \( r \)-simplex in \( \Delta[n] \times \Delta[m] \) is given by a pair \( i: \Delta[r] \rightarrow \Delta[n] \) and \( j: \Delta[r] \rightarrow \Delta[m] \) comprised of an \( r \)-simplex in \( \Delta[n] \) together with an \( r \)-simplex in \( \Delta[m] \). Since \( \Delta[n] \times \Delta[m] \) is the nerve of the poset \([n] \times [m] \), such simplices correspond bijectively to ordered sequences of pairs
\[
(i_{0r}, j_0) \leq (i_{1r}, j_1) \leq \cdots \leq (i_{rr}, j_r)
\]
with each \( i_s \in [n] \) and each \( j_t \in [m] \).

The non-degenerate \( n + m \)-simplices of the simplicial set \( \Delta[n] \times \Delta[m] \) are called **shuffles**. An \( n + m \)-simplex \((i, j)\) defines a shuffle just when \( i_t + j_t = t \) for all \( t \in [n + m] \). If the objects of \([n] \times [m] \) are arranged in a rectangle grid, the shuffles are those maximal-length non-degenerate paths that start from \((0, 0)\) and end with \((n, m)\), by taking steps which change exactly one coordinate at a time.
The first case of the following proof is an adaptation of an argument of Dugger and Spivak [36, A.1] to the marked context.

**Proof.** By Lemma D.3.6, the Leibniz product $(\Lambda^k[n] \hookrightarrow_r \Lambda^k[n]) \times (\partial \Delta[m] \hookrightarrow_r \Delta[m])$ is the regular inclusion

$$\Lambda^k[n] \times \Delta[m] \cup \Lambda^k[n] \times \partial \Delta[m] \hookrightarrow_r \Delta^k[n] \times \Delta[m].$$

A non-degenerate $r$-simplex (D.3.11) of $\Delta^k[n] \times \Delta[m]$ is missing from the domain of the Leibniz product inclusion just when

- its component $\{i_0, \ldots, i_r\} \supset [n]\{k\}$ and
- its component $\{j_0, \ldots, j_r\} \supset [m]$.

We will filter this inclusion as a sequence of regular inclusions

$$\Lambda^k[n] \times \Delta[m] \cup \Lambda^k[n] \times \partial \Delta[m] \hookrightarrow_r \Delta^k[n] \times \Delta[m]$$

and argue that each $Y^t \hookrightarrow Y^{t+1}$ is left or inner marked anodyne, as appropriate.

Starting from $Y^{-1} := \Lambda^k[n] \times \Delta[m] \cup \Lambda^k[n] \times \partial \Delta[m]$, we define $Y^t$ to be the smallest regular simplicial subset of $\Delta^k[n] \times \Delta[m]$ containing $Y^{t-1}$ together with every simplex (D.3.11) that contains the vertex $(k, t)$. Since every missing simplex is a face of a simplex that contains one of the vertices $(k, 0), \ldots, (k, m)$, it is clear from this description that $Y^m = \Delta^k[n] \times \Delta[m]$.

It remains only to analyze the regular inclusions $Y^{t-1} \hookrightarrow_r Y^t$, which we do by producing another filtration

$$Y^{t-1} = Y^{t,n-1} \hookrightarrow_r Y^{t,n} \hookrightarrow_r \cdots \hookrightarrow_r Y^{t,n+m} = Y^t.$$

Note that every simplex of $\Delta^k[n] \times \Delta[m]$ that contains the vertex $(k, t)$ and has dimension $n - 1$ or less is contained in $Y^{-1}$, so the simplices containing the vertex $(k, t)$ that are attached to $Y^{t-1}$ to form $Y^t$ have dimensions between $n$ and $n + m$. With this in mind, we define $Y^{l,r}$ to be the smallest regular simplicial subset of $\Delta^k[n] \times \Delta[m]$ containing $Y^{l-1,r}$ and all simplices of dimension $r$ that contain the vertex $(k, t)$. In particular, $Y^{l,n-1} = Y^{l-1}$ and $Y^{l,n+m} = Y^t$.

We now argue that each regular inclusion in this filtration is a pushout of a coproduct of complicial horn inclusions followed by complicial thinness extensions

$$\prod_{\tau \in S^{l,r}} \Lambda^{\ell_\tau}[r] \longrightarrow Y^{t,r-1}$$

$$\prod_{\tau \in S^{l,r}} \Delta^{\ell_\tau}[r] \longrightarrow Y^{t,r}$$

indexed by the sets $S^{l,r}$ of $r$-simplices containing the vertex $(k, t)$ and not already present in $Y^{l,r-1}$ and $T^{l,r} \subset S^{l,r}$ defined to be the subset of those $r$-simplices $\tau$ so that $\tau \cdot \delta^r_\tau$ is marked in $\Delta^k[n] \times \Delta[m]$. Moreover, for each $\tau \in S^{l,r}$, we will see that that $0 < \ell_\tau$ and if $k < n$ then $\ell_\tau < r$. This will show that
the Leibniz product is a right marked anodyne extension, which is an inner marked anodyne extension if $k < n$.

To see this, let $\tau \in S^{t,r}$ be the $r$-simplex

$$(i_0, j_0) \leq \cdots \leq (i_\ell, j_\ell) = (k, t) \leq \cdots \leq (i_r, j_r)$$

containing $(k, t)$ as its $\ell$-th vertex; for readability we write $\ell$ for $\ell$ going forward. Since the set $\{i_0, \ldots, i_r\} \supset [n]$ and $0 < k$ we must also have $0 < \ell$, and if $k < n$, we must also have $\ell < r$. We will argue that:

1. Each face of $\tau$ except the $\ell$th is contained in $Y^{t,r-1}$.
2. The $\ell$th face of $\tau$ is not in $Y^{t,r-1}$.
3. The $r$-simplex $\tau$ is a $r$-admissible simplex of $\Delta^k[n] \times \Delta[m]$.
4. If $\tau \cdot \delta^\ell$ is marked in $\Delta^k[n] \times \Delta[m]$ then so is $\tau \cdot \delta^{\ell-1}$ and $\tau \cdot \delta^{\ell+1}$ (in the case $\ell < r$).

Thus, the union of $\tau$ with $Y^{t,r-1}$ may be formed as a pushout of a complicial horn extension $\Delta^k[r] \xhookrightarrow{r} \Delta^k[r]$ as claimed.

For the first item, note that each codimension-one face except for $\tau \cdot \delta^\ell$ has dimension $r-1$ and contains the vertex $(k, t)$ and thus lies in $Y^{t,r-1}$ as claimed. To see that $Y^{t,r-1}$ does not also contain the face $\tau \cdot \delta^\ell$, we consider the vertex $(i_{\ell-1}, j_{\ell-1})$. If $i_{\ell-1} = k$ then by non-degeneracy, $j_{\ell-1} < t$, in which case we would have $\tau \in Y^{t-1}$, a contradiction. Thus $i_{\ell-1} < k$. Now if $i_{\ell-1} \leq k-2$, then we would have $\tau \in Y^{-1}$, again a contradiction. So it must be that $i_{\ell-1} = k-1$. Now if $j_{\ell-1} < t$, then $\tau$ would be a face of the $r+1$-dimensional simplex

$$(i_0, j_0) \leq \cdots \leq (i_{\ell-1}, j_{\ell-1}) \leq (k, t-1) \leq (i_\ell, j_\ell) = (k, t) \leq \cdots \leq (i_r, j_r)$$

which is contained in $Y^{-1}$, a contradiction. So we conclude that $(i_{\ell-1}, j_{\ell-1}) = (k-1, t)$.

From this computation we see that the vertices of $\tau \cdot \delta^\ell$ satisfy $\{i_0, \ldots, i_{\ell-1} = k-1, i_{\ell+1}, \ldots, j_r\} \supset [n] \times [k]$ and $\{i_0, \ldots, i_{\ell-1}, j_{\ell+1}, \ldots, j_r\} \supset [m]$. Thus, $\tau \cdot \delta^\ell$ is not in $Y^{-1}$. Furthermore, $\tau \cdot \delta^\ell$ was not added in along the way to $Y^{t,r-1}$, since it is not a face of a simplex containing the vertex $(k, s)$ for any $s < t$. This completes our second task.

We have shown that it is possible to attach $\tau$ to $Y^{t,r-1}$ along with its $\ell$th face by filling a suitable horn. It remains only to argue that the horn $\Delta^k[r] \xrightarrow{r} Y^{t,r-1}$ along which we are attaching $\tau$ is admissible. Since the inclusion $Y^{t,r-1} \hookrightarrow r \Delta^k[n] \times \Delta[m]$ is regular it suffices to show that each simplex containing the vertices $(i_{\ell-1}, j_{\ell-1}), (i_\ell, j_\ell)$, and $(i_{\ell+1}, j_{\ell+1})$ or just the first two of these in the case $\ell = r$ is marked in $\Delta^k[n] \times \Delta[m]$. We’ve seen above that $(i_{\ell-1}, j_{\ell-1}) = (k-1, t)$ and $(i_\ell, j_\ell) = (k, t)$.

In the case $\ell < r$, since $\tau$ is missing from $Y^{-1}$, $i_{\ell+1}$ must equal $k$ or $k+1$. But now the component in $\Delta[m]$ of this simplex is degenerate, containing the sequence $t \leq t$, while the component in $\Delta^k[n]$ is either degenerate, contains the sequence $k-1 \leq k \leq k+1$, or contains the sequence $k-1 \leq k$ in the case $\ell = r$ in which case $k = n$. Thus both components are marked simplices, which means that their product is marked in $\Delta^k[n] \times \Delta[m]$ as required.

Finally, we must argue that the simplices attached by the pushout contain all the markings present in the regular subset $Y^{t,r} \hookrightarrow r \Delta^k[n] \times \Delta[m]$. The only simplices present in $Y^{t,r}$ but not $Y^{t,r-1}$ are in dimensions $r$ and $r-1$. The newly attached $r$-simplices are all marked, so we need only concern ourselves with the $(r-1)$-simplex

$$(i_0, j_0) \leq \cdots \leq (i_{\ell-1}, j_{\ell-1}) = (k-1, t) \leq (i_{\ell+1}, j_{\ell+1}) \leq \cdots \leq (i_r, j_r)$$

arising as the $\ell$-face for each $\tau \in S^{t,r}$ when this simplex is marked in $\Delta^k[n] \times \Delta[m]$. 

452
There are two cases depending on whether \( i_{\ell+1} = k + 1 \) or \( i_{\ell+1} = k \). In the former case, the fact that this simplex is marked tells us that there is a duplication present in the sequence \( j_0 \leq \cdots \leq j_{\ell+1} \leq \cdots \leq j_r \). When we substitute \( i_{\ell} = k \) in the first sequence for \( i_{\ell-1} \) or \( i_{\ell+1} \) either the duplication remains or we now have the subsequence \( k - 1 \leq k \leq k + 1 \). Either way, this tells us that the component of the faces \( \tau \cdot \delta^{\ell-1} \) and \( \tau \cdot \delta^{\ell+1} \) is marked in \( \Delta^k[n] \). Similarly, when we substitute \( j_{\ell} = t \) for \( j_{\ell-1} = t \), the sequence is unchanged, and when we substitute for \( j_{\ell+1} \) our sequence now contains a duplication \( t \leq t \). Either way, this tells us that the component of the faces \( \tau \cdot \delta^{\ell-1} \) and \( \tau \cdot \delta^{\ell+1} \) is marked in \( \Delta^k[n] \). In conclusion, the simplex \( \tau : \Delta^{\ell}[r] \to \Delta^k[n] \times \Delta^m \) extends along \( \Delta^k[n] \hookrightarrow e \Delta^k[n] \), so we obtain the desired marking of its \( \ell \)-th face by extending along the entire inclusion \( \Delta^k[n]^\prime \hookrightarrow e \Delta^k[n]^\prime \) included in the second pushout.

In the case where \( i_{\ell+1} = k \), the sequence of vertices for \( \tau \delta^{\ell-1} \) contains \( k \leq k \) in its first component and the same sequence of vertices as \( \tau \delta^{\ell} \) in its second component. Thus, \( \tau \delta^{\ell-1} \) is marked. The sequence of vertices for \( \tau \delta^{\ell+1} \) contains \( k - 1 \leq k \leq k + 1 \) in its first component and \( t \leq t \) in its second component. Thus, \( \tau \delta^{\ell+1} \) is marked, and once more we obtain the desired marking of its \( \ell \)-th face by extending along the entire inclusion \( \Delta^k[n]^\prime \hookrightarrow e \Delta^k[n]^\prime \) included in the second pushout. This completes the proof that the first Leibniz product is a marked anodyne extension.

By Lemma D.3.5, the remaining three Leibniz products are entire inclusions, so all that is required is to verify that the additional markings present in the codomains are the results of complicial thinness extensions. We treat simultaneously the two cases involving Leibniz products

\[
(\Delta^k[n]^\prime \hookrightarrow e \Delta^k[n]^\prime) \times (A \hookrightarrow B)
\]

of a complicial horn inclusion with a marked monomorphism. The only marked simplex of \( \Delta^k[n]^\prime \) that is not marked in \( \Delta^k[n] \) is the face \( \delta^k : \Delta[n-1],_t \to \Delta^k[n]^\prime \), which implies that we have a pullback and pushout square

\[
\begin{align*}
\coprod_{\tau \in S} \Delta[n-1] & \to \Delta^k[n]^\prime \times B \cup_{\Delta^k[n]^\prime \times A} \Delta^k[n]^\prime \times A \\
\coprod_{\tau \in S} \Delta[n-1],_t & \to \Delta^k[n]^\prime \times B
\end{align*}
\]

where \( S \) is the set of marked \((n-1)\)-simplices in \( B \) that are not present or not marked in \( A \). We argue that for any marked \((n-1)\)-simplex \( \tau \in B \), the degenerate \( n \)-simplex \( \tau \sigma^{k-1} \) admits the indicated markings:

\[
\begin{align*}
\Delta[n] & \hookrightarrow \Delta^k[n]^\prime \\
\sigma^{k-1} & \downarrow \\
\Delta[n-1],_t & \to B \\
\tau & \downarrow
\end{align*}
\]

because the \( k-1 \)th and \( k \)th faces equal \( \tau \), and so are marked, and any face that contains the vertices \( k - 1 \) and \( k \) is degenerate and so is also marked; these conditions cover all of the required marked faces.
Now it is clear that the pushout square above factors through the left-hand pushout diagram

\[
\begin{array}{ccc}
\coprod_{\tau \in S} \Delta[n-1] & \xrightarrow{\delta} & \coprod_{\tau \in S} \Delta[n]' \\
\downarrow & & \downarrow \rho \\
\coprod_{\tau \in S} \Delta[n-1] & \xrightarrow{\delta^k} & \coprod_{\tau \in S} \Delta[n]'' \\
\end{array}
\]

demonstrating that the Leibniz product inclusion is a pushout of coproducts of suitable complicial thinness extensions.

The final case of

\[(\Lambda^k[n] \hookrightarrow \Lambda^k[n]) \times (\Lambda^k[m] \hookrightarrow \Lambda^k[m]) \cong \Lambda^k[n] \times \Lambda^k[m] \cup \Delta^k[n] \times \Lambda^k[m] \hookrightarrow \Delta^k[n] \times \Delta^k[m]
\]

is again an entire inclusion. Since the only simplex that is marked in \(\Delta^k[n]\) but not in \(\Delta^k[m]\) is the top-dimensional \(m\)-simplex, the only simplices that are marked in the codomain but not in the domain are \(m\)-simplices \((\tau, \text{id}) : \Delta^k[m] \hookrightarrow \Delta^k[n] \times \Delta^k[m]\) in which the image of \(\tau\) either

- contains \([n]\) or
- contains \([n]\) but not \([k]\) and is degenerate.

In particular, this Leibniz product inclusion is an identity if \(m < n\). In the case \(m = n\), there are \(m + 1\) simplices that are marked in \(\Delta^k[m] \times \Delta^k[m]\), but not in the domain, corresponding to the \(m\) \(m\)-simplices that are degenerate on the \(k\)th face of \(\Delta^k[m]\) and the top-dimensional \(m\)-simplex.

We will factor the inclusion as a finite composite of pushouts of coproducts of maps \(\Lambda^s[m+1] \rightarrow \Delta^s[m+1]\) for varying \(0 < s \leq m + 1\), where each \(s < m + 1\) if \(k < n\). This will prove that this Leibniz product is a complicial thinness extension of the appropriate kind.

We can classify the missing marked simplices in terms of their component \(\tau : \Delta^k[m] \hookrightarrow \Delta^k[n]\), which we may represent as a sequence \(i_0, \ldots, i_m\) of vertices of \([n]\) that either contains \([n]\) or contains \([n]\) \(\setminus\{k\}\) and has repetitions. We induct over a partial ordering of these simplices in decreasing order of the sum \(\sum_{t=0}^m i_t\).

For a simplex \(\tau\) with maximal vertex sum \(\sum_{t=0}^m i_t\) among those simplices that remain to be marked, let \(s\) be minimal so that \(i_s \geq k\); when \(k = n\) it is possible that all \(i_t < k = n\), which gives a second case that we will consider in a moment. Then we consider the \(m + 1\)-simplex:

\[\Delta^k[m+1] \xrightarrow{(\tau, \sigma^s, \sigma^{-1})} \Delta^k[n] \times \Delta^k[m] \hookrightarrow \Delta^k[n] \times \Delta^k[m].\]

By construction, the \(s + 1\)th face is marked in \(\Delta^k[n] \times \Delta^k[m]\), while the \(s - 1\)th face has strictly greater vertex sum, and so is marked by the inductive hypothesis. The faces containing the \(s - 1, s, \text{ and } s + 1\) vertices are all degenerate and thus marked. This proves that the face \(\tau\) can be marked by forming an extension \(\Delta^s[m+1] \rightarrow \Delta^s[m+1]\).

In the case where \(\tau\) is a simplex where all \(i_t < k = n\), then we consider the \(m + 1\)-simplex

\[\Delta^m[m+1] \xrightarrow{(\lambda, \sigma^m)} \Delta^m[n] \times \Delta^m[m].\]

\(\text{Here the vertex sum of an } m\text{-simplex } \tau \text{ is greater than the vertex sum of an } m\text{-simplex } \tau' \text{ if and only if } \tau \text{ has greater “depth” in the sense defined in [125, 68]. The induction of [125, §5.2] involves Leibniz products of inner or left horn inclusions and starts by considering simplices of lowest depth; ours involves an inner or right horn inclusion and starts by considering simplices of highest depth.}

544
where $\chi: \Delta[m + 1] \to \Delta[n]$ is the simplex spanned by the vertices $i_0, \ldots, i_m = n - 1, n$. Here the $m$th face has strictly greater sum, and so is marked by the inductive hypothesis. The faces containing the $m$th and $m + 1$th vertices have a degenerate component in $\Delta[m]$ and have a component in $\Delta[n]$ that contains the last two vertices $n - 1$ and $n$. Thus, all such simplices are marked. This proves that the face $\tau$ can be marked by forming an extension $\Delta^m[m + 1] \hookrightarrow \Delta^m[m + 1]''$. □

Proposition D.3.9 of course implies its unmarked analogue, refining the result proven in Corollary D.3.3(i):

D.3.12. COROLLARY. Let $i: A \hookrightarrow B$ and $j: K \hookrightarrow L$ be monomorphisms of simplicial sets. If either $i$ or $j$ is also anodyne (or, respectively, left-, right-, or inner-anodyne), then so is the pushout product

$$A \times L \cup_{A \times K} B \times K \xrightarrow{i \times j} B \times L$$

PROOF. The maximal marking functor $(-)^\#: \mathbf{sSet} \to \mathbf{sSet}^+$ carries (left/right/inner) horn inclusions to (left/right/inner) marked anodyne extensions, and as a left adjoint, therefore carries all (left/right/inner) anodyne extensions of simplicial sets to (left/right/inner) marked anodyne extensions. As a left and right adjoint, the maximal marking functor also preserves pushout products. Similarly, the forgetful functor $U: \mathbf{sSet}^+ \to \mathbf{sSet}$ preserves products and colimits and carries the (left/right/inner) marked anodyne extensions to the classes of anodyne extensions introduced in Definition D.2.10. Thus, this result follows immediately from the first case of Proposition D.3.9. □

Recall from Definition D.1.14 that a marked map between complicial sets is a complicial isofibration if it has the right lifting property with respect to the complicial horn inclusions and complicial thinness extensions of Definition D.1.9.

D.3.13. COROLLARY.

(i) For any quasi-category $A$ and simplicial set $X$, $A^X$ is again a quasi-category.

(ii) For any complicial set $A$ and marked simplicial set $X$, $A^X$ is again a complicial set.

(iii) For any complicial isofibration $p: E \to B$ and any monomorphism of marked simplicial sets $i: X \hookrightarrow Y$, the Leibniz exponential $[i, p]: E^Y \to E^X \times_{B^X} B^Y$ is a complicial isofibration.

PROOF. The second statement is a special case of the third statement, which follows by transposing the result of Proposition D.3.9 across the Leibniz version of the two variable adjunction of Proposition D.3.4. See Proposition C.2.9. The first statement follows similarly by applying Corollary D.3.12 in place of Proposition D.3.9. □

We would like to prove the analogous statement to Corollary D.3.13(iii) for isofibrations between quasi-categories, which requires analogous statements to Proposition D.3.9 and Corollary D.3.12 analyzing Leibniz products of monomorphisms of simplicial sets with the inclusion $1 \hookrightarrow 1$. We shall deduce this by considering the relationship between isomorphisms in quasi-categories and marked edges in complicial sets, which is the subject of the next section.

Exercises.

D.3.i. EXERCISE. The Leibniz product of a regular inclusion with a non-invertible entire inclusion will be entire but not necessarily regular. Find examples that illustrate both possibilities and state and prove a characterization of those Leibniz products of this form that are necessarily regular. Would this have simplified the proof of Proposition D.3.9?
D.4. Isomorphisms and naturally marked quasi-categories

Our aim in this section is to explain the relevance of Proposition D.3.9 to the theory of quasi-categories. In particular, this will finally enable us to complete the combinatorial work required to supply proofs of the results stated in §1.1, which we dispense with in §D.5.

The connection between the theory of complicial sets and the theory of quasi-categories is established by the two main results proven in this section, Theorems D.4.13 and D.4.19, the first of which explains that any quasi-category can be equipped with a canonically-defined “natural” marking in such a way that it defines a 1-trivial complicial set. The markings on the 1-simplices cannot be arbitrarily assigned: every marked edge must be an equivalence in a sense that we now introduce:

D.4.1. Definition. A 1-simplex $f$ in a marked simplicial set is an equivalence if there exist a pair of thin 2-simplices as displayed

\[
\begin{array}{ccc}
& x & \\
\downarrow & f & \downarrow \\
y & y & \\
\end{array}
\quad
\begin{array}{ccc}
& y & \\
\downarrow & f & \downarrow \\
x & x & \\
\end{array}
\]

Note the notion of equivalence is defined relative to the choice of markings on the 2-simplices. A very similar notion is defined for the edges of a quasi-category in Definition 1.1.13 under the name “isomorphism.”

D.4.2. Lemma. Every marked edge in a complicial set is an equivalence.

Proof. If $f$ is a marked edge in any complicial set $A$, then the $\Lambda^2[2]$-horn with 0th face $f$ and 1st face degenerate is admissible, so $f$ has a right equivalence inverse. A dual construction involving a $\Lambda^0[2]$-horn shows that $f$ has a left equivalence inverse:

\[
\begin{array}{ccc}
& x & \\
\downarrow & f & \downarrow \\
y & y & \\
\end{array}
\quad
\begin{array}{ccc}
& f & \downarrow \\
\downarrow & y & \\
x & x & \\
\end{array}
\]

Note also that the complicial thinness extensions imply further that these one-sided inverses are also marked, so they admit further inverses of their own.

This result suggests two ways to mark the edges in the nerve of a 1-category.

D.4.3. Lemma. The nerve of a 1-category defines a complicial set by marking all simplices in dimension greater than one and then either defining:

(i) the marked edges to be the identity arrows only or
(ii) the marked edges to be all isomorphisms.

Proof. Exercise D.4.i.

This motivates a definition of the canonical marking of a quasi-category, which is called the “natural marking” in [74].

D.4.4. Definition. For any quasi-category $A$, its natural marking is defined by:

- marking all simplices in dimension greater than one...
marking exactly those edges that are isomorphisms, in the sense of Definition 1.1.13, or equivalently marking all those edges that are equivalences, in the sense of Definition D.4.1.

The natural marking for quasi-categories is convenient for stating and proving an important combinatorial result due to Joyal:

D.4.5. Proposition. Any naturally marked quasi-category $A$ admits fillers for outer complicial horn inclusions for $n \geq 1$:

\[
\begin{array}{ccc}
\Lambda^0[n] & \longrightarrow & A \\
\downarrow & & \\
\Lambda^0[n] & \longrightarrow & A \\
\end{array}
\]

In the original [59], the result is stated without reference to markings as follows: a quasi-category admits fillers for special outer horns, left horns $\Lambda^0[1] \rightarrow A$ whose initial $01$-edge is mapped to an isomorphism in $A$ and right horns $\Lambda^0[1] \rightarrow A$ whose final $1n$-edge is mapped to an isomorphism in $A$.

Many proofs of Proposition D.4.5 are possible; see [36, §8] or the original [59]. We choose to use combinatorial results of Verity [125, §4.2] which we present in stages, that use an alternate (a posteriori equivalent) notion of homotopy coherent isomorphism, which a homotopy type theorist would recognize by the name “half adjoint equivalence” [121, §4.2].

D.4.6. Digression (subcomplexes of the coherent isomorphism). Recall the coherent isomorphism is the simplicial set $\mathbb{I}$ defined as the nerve of the free-living isomorphism. It has exactly two non-degenerate simplices in each dimension. If we label its vertices as “−” and “+,” then its remaining non-degenerate simplices are uniquely determined by their vertices, which are given by alternating sequences of “−” and “+” starting from either vertex. Following the notation introduced in [125, 42], we write $E^+_n, E^-_n \subset \mathbb{I}$ for the simplicial subsets generated by the $n$-simplices $- + \cdots \pm$ and $+ + \cdots \mp$ respectively. Both simplicial subsets include uniquely into both $E^+_{n+1}$ and $E^-_{n+1}$ and these inclusions can be realized as pushouts

\[
\begin{array}{ccc}
\Lambda^0[n+1] & \longrightarrow & \Delta[n+1] \\
\downarrow & & \\
E^+_n & \longrightarrow & E^+_{n+1} \\
\end{array}
\]

\[
\begin{array}{ccc}
\Lambda^{n+1}[n+1] & \longrightarrow & \Delta[n+1] \\
\downarrow & & \\
E^-_n & \longrightarrow & E^-_{n+1} \\
\end{array}
\]

as suggested by the hints given to Exercise 1.1.v.

As marked simplicial sets, we give $\mathbb{I}$ and its subcomplexes the maximal marking.

The following result gives a criterion under which an “inner complicial fibration” — a marked map that is only assumed to have the right lifting property against the inner complicial horn inclusions and inner complicial thinness extensions — whose codomain is a complicial set in fact defines a complicial isofibration in the sense of Definition D.1.14.

D.4.7. Proposition. Let $p: A \rightarrow B$ be an inner complicial fibration whose codomain $B$ is a complicial set. Then $p$ is a complicial isofibration if and only if $p$ admits lifts against the inclusions $E^+_0 \rightarrow E^+_1$ and $E^-_1 \leftarrow E^-_3$.

Proof. Clearly any complicial isofibration admits lifts against the complicial anodyne extensions $E^+_0 \leftarrow E^+_1$ and $E^-_1 \leftarrow E^-_3$. Thus, the heart of this result, and the only part that remains to be proven,
is the assertion that any inner complicial fibration whose codomain is a complicial set that admits
lifts against this pair of inclusions also admits fillers for outer complicial horn inclusions and outer
complicial thinness extensions.

We begin by arguing that an inner complicial fibration \( p : A \to B \) satisfying the conditions of
the statement also admits lifts against the dual inclusion \( E_0^- \hookrightarrow E_1^+ \). Given a lifting problem such as
presented by the maps \( a \) and \( b \) in the square below:

![Diagram](image)

there exists the dashed extension of \( b \) along \( E_1^+ \hookrightarrow E_3^- \), since this inclusion factors as a composite of
pushouts of outer complicial horn extensions and \( B \) is a complicial set. Now the inclusion \( E_0^- \hookrightarrow E_3^- \)
factors as indicated \( E_0^- \hookrightarrow E_1^- \hookrightarrow E_3^- \) and since \( p \) is assumed to lift against both maps, the dotted lift
exists as well, which restricts to define a solution to the original lifting problem.

With this result in hand, it follows that the odd dual of \( p : A \to B \) satisfies the same lifting
properties as \( p : A \to B \) does, since the odd dual of \( E_0^- \hookrightarrow E_1^- \) is \( E_0^- \hookrightarrow E_1^+ \), while the odd dual of
\( E_1^- \hookrightarrow E_3^- \) is isomorphic to itself. So it suffices to assume \( n > 1 \), in which case we have an isomorphism

\[
\Lambda^0[n] \hookrightarrow \Delta^0[n] \cong (\Lambda^0[1] \hookrightarrow \Delta^0[1]) \star (\partial \Delta[n - 2] \hookrightarrow \Delta[n - 2])
\]

by Lemma D.2.19. Writing \( m = n - 2 \) for concision, consider a lifting problem as presented by the
maps \( a \) and \( b \):

![Diagram](image)

By Lemma D.2.19 and Proposition C.2.9(vi), the map \( j \) is a complicial anodyne extension, so since \( B \) is a
complicial set, the dashed extension exists. To show that the dotted lift exists as well, we argue that the
map \( i \) is cellularly generated by the inner complicial horn extensions and the map \( E_1^- \hookrightarrow E_3^- \). To see
this, factor the map \( i \) as the composite of the three vertical maps in the middle column of the diagram.
of pushout squares

\[
\begin{array}{ccccccc}
E_1^- & \to & E_0^- \star \Delta[m] \cup E_1^- \star \partial \Delta[m] \\
\downarrow & & \downarrow \\
E_3^- & \to & \bullet & \leftarrow & E_1^- \star \partial \Delta[m] \cup E_3^- \star \emptyset \\
\downarrow & & \downarrow \\
E_0^- \star \Delta[m] \cup E_2^- \star \partial \Delta[m] & \to & \bullet & \leftarrow & E_3^- \star \partial \Delta[m] \\
\downarrow & & \downarrow \\
E_2^- \star \Delta[m] & \leftarrow & E_2^- \star \Delta[m] \cup E_3^- \star \partial \Delta[m]
\end{array}
\] (D.4.8)

The first attached cell is the map \( E_1^- \hookrightarrow E_3^- \) itself. By Digression D.4.6, \( E_1^- \hookrightarrow E_3^- \) is a right anodyne extension, so by Lemma D.2.19 the second attached cell \( (E_1^- \hookrightarrow E_3^-) \star (\emptyset \hookrightarrow \partial \Delta[m]) \) is an inner anodyne extension. Similarly \( E_0^- \hookrightarrow E_2^- \) is a right anodyne extension, so the final attached cell \( (E_0^- \hookrightarrow E_2^-) \star (\partial \Delta[m] \hookrightarrow \Delta[m]) \) is also an inner anodyne extension. Thus, \( p \) admits lifts against left complicial horn inclusions as claimed.

To see that \( p: A \to B \) also admits outer complicial thinness extensions we make use of the isomorphism

\[
(\Lambda^0[1] \hookrightarrow \Delta^0[1]) \star (\Delta[m] \hookrightarrow \Delta[m]) \cong \Delta^0[m+2] \to \Delta^0[m+2]
\]

of Lemma D.2.19, recalling that \( \Lambda^0[1] \hookrightarrow \Delta^0[1] \) is the inclusion \( E_0^- \hookrightarrow E_1^- \). So we may consider a lifting problem as presented by the maps \( a \) and \( b \):

\[
\begin{array}{cccc}
E_0^- \star \Delta[m]_f \cup E_1^- \star \Delta[m] & \overset{i}{\to} & A \\
\downarrow & & \downarrow \\
E_2^- \star \Delta[m] \cup E_3^- \star \Delta[m] & \overset{j}{\to} & E_3^- \star \Delta[m]_f \\
\downarrow & & \downarrow \\
E_1^- \star \Delta[m]_f & \overset{b}{\to} & B \\
\end{array}
\]

By Lemma D.2.19, the map \( j \) is a complicial anodyne extension, so since \( B \) is a complicial set, the dashed extension exists. To show that the dotted lift exists as well, we argue that the map \( i \) is celluarly generated by the inner complicial horn inclusions, the inner complicial thinness extensions, and the map \( E_1^- \hookrightarrow E_3^- \). To see this, factor the map \( i \) as the composite of the three vertical maps in the middle
column of the diagram of pushout squares

\[
\begin{array}{cccccc}
E_1 & \leftarrow & E_0 & \star \Delta[m]_t & \cup & E_1 & \star \Delta[m] \\
\downarrow & & \downarrow & & & \downarrow & \\
E_3 & \leftarrow & \bullet & \leftarrow & E^- \star \Delta[m] & \cup & E^- \star \emptyset \\
\leftarrow & & \leftarrow & & & \leftarrow & \\
E^0 & \star \Delta[m]_t & \cup & E^- & \star \Delta[m] & \leftarrow & E^- & \star \Delta[m] \\
\downarrow & & \downarrow & & & \downarrow & \\
E^- & \star \Delta[m]_t & \leftarrow & E^- & \star \Delta[m]_t & \cup & E^- & \star \Delta[m] \\
\end{array}
\]

The first attached cell is the map \( E_1 \hookrightarrow E_3 \) itself. By Digression D.4.6, \( E_1 \hookrightarrow E_3 \) is a right anodyne extension, so by Lemma D.2.19 the second attached cell \( (E_1 \hookrightarrow E_3) \star (\emptyset \hookrightarrow \Delta[m]) \) is an inner complicial anodyne extension. Similarly \( E_0 \hookrightarrow E_2 \) is a right anodyne extension, so the final attached cell \( (E_0 \hookrightarrow E_2) \star (\Delta[m] \hookrightarrow \Delta[m]) \) is also an inner complicial thinness extension. Thus, \( p \) admits lifts against left complicial thinness extensions as claimed. \( \square \)

Since the inclusions \( E_0 \hookrightarrow E_1 \) and \( E_1 \hookrightarrow E_3 \) are left complicial anodyne extensions, Proposition D.4.7 has the following immediate corollary.

**D.4.9. Corollary.** Let \( p : A \to B \) be an inner complicial fibration whose codomain \( B \) is a complicial set. Then if \( p \) is a left complicial fibration or a right complicial fibration, then \( p \) is a complicial isofibration. \( \square \)

**D.4.10. Remark.** Note that in the proof of Proposition D.4.7, lifts against the inclusion \( E_0 \hookrightarrow E_1 \) are only needed to construct lifts for the outer complicial horn extensions \( \Lambda^0[1] \hookrightarrow \Delta^0[1] \) and \( \Lambda^1[1] \hookrightarrow \Delta^1[1] \). Thus, even if this lifting condition is dropped, the outer complicial horn extensions in higher dimensions can still be constructed.

The argument just given supplies a proof of a special case of “special outer horn filling” that will be useful in proving the general version.

**D.4.11. Lemma.** Let \( p : A \to B \) be an inner complicial fibration whose codomain \( B \) is a complicial set. Then \( p \) admits fillers for left horns

\[
\begin{array}{ccc}
\Lambda^0[n] & \xleftarrow{a} & A \\
\downarrow & & \downarrow^p \\
\Lambda^0[n] & \xrightarrow{b} & B
\end{array}
\]

with \( n > 1 \) provided \( a \) carries the \( \{01\} \) edge of the horn \( \Lambda^0[n] \) to a degenerate simplex in \( A \).

**Proof.** Writing \( m = n - 2 \) we have an isomorphism

\[
\Lambda^0[m + 2] \hookrightarrow \Delta^0[m + 2] \cong (\Lambda^0[1] \hookrightarrow \Delta^0[1]) \star (\partial \Delta[m] \hookrightarrow \Delta[m])
\]
by Lemma D.2.19, so once more we are asked to consider a lifting problem as presented by the maps $a$ and $b$:

$$
\begin{align*}
E_0 \star \Delta[m] \cup E_1 \star \partial \Delta[m] & \xrightarrow{a} A \\
E_1 \star \Delta[m] & \xrightarrow{k} E_0 \star \Delta[m] \cup E_1 \star \partial \Delta[m] \cup E_3 \\
E_2 \star \Delta[m] \cup E_3 \star \partial \Delta[m] & \xrightarrow{\ell} E_3 \star \Delta[m] \\
E_1 \star \Delta[m] & \xrightarrow{j} B
\end{align*}
$$

The map $j$ is a complicial anodyne extension, so since $B$ is a complicial set, the lower dashed extension exists, and we are left to solve a lifting problem between the map $i$ and the map $p$. To do so, we factor the map $i$ as a composite of the three middle vertical morphisms displayed in (D.4.8) and let $k$ denote the first of these morphisms while $\ell$ denotes the composite of the second two. We next solve the lifting problem between $k$ and $p$ by defining the image of the attached $E_3$ to be a degenerate 3-simplex; note that $k$ is constructed by attaching this $E_3$ to the $E_1$ that corresponds to the initial edge of the horn $\Lambda^0[m+2]$, which $a$ maps to a degenerate edge.

Now to construct the dotted lift, it remains only to solve the lifting problem between $\ell$ and $p$, and the diagram (D.4.8) reveals that this can be done, as it expresses the map $\ell$ as the composite of pushouts of inner complicial horn inclusions. □

D.4.12. COROLLARY. A marked simplicial set $A$ that admits fillers for inner complicial horn extensions and inner complicial thinness extensions is a complicial set if and only if it admits extensions along the map $\Delta[1]^\# \hookrightarrow \text{sk}_2 \mathbb{I}^\#$.

PROOF. Applying Proposition D.4.7 to the inner complicial fibration $A \to 1$, to conclude that $A$ is a complicial set, we need only construct extensions along the maps $E_0 \hookrightarrow E_1$ and $E_1 \hookrightarrow E_3$. The former is automatic, since $E_0 \hookrightarrow E_1$ is isomorphic to $\Delta[0] \hookrightarrow \Delta[1]^\#$, which admits a retraction, so to complete our proof we will show that if $A$ admits extensions along the map $\Delta[1]^\# \hookrightarrow \text{sk}_2 \mathbb{I}^\#$ as well as fillers for inner complicial horns, then $A$ admits extensions along the map $E_1 \hookrightarrow E_3$.

The domain map $\Delta[1]^\# \cong E_1 \to A$ defines a marked 1-simplex $f \colon x \to y$ in $A$, which by hypothesis we may extend to a map $\text{sk}_2 \mathbb{I}^\# \to A$, which specifies marked 2-simplices

$$
\begin{align*}
\begin{array}{ccc}
x & \xrightarrow{\alpha} & x \\
\downarrow\alpha' & \downarrow & \downarrow\alpha' \\
y & \xrightarrow{f^{-1}} & y
\end{array}
\end{align*}
$$

It won't necessarily be the case that the pair of 2-simplices $\alpha$ and $\alpha'$ form the two non-degenerate faces of a map $E_3 \to A$ but we will construct a replacement $\beta$ of $\alpha'$ so that $\alpha$ and $\beta$ form the non-degenerate simplices of $E_3 \to A$. The 3-simplex $E_3$ will be constructed as the 2nd face of the filler to a horn $\Lambda^2[4] \to A$ that we now construct. As orientation for the construction given below, we first summarize the end result:

- the 0th, 2nd, and 3rd vertices will be $x$, while the 1st and 4th vertex will be $y$;
• all of the edges will be either \( \text{id}_x, \text{id}_y, f, \) or \( f^{-1} \), with the positioning of these determined uniquely by the vertices;
• the faces \( \{0, 1, 2\} \) and \( \{0, 1, 3\} \) are \( \alpha \), while the face \( \{1, 2, 4\} \) is \( \alpha' \);
• the faces \( \{0, 2, 3\}, \{0, 1, 4\}, \{0, 3, 4\}, \) and \( \{1, 2, 3\} \) are degenerate; and
• the missing faces \( \{0, 2, 4\} \) called \( \gamma \), \( \{2, 3, 4\} \) called \( \tilde{\gamma} \), and \( \{1, 3, 4\} \) called \( \beta \) will be filled in in this order, with the desired 3-simplex \( E_3 \) appearing as the 2nd face of the horn.

\[
\begin{array}{c}
x \rightarrow f \rightarrow y \rightarrow f^{-1} \rightarrow x \rightarrow f \rightarrow y \\
\alpha \quad \beta \\
\gamma \quad \tilde{\gamma}
\end{array}
\]

The 4th face is \( \alpha \sigma^2 \). The 3rd face is constructed by filling the horn \( \Lambda^1[3] \rightarrow A \) depicted below

\[
\begin{array}{c}
f \quad y \quad \alpha' \\
\alpha \\
\gamma \\
f^{-1} \quad f
\end{array}
\]

in which the back face is degenerate. By a complicial thinness extension, the face \( \gamma \) defined by filling this horn is marked. Next, the 1st face is constructed by filling a \( \Lambda^0[3] \hookrightarrow \Delta^0[3] \) whose 2nd face is \( \gamma \) and 1st and 3rd faces are degenerate, as permitted by Lemma D.4.11.

\[
\begin{array}{c}
x \quad f \quad y \\
\gamma \\
\tilde{\gamma}
\end{array}
\]

This produces another marked 3-simplex \( \tilde{\gamma} \) defined by filling this horn. The 0th face is constructed by filling the horn \( \Lambda^1[3] \rightarrow A \) depicted below

\[
\begin{array}{c}
f^{-1} \quad \gamma \\
\gamma \\
\tilde{\gamma}
\end{array}
\]

in which the unlabeled front face is degenerate and the unlabeled back face is \( \alpha' \). The face defined by filling this horn is the replacement 2-simplex \( \beta \). These four 3-simplices define a map \( \Lambda^2[4] \rightarrow A \)
whose filler defines a 2-simplex face as depicted below:

\[
\begin{array}{ccc}
\times & \downarrow \alpha & \beta \\
\downarrow f & \downarrow f^{-1} & \downarrow f \\
\times & \times & \times \\
\end{array}
\]

in which both the back and bottom faces are degenerate. This defines the required extension \( E_3^+ \rightarrow A \).

With Corollary D.4.12 in hand, we can now prove Joyal’s special outer horn filling result.

**Proof of Proposition D.4.5.** Let \( A \) be a naturally marked quasi-category. We must show that the unique map \( !: A \rightarrow \mathbb{1} \) satisfies the hypotheses of Corollary D.4.12. For the inner complicial horn extensions, all of the non-degenerate marked simplices are in dimension two and higher, so \( A \) admits fillers for these as well, simply because quasi-categories are simplicial sets that admit fillers for all inner horns. Since the composite of a pair of isomorphisms in a quasi-category is again an isomorphism, \( A \) admits extensions along \( \Delta^1[2]' \hookrightarrow \Delta^1[2]'' \). The remaining complicial thinness extensions of (D.1.11) are entire inclusions that differ only in markings of simplices in dimension at least two; since all such simplices are thin in the natural marking, \( A \) admits these extensions as well.

To conclude, we need only argue that \( A \) admits extensions of the form

\[
\begin{array}{ccc}
\Delta[1] & \overset{f}{\rightarrow} & A \\
\downarrow \text{sk}_2 \mathbb{1}^\sharp & & \\
\end{array}
\]

Since \( A \) is naturally marked, the attaching map \( f: x \rightarrow y \) defines an isomorphism in \( A \). By Definition 1.1.13, this means there exist 2-simplices

\[
\begin{array}{ccc}
f & y & f^{-1} \\
\alpha & \times & \alpha' \\
\times & f & \times \\
\end{array}
\]

which provide the data of the required extension \( \text{sk}_2 \mathbb{1}^\sharp \rightarrow A \). □

This proves the hard direction of the following characterization of quasi-categories as complicial sets:

**Theorem.** The natural marking of a quasi-category is a complicial set and indeed is the maximal marking that turns a quasi-category into a complicial set. Conversely, the underlying simplicial set of any complicial set with all simplices above dimension one marked is a quasi-category.

**Proof.** In the proof of Proposition D.4.5, we have shown that the natural marking of a quasi-category \( A \) defines a complicial set: the inner extensions are straightforward, while Proposition D.4.5 proves that \( A \) admits the outer complicial horn and thinness extensions of (D.1.10) and (D.1.11). By Lemma D.4.2, it is not possible to mark any additional edges in \( A \) and retain the property of being a complicial set.
The converse is elementary, and left to the reader in Exercise D.1.iii.

We now give a few sample applications of Theorem D.4.13, revisiting some results that were proven in §1.1 using Proposition D.4.5. For instance:

D.4.14. COROLLARY. A quasi-category \( A \) is a Kan complex if and only if its homotopy category is a groupoid.

PROOF. It’s clear that the homotopy category of a Kan complex is a groupoid, so we focus our attention on the converse. By Theorem D.4.13, a quasi-category may be regarded as a complicial set, with every simplex above dimension 1 marked, and where the marked edges are exactly the isomorphisms defined to be those 1-simplices that represent isomorphisms in the homotopy category. If the homotopy category of \( A \) is a groupoid, then this tells us that \( A \) is maximally marked, and Exercise D.1.ii observes that a maximally marked complicial set defines a Kan complex.

For our next result, we revisit Corollary 1.1.16 and eliminate the reference to the maximal Kan complex spanned by the isomorphisms in a quasi-category — the existence of which follows from special outer horn lifting — from the proof given there.

D.4.15. COROLLARY. An arrow \( f \) in a quasi-category \( A \) is an isomorphism if and only if it extends to a homotopy coherent isomorphism

\[
\begin{array}{c}
2 \xrightarrow{f} A \\
\downarrow \quad \ x
\end{array}
\]

PROOF. When the quasi-category \( A \) is regarded as a naturally marked complicial set, the isomorphism \( f \) defines a marked map \( f : 2^\# \rightarrow A \). By Lemma D.1.13, the injection \( 2^\# \hookrightarrow I^\# \) is a marked anodyne extension, and thus a lift

\[
\begin{array}{c}
2^\# \xrightarrow{f} A \\
\downarrow \\
I^\#
\end{array}
\]

exists. Forgetting markings, this proves that every isomorphism in \( A \) extends to a “homotopy coherent isomorphism.” The converse is obvious from Definition 1.1.13.

D.4.16. LEMMA. If \( A \) is a naturally marked quasi-category and \( X \) is a minimally marked simplicial set, then \( A^X \) is a naturally marked quasi-category.

PROOF. By Proposition D.3.4, \( n \)-simplices in \( A^X \) correspond to maps \( X \times \Delta[n] \rightarrow A \). Since \( X \) is minimally marked, it follows that the underlying simplicial set of \( A^X \) coincides with the exponential of the underlying simplicial sets and hence, by Corollary D.3.13(i) defines a quasi-category.

To see that every simplex of dimension greater than one is marked in \( A^X \) consider an extension problem

\[
\begin{array}{c}
X \times \Delta[n] \rightarrow A \\
\downarrow \\
X \times \Delta[n]_r
\end{array}
\]
for $n > 1$. By Proposition D.3.4, the only simplices that are marked in $X \times \Delta[n]$ but not in $X \times \Delta[n]$ are $n$-simplices, and since all $n$-simplices in $A$ are marked, it is clear that the desired extension exists.

By Corollary D.3.13(ii), $A^X$ is a complicial set, so by Lemma D.4.2 every marked edge in $A^X$ is an isomorphism. It remains only to show that every isomorphism $f: \Delta[1] \to A^X$ in the quasi-category $A^X$ is marked, admitting an extension as indicated below-right:

By Proposition D.3.4, the only simplices that are marked in $X \times \Delta[1]$ but not in $X \times \Delta[1]$ are 1-simplices whose component in $X$ is degenerate and whose component in $\Delta[1]$ is the non-degenerate 1-simplex, as indicated by the square above-left that is both a pullback and a pushout. The images of such simplices in $A$ define the “components” of $f$, as indicated by the top composite above.

If $f$ is an isomorphism in $A^X$ then each of its components $f_x$, the image of $f$ under the evaluation function $ev_x: A^X \to A$, are clearly also isomorphisms, which is the case if and only if each $f_x$ is marked in $A$. These components $f_x$ are marked in $A$ if and only if the dotted lift exists, and by the universal property of the pushout, this is equivalent to the existence of the dashed lift, as required. $\Box$

As a consequence of Lemma D.4.16, we can show:

D.4.18. **Corollary.** For any quasi-category $A$ and simplicial set $X$, an edge in $A^X$ is an isomorphism if and only if each of its components in $A$, indexed by the vertices of $X$, are isomorphisms.

**Proof.** Regarding $A$ as a naturally marked quasi-category and $X$ as a minimally marked simplicial set, by Lemma D.4.16 a 1-simplex in $A^X$ is marked if and only if it defines an isomorphism in the quasi-category $A^X$. So the statement asserts that a 1-simplex is marked in $A^X$ if and only if its components are marked in $A$. By the definition, given in Proposition D.3.4, of the markings in the exponential, a 1-simplex $f: \Delta[1] \to A^X$ is marked if and only if the dashed extension of (D.4.17) exists. By the argument given there, this is equivalent to the existence of the dotted extensions, which say exactly that each component $f_x$ is marked in $A$. $\Box$

A similar argument to the one used to prove Proposition D.4.5 that also employs the conclusion of that result, allow us to extend the special outer horn lifting property to isofibrations between naturally marked quasi-categories:

D.4.19. **Theorem.** An isofibration between naturally marked quasi-categories admits fillers for outer complicial horn inclusions for $n \geq 1$:

\[
\begin{array}{c}
\Lambda^0[n] \longrightarrow A \\
\Delta^0[n] \longrightarrow B
\end{array}
\]

\[
\begin{array}{c}
\Lambda^n[n] \longrightarrow A \\
\Delta^n[n] \longrightarrow B
\end{array}
\]
and an inner fibration between naturally marked quasi-categories admits fillers for outer complicial horn inclusions for \( n \geq 2 \). Consequently, an isofibration between naturally marked quasi-categories is a complicial isofibration.

**Proof.** By Theorem D.4.13, the codomain \( B \) is a complicial set, so to apply Proposition D.4.7 we must argue that an isofibration between naturally marked quasi-categories has the right lifting property against the inner complicial horn extensions, inner complicial thinness extensions, and the two maps \( E_0^\sim \hookrightarrow E_1^\sim \) and \( E_1^\sim \hookrightarrow E_3^\sim \). By Remark D.4.10, the first of these maps is only needed to construct the outer complicial horn inclusions for \( n = 1 \), so the proof given below will establish fillers for the complicial horn inclusions in dimension \( n \geq 2 \) under the weaker hypothesis where \( A \to B \) is only assumed to be an inner fibration. We'll concentrate on the case where \( A \to B \) is an isofibration henceforth.

The inner complicial horn and thinness extensions are straightforward, as in the proof of Proposition D.4.5. To construct a lift

\[
\begin{array}{c}
E_0^\sim \\
\downarrow \\
E_1^\sim \\
\downarrow \\
\mathbb{I}
\end{array} \to \begin{array}{c}
A \\
p \\
B \\
\end{array}
\]

we use Lemma D.1.13, recalled as Corollary D.4.15, to extend the codomain to a homotopy coherent isomorphism and then solve the composite lifting problem.

The construction of the lift against \( E_1^\sim \hookrightarrow E_3^\sim \) is considerably more laborious. To begin, we argue that since \( A \) and \( B \) are complicial sets and \( p \) is an inner complicial fibration, then \( p \) admits lifts against the complicial horn inclusion \( \Lambda^0[2] \to \Delta^0[2] \). To see this, we identify the codomain \( \Delta^0[2] \) with the second face of the 3-simplex \( E_2^\sim \star \Delta[0] \) and consider the lifting problem presented by the exterior diagram

\[
\begin{array}{c}
\Lambda^0[2] \\
\downarrow \\
\Delta^0[2]
\end{array} \xleftarrow{\circled{i}013} \begin{array}{c}
E_0^\sim \star \Delta[0] \cup E_2^\sim \star \emptyset \\
\downarrow \\
\bullet
\end{array} \xrightarrow{\delta^2} \begin{array}{c}
E_2^\sim \star \Delta[0] \\
r \\
\delta \\
\downarrow \\
\mathbb{I}
\end{array} \xrightarrow{\circled{j} \circ \circled{p} \circ \circled{k}} \begin{array}{c}
\Delta^0[2] \\
\downarrow \\
\bullet \\
\downarrow \\
B
\end{array} \xrightarrow{\circled{b} \circ \circled{a}} \begin{array}{c}
A \\
p \\
B
\end{array}
\]

The inclusion \( \circled{i}013 \) is complicially anodyne, so the top dashed extension exists since \( A \) is a complicial set by Theorem D.4.13. This induces the dotted map by the universal property of the pushout. Since the map \( j \) is also complicially anodyne, the bottom dashed extension exists since \( B \) is a complicial set by Theorem D.4.13. These dashed maps define a new lifting problem between the composite map \( k \) and \( p \) and since \( k \) is an inner complicial anodyne extension, the dotted lift exists, solving the original lifting problem.
Now we can use the fact that $p$ admits lifts along $\Lambda^0[2] \hookrightarrow \Delta^0[2]$ to construct lifts along the horizontal composite map

\[
\begin{array}{ccc}
E_1^+ & \xrightarrow{f} & E_1^- \\
\downarrow & & \downarrow \\
E_2^- & \xleftarrow{\tau} & E_2^+ \\
\end{array}
\]

since Digression D.4.6 reveals that both maps $E_1^+ \hookrightarrow E_2^+$ are pushouts of $\Lambda^0[2] \hookrightarrow \Delta^0[2]$. Lifts against the composite $E_1^- \hookrightarrow E_2^+ \cup E_2^-$ have the effect of giving the data of a right inverse and also a right inverse to the right inverse to an isomorphism in $A$, lifting the corresponding data in $B$. To solve a lifting problem

\[
\begin{array}{ccc}
E_1^- & \xrightarrow{\alpha} & E_2^- \\
\downarrow & & \downarrow \\
E_3^- & \xleftarrow{\tau \sigma^2} & E_3^+ \\
\end{array}
\]

we first construct the outer lift. The lift defines a pair of 2-simplices

\[
\begin{array}{ccc}
E_1^- & \xrightarrow{f} & A \\
\downarrow & & \downarrow \\
E_2^+ \cup E_2^- & \xleftarrow{(\alpha,\alpha')} & E_3^- \\
\end{array}
\]

in $A$.

We’ll now extend the data of the lifted $E_2^+ \cup E_2^- \to A$ to construct a map $E_3^- \to A$ lifting $E_3^- \to B$ using a mild modification of the construction in the proof of Corollary D.4.12.

As above, we’ll define a complicial inner horn extension

\[
\begin{array}{ccc}
\Lambda^2[4] & \xrightarrow{\alpha \sigma^2} & A \\
\uparrow & & \downarrow \\
\Lambda^2[4] & \xleftarrow{\tau \sigma^2} & B \\
\end{array}
\]

so that the lift of the 2nd face defines the simplex $E_3^- \to A$ that we seek. It remains only to define an appropriate horn $\Lambda^2[4] \to A$ over $\tau \sigma^2: \Lambda^2[4] \to B$. The 4th face is $\alpha \sigma^2$. The 3rd face is constructed by lifting along a horn $\Lambda^1[3] \leftrightarrow \Delta^1[3]$ whose 3rd face is $\alpha$, whose 0th face is $\alpha'$, and whose 2nd face is degenerate. Writing $\gamma$ for the face defined by filling this horn, the 1st face is constructed by filling a $\Lambda^0[3] \leftrightarrow \Delta^0[3]$ whose 2nd face is $\gamma$ and 1st and 3rd faces are degenerate; the argument required to justify this, as permitted by Lemma D.4.11. The 0th face is constructed by filling the horn $\Lambda^1[3] \to \Delta^1[3]$ whose faces have all already been described. The face defined by filling this horn is the replacement 2-simplex $\beta$ which witnesses that $f$ is a right inverse to its right inverse $f^{-1}$. These four
3-simplices define a map $\Lambda^2[4] \to A$ over $\tau \sigma^2$ whose filler defines a 2-simplex face as depicted below:

![Diagram of 2-simplex face](attachment:diagram.png)

in which both the back and bottom faces are degenerate. This defines the required lift along $E_1' \hookrightarrow E_3$. Now Proposition D.4.7 completes the proof that isofibrations lift against outer complicial horn inclusions.

It follows that an isofibration between naturally marked quasi-categories is a complicial isofibration: we've demonstrated that it has the required lifting property against the complicial horn inclusions. By Exercise D.1.v, the fact that $A$ is a complicial set suffices to show that $p : A \to B$ also lifts against the complicial thinness extensions. □

Theorems D.4.13 and D.4.19 permit the use of complicial techniques to solve lifting problems involving isofibrations between quasi-categories. The results of this section suggest that these techniques are particularly fruitful when isomorphisms are involved. We conclude this section by developing a few specific applications of this principle.

To that end we consider a pair of cosimplicial marked simplicial sets $\Delta[\bullet]^# \hookrightarrow \square[\bullet]^#$ in $(sSet^+)^\Delta$ between Reedy monomorphic cosimplicial objects that is moreover a pointwise weak equivalence.

**D.4.20. Lemma.** The natural inclusion $\Delta[\bullet]^# \hookrightarrow \square[\bullet]^#$ is a Reedy monomorphism in $(sSet^+)^\Delta$ between Reedy monomorphic cosimplicial objects and the natural inclusion is a Reedy monomorphism.

**Proof.** The first half of the statement follows from a general principle: any pointwise monomorphism between “unaugmentable” cosimplicial objects is a Reedy monomorphism between Reedy monomorphic cosimplicial objects, where a cosimplicial object $X^\bullet$ is unaugmentable if the equalizer of the face maps $\delta^0, \delta^1 : X^0 \to X^1$ is empty [98, 14.3.8]. The idea is that in the presence of this condition, any simplex in $X^\bullet$ is uniquely expressible as $\alpha \cdot x$, where $\alpha \in \Delta$ is a monomorphism and $x \in X^\bullet$ is not in the image of any monomorphism. The proof of this relies on the observation that nearly every monomorphism in $\Delta$ is uniquely determined by its set of left-inverses, the only exceptions being $\delta^0, \delta^1 : [0] \to [1]$; hence the “unaugmentable” condition. From this definition it is clear that both $\Delta[\bullet]^#$ and $\square[\bullet]^#$ are unaugmentable, so we conclude that these simplicial objects are Reedy monomorphic and the natural inclusion is a Reedy monomorphism.

Finally to prove that $\Delta[n]^# \to \square[n]^#$ is a pointwise weak equivalence, we appeal to the 2-of-3 property and argue that both $\Delta[n]^#$ and $\square[n]^#$ are contractible in the sense of being marked homotopy equivalent to $\mathbb{1} \in sSet^+$. The inverse homotopy equivalences are given by $0 : \mathbb{1} \to \Delta[n]^#$ and $0 : \mathbb{1} \to \square[n]^#$ and the marked homotopies $\Delta[n]^# \times \Delta[1]^# \to \Delta[n]^#$ and $\square[n]^# \times \Delta[1]^# \to \square[n]^#$ are both defined by the map on objects $(i, 0) \leftrightarrow 0$ and $(i, 1) \leftrightarrow i$. □
Our intent is to use the simplicial objects $\Delta[\bullet]^\#$ and $\mathbb{I}[\bullet]^\#$ to “freely invert” the simplices of a simplicial set $K$. To see how this works, consider also the cosimplicial object $\Delta[\bullet] \in s\Delta^\mathbb{A}$ defined by the Yoneda embedding. By the Yoneda lemma, the weighted colimit $\text{colim}_K \Delta[\bullet] \cong K$ recovers the original simplicial set $K$. Similarly, since the maximal marking functor $(-)^\# : s\Delta \to s\Delta^+$ is a left adjoint, the weighted colimit $\text{colim}_K \Delta[\bullet]^\# \cong K^\#$ equips the simplicial set $K$ with the maximal marking. Finally, we define $\tilde{K}^\# := \text{colim}_K \mathbb{I}[\bullet]^\#$ using the weighted colimit bifunctor. The idea of this functor is that it replaces each $n$-simplex of $K$ by $\mathbb{I}[n]^\#$, a “homotopy coherent composite of $n$-isomorphisms.” As the notation suggests, $\tilde{K}^\#$ is also maximally marked.

D.4.21. PROPOSITION. For any simplicial set $K$, the natural map $K^\# \to \tilde{K}^\#$ is a trivial cofibration of marked simplicial sets.

PROOF. Any simplicial set $K$ is Reedy monomorphic when considered as an object of $s\Delta^\mathbb{A}$. Hence, by Corollary C.5.17, the weighted colimit functor

$$\text{colim}_K - : (s\Delta^+)^\mathbb{A} \to s\Delta^+$$

is left Quillen with respect to the Reedy model structure on $(s\Delta^+)^\mathbb{A}$. Lemmas C.5.13 and D.4.20 prove that $\Delta[\bullet]^\# \hookrightarrow \mathbb{I}[\bullet]^\#$ is a Reedy trivial cofibration, so it follows that $K^\# \to \tilde{K}^\#$ is a trivial cofibration as claimed.

We refer to the functor $(\tilde{-}) : s\Delta \to s\Delta$ defined by applying $\text{colim}_- \mathbb{I}[\bullet]^\#$ and forgetting the markings as the “free-inversion functor.” Proposition D.4.21 has the following consequence:

D.4.22. COROLLARY. Any diagram $K \to A$ in a quasi-category $A$ whose edges are sent to isomorphisms extends to a diagram indexed by the free inversion of $K$. More generally, if $K \to A$ sends the edges of $K$ to isomorphisms of $A$, and $p : A \to B$ is an isofibration between quasi-categories, then any lifting problem

$$
\begin{array}{ccc}
K & \longrightarrow & A \\
\downarrow & & \downarrow p \\
\tilde{K} & \longrightarrow & B
\end{array}
$$

has a solution

PROOF. The hypothesis is that our given diagram extends to a map $K^\# \to A^\#$ of marked simplicial sets. By Theorem D.4.13, the natural marking of $A$ defines a complicial set and by Theorem D.4.19 $p : A^\# \to B^\#$ is a complicial isofibration, so Proposition D.4.21 implies that the lift

$$
\begin{array}{ccc}
K^\# & \longrightarrow & A^\# \\
\downarrow & & \downarrow p \\
\tilde{K}^\# & \longrightarrow & B^\#
\end{array}
$$

exists.

D.4.23. EXAMPLE. Proposition D.4.21 can be applied to the anodyne extension $\Lambda^1[2] \hookrightarrow \Delta[2]$ to prove that composites of homotopy coherent isomorphisms can be lifted along isofibrations of quasi-categories. By definition $\Delta[2] \cong \mathbb{I}[2]$, the contractible groupoid on three vertices $0$, $1$, and $2$, so we adopt similar notation $\Lambda^1[2] =: \Lambda^1[\mathbb{I}[2]]$ for the freely-inverted horn. Since $\Lambda^1[2]$ is built by gluing
two 1-simplices along a common vertex and the free inversion functor preserves colimits, we see that \( \Lambda^1[\mathbb{I}[2]] \) is the union of two homotopy coherent isomorphisms between 0 and 1 and between 1 and 2. Giving these simplicial sets their maximal markings, it follows from the 2-of-3 property applied to the square

\[
\begin{array}{ccc}
\Lambda^1[2]\# & \longrightarrow & \Lambda^1[\mathbb{I}[2]]\# \\
\downarrow & & \downarrow \\
\Delta[2]\# & \longrightarrow & \mathbb{I}[2]\#
\end{array}
\]

that the inclusion \( \Lambda^1[\mathbb{I}[2]]\# \hookrightarrow \mathbb{I}[2]\# \) is a trivial cofibration of marked simplicial sets. Applying Theorem D.4.19, we conclude that composites of homotopy coherent isomorphisms can be lifted along isofibrations between quasi-categories

\[
\Lambda^1[\mathbb{I}[2]] \longrightarrow A \\
\downarrow \\
\mathbb{I}[2] \longrightarrow B
\]

A similar example is left as Exercise D.4.ii. In fact, Joyal proves that \( \tilde{\mathcal{F}}(\cdot) : s	ext{Set} \rightarrow s	ext{Set} \) defines a left Quillen functor from Quillen's model structure for Kan complexes to Joyal's model structure for quasi-categories, whose right adjoint is the functor that sends a simplicial set \( X \) to the simplicial set whose \( n \)-simplices are maps \( \mathbb{I}[n] \rightarrow X \). His proof, which is replicated in [98, 17.6.1], makes use of a lemma that is also of interest.

D.4.24. **Lemma.** For any simplicial set \( K \), the natural inclusion \( K \hookrightarrow \tilde{K} \) is an anodyne extension.

**Proof.** This follows from Proposition D.4.21 and the fact that the functor \( s	ext{Set}^+ \rightarrow s	ext{Set} \) that forgets the markings carries marked anodyne extensions to anodyne extensions but a direct proof is also possible. To see that \( K \hookrightarrow \tilde{K} \) is an anodyne extension, consider a Kan fibration between Kan complexes \( p : A \rightarrow B \). By Corollary D.4.22 a lift

\[
\begin{array}{c}
K \\
\downarrow \\
\tilde{K}
\end{array} \xrightarrow{\exists} 
\begin{array}{c}
A \\
p \\
B
\end{array}
\]

exists from which we conclude that \( K \hookrightarrow \tilde{K} \) is an anodyne extension. \( \square \)

D.4.25. **Proposition.** The free inversion functor and its left adjoint defines a Quillen adjunction from Quillen's model structure for Kan complexes to Joyal's model structure for quasi-categories.

**Proof.** Lemma D.4.20 proves that the functor \( \mathbb{I}[\bullet]\# \) is Reedy monomorphic in \( (s	ext{Set}^+)^\Delta \). Hence, by Theorem C.5.15, the weighted colimit functor

\[
\text{colim}_\mathbb{I}[\bullet]\# : s\text{Set} \cong \text{Set}^{\Delta^{op}} \rightarrow s	ext{Set}^+
\]

carries Reedy monomorphisms to monomorphisms. Since the Reedy monomorphisms in \( \text{Set}^{\Delta^{op}} \) are just the monomorphisms in \( s\text{Set} \), in this way we see that the left adjoint \( \tilde{\cdot} : s\text{Set} \rightarrow s\text{Set} \) preserves monomorphisms.
It remains to argue that \((\sim)\) carries weak equivalences in the Quillen model structure to weak equivalences in the Joyal model structure. If \(K \sim L\) is a weak equivalence in the Quillen model structure then by the 2-of-3 property applied to the square

\[
\begin{array}{ccc}
K & \sim & L \\
\downarrow & & \downarrow \\
\tilde{K} & \sim & \tilde{L}
\end{array}
\]

the map \(\tilde{K} \sim \tilde{L}\) is as well. By construction of \(\tilde{K}\) and \(\tilde{L}\), their homotopy categories of Definition 1.1.10 are groupoids. If we fibrantly replace each object in the Joyal model structure, we obtain quasi-categories \(\tilde{K}^+\) and \(\tilde{L}^+\) which are weakly equivalent in the Joyal model structure to \(\tilde{K}\) and \(\tilde{L}\) and whose homotopy categories are thus also groupoids. In particular, by Corollary D.4.14, \(\tilde{K}^+\) and \(\tilde{L}^+\) are Kan complexes. This gives us a commutative diagram

\[
\begin{array}{ccc}
\tilde{K} & \longrightarrow & \tilde{L} \\
\downarrow & & \downarrow \\
\tilde{K}^+ & \longrightarrow & \tilde{L}^+
\end{array}
\]

in which the vertical maps are weak equivalences in the Joyal model structure, and hence also the Quillen model structure. Since the top horizontal map is also a weak equivalence is the Quillen model structure, it follows from the 2-of-3 property that \(\tilde{K}^+ \sim \tilde{L}^+\) is as well, but any weak homotopy equivalence between Kan complexes is also an equivalence of quasi-categories. By the 2-of-3 property again, we conclude that \(\tilde{K} \sim \tilde{L}\) is a weak equivalence in the Joyal model structure, as desired. \(\square\)

Exercises.

D.4.ii. Exercise. Extend the result of Example D.4.23 to show that the maximally marked “\(\Lambda^1[3]\)-horn of homotopy coherent isomorphisms” \(\Lambda^1[\mathbb{I}[3]] \hookrightarrow \mathbb{I}[3]\), whose codomain is the contractible groupoid on four vertices 0, 1, 2, 3 and whose domain is the union of the three copies of \(\mathbb{I}[2]\) spanned by the subsets of three of these four vertices that include the vertex 1, is a complicial anodyne extension.

D.5. Isofibrations between quasi-categories

Our first aim in this section is to integrate the class of isofibrations between quasi-categories into the results proven in §D.3. We start by proving Propositions 1.1.19 and 1.1.28, restated here for convenience.

D.5.1. Proposition.

(i) There is a solution to any lifting problem between the pushout product of a monomorphism \(i : X \hookrightarrow Y\) and the map \(\mathbb{I} \hookrightarrow \mathbb{I}\) and any isofibration \(f : A \twoheadrightarrow B\).

(ii) If \(i : X \hookrightarrow Y\) is a monomorphism and \(f : A \twoheadrightarrow B\) is an isofibration, then the induced Leibniz exponential map

\[
A^Y \xrightarrow{\text{id}_f} B^Y \times_{B^X} A^X
\]

is again an isofibration.
(iii) If \( i: X \hookrightarrow Y \) is a monomorphism and \( f: A \twoheadrightarrow B \) is a trivial fibration, then the induced Leibniz exponential map

\[
A^Y \xrightarrow{\hat{\imath}_! f} B^Y \times_{B^X} A^X
\]

is again a trivial fibration.

(iv) If \( i: X \hookrightarrow Y \) is in the class generated by the inner horn inclusions and the map \( \mathbb{I} \hookrightarrow \mathbb{I} \) and \( f: A \twoheadrightarrow B \) is an isofibration, then the induced Leibniz exponential map

\[
A^Y \xrightarrow{\hat{\imath}_! f} B^Y \times_{B^X} A^X
\]

is a trivial fibration.

**Proof.** It suffices to construct the lift of (i) in marked simplicial sets and then forget the markings. By Lemma D.1.13, \( \mathbb{I} \hookrightarrow \mathbb{I} \) is a complicial anodyne extension, when \( \mathbb{I} \) is assigned its natural maximal marking. Thus by Proposition D.3.9, the Leibniz product of the minimally marked monomorphism \( i \) with this map is again a complicial anodyne extension. By Theorem D.4.19, an isofibration defines a complicial isofibration between naturally marked quasi-categories, so the postulated lift exists.

Parts (ii) and (iv) follow from the conclusion of (i) and a similar result, Corollary D.3.12 that shows that the pushout product of a monomorphism and an inner horn inclusion can be factored as a sequence of pushouts of inner horn inclusions. By transposing across the two-variable adjunction between the pushout product and the Leibniz exponential, these results imply that the map \( i \hat{\Phi}_! f \) lifts against the inner horn inclusions and against the map \( \mathbb{I} \hookrightarrow \mathbb{I} \). Part (iii) follows by a similar argument from an easier observation: that the pushout product of two monomorphisms is again a monomorphism. \( \square \)

**D.5.2. Proposition.** For a map \( f: A \to B \) of quasi-categories the following are equivalent:

(i) \( f \) is a trivial fibration

(ii) \( f \) is both an isofibration and an equivalence

(iii) \( f \) is a split fiber homotopy equivalence: an isofibration admitting a section \( s \) that is also an equivalence inverse via a homotopy from \( \text{id}_A \) to \( sf \) that composes with \( f \) to the constant homotopy from \( f \) to \( f \).

**Proof.** For (i)\( \Rightarrow \) (ii), observe that the simplex boundary inclusions generate the monomorphisms of simplicial sets under coproduct, pushout, and sequential composition (see Lemma C.5.9), so the lifting property of (1.1.25) implies that the trivial fibrations lift against all monomorphisms of simplicial sets, and in particular against the monomorphisms that detect the class of isofibrations. Thus, trivial fibrations are isofibrations. By the same lifting property, every trivial fibration admits a section

\[
A \xrightarrow{s} A \xleftarrow{i} B
\]

To show that \( s \) defines an inverse homotopy equivalence to \( f \), observe that the other rectangle built from the constant homotopy \( \pi: A \times \mathbb{I} \to A \)

\[
A + A \xrightarrow{(\text{id}_A, sf)} A \xrightarrow{i} f \xrightarrow{f} B
\]

562
commutes since $f sf = f$. The lift defines a homotopy between $\text{id}_A$ and $sf$ completing the proof that trivial fibrations are equivalences. And note in fact that the equivalence just constructed is a split fiber homotopy equivalence, proving that (i)$\Rightarrow$(iii).

To prove (ii)$\Rightarrow$(iii), suppose that $f$ is an isofibration with equivalence inverse $g$. By Lemma D.5.3 below, the homotopies $\alpha$ from $\text{id}_A$ to $gf$ and $\beta$ from $fg$ to $\text{id}_B$ may be chosen so as to define a “half-adjoint equivalence,” meaning that there exists a map $\Phi : A \times \mathbb{I}[2] \to B$, where $\mathbb{I}[2]$ is the contractible groupoid on three objects, whose boundary is formed by $f \alpha$, $\beta f$, and the constant homotopy $\text{id}_f := f \pi$.

Applying Proposition D.5.1(i) to the monomorphism $\emptyset \hookrightarrow B$, we find that we can lift the homotopy $\beta$ between $fg$ and $\text{id}_B$ along $f$

\[
\begin{array}{c}
\xymatrix{ B \ar[r]^s & A \\
 B \ar[u]^{i_0} \ar[r]_s & B \times \mathbb{I} \ar[u]_f \ar[r]_{\beta} & B \\
}
\end{array}
\]

The composite map $s$ defines a strict section of $f$, while the lift defines a homotopy $\gamma$ from $g$ to $s$.

Applying Proposition D.3.9, Theorem D.4.19, and Example D.4.23, we can solve the lifting problem

\[
\begin{array}{c}
\xymatrix{ A \times \Lambda^1[\mathbb{I}[2]] \ar[r]^{(\alpha, \gamma f)} \ar@{-->}[d]^\eta & A \\
 A \times \mathbb{I} \ar[r]_{\delta^1} & \Lambda^2[\mathbb{I}[2]] \ar[d]^\Phi \\
 & B \\
 A \ar[u]^\eta \ar[r]_{\delta^1} & A \times \mathbb{I} \ar[r]_{\Phi} & B \ar[u]_f \\
 & A \\
}
\end{array}
\]

The lift defines a composite homotopy $\eta$ from $\text{id}_A$ to $sf$ so that $f \eta = f \pi$ is the constant homotopy. This data exhibits $f$ as a split fiber homotopy equivalence.

Finally, for (iii)$\Rightarrow$(i) to prove that $f : A \to B$ is a trivial fibration it suffices to show that the Leibniz exponential constructed in the diagram below is surjective on vertices (a vertex in its codomain defining a lifting problem that any lift would solve):

\[
\begin{array}{c}
\xymatrix{ A^\Delta[n] \ar[r] \ar@{-->}[d] & A^{\delta \Delta[n]} \ar[d] \\
 B^\Delta[n] \ar[r] & B^{\delta \Delta[n]} \\
}
\end{array}
\]

By Proposition 1.1.19, the maps displayed with two heads are all isofibrations. Moreover, equivalences are preserved by exponentiation, so the outer vertical maps are also equivalences.

The point of promoting the equivalence $f$ to a split fiber homotopy equivalence is that surjective equivalences are also stable under pullback, which defines a simplicial functor between slice categories and surjective equivalences live fully in these slice categories. Since the equivalences satisfy the 2-of-3 property (Exercise 1.1.viii) it now follows that the Leibniz exponential is both an isofibration and

---

*See Theorem 1.4.7 and Proposition 2.1.12 for an explanation of this terminology.*
equivalence. By (ii)⇒(iii), this map admits a section and in particular is surjective on vertices. Thus, we conclude that split fiber homotopy equivalences are trivial fibrations. □

D.5.3. LEMMA. Any equivalence of quasi-categories

\[
\begin{align*}
A & \xrightarrow{i_0} A \\
A \times \mathbb{I} & \xrightarrow{\alpha} A \\
A & \xrightarrow{i_1} B \\
B & \xrightarrow{g} A \\
B \times \mathbb{I} & \xrightarrow{\beta} B \\
B & \xrightarrow{i_1} B
\end{align*}
\]

can be extended to a half-adjoint equivalence of quasi-categories, with an additional coherence homotopy \(\Phi: A \times \mathbb{I}[2] \to B\) whose boundary is comprised of the three homotopy coherent isomorphisms:

\[
\begin{array}{ccc}
f \alpha & \Phi & \beta f \\
f & & f \id_f
\end{array}
\]

at the cost of replacing one of the homotopies \(\alpha\) or \(\beta\).

The proof is by a simplicial reinterpretation of the 2-categorical argument that proves Proposition 2.1.12.

PROOF. Consider an equivalence of quasi-categories as in the statement. By Example D.4.23, the homotopies \(f \alpha\) and \(\beta f\) admit some composite defined by solving the lifting problem

\[
\begin{array}{ccc}
A \times \mathbb{I} & \xrightarrow{\delta^1} A \times \mathbb{I}[2] \\
\psi & & \psi
\end{array}
\]

Restriction along the non-identity involution \(\mathbb{I} \to \mathbb{I}\) defines the inverse of any homotopy, denoted by \((-)^{-1}\). We will replace \(\alpha\) by the composite \(\alpha' := g \psi^{-1} \cdot \alpha\) defined by solving the lifting problem

\[
\begin{array}{ccc}
A \times \mathbb{I}[2] & \xrightarrow{\delta^1} A \times \mathbb{I}[2] \\
\alpha' & & \varrho
\end{array}
\]

and show that this homotopy defines a half-adjoint equivalence with \(\beta\).

The witness to the half-adjoint equivalence will be obtained by solving a final lifting problem

\[
\begin{array}{ccc}
A \times \mathbb{I}[3] & \xrightarrow{\delta^1} A \times \mathbb{I}[2] \\
\varphi & & \varphi
\end{array}
\]

564
involving an extension along \( \Lambda^1[\mathbb{I}[3]] \hookrightarrow \mathbb{I}[3] \), whose codomain is the contractible groupoid with four objects 0, 1, 2, 3 and whose domain is the union of the three faces \( \mathbb{I}[2] \) which contain the vertex 1. This is permitted by Exercise D.4.ii.

It remains to define the faces of the “horn of homotopy coherent isomorphisms” \( \Gamma \) which is built from the homotopy coherent isomorphisms

![Diagram](image)

The 3rd face is \( f \Xi : A \times \mathbb{I}[2] \rightarrow B \) while the second face is the composite

\[
A \times \mathbb{I}[2] \xrightarrow{A \times q} A \times \mathbb{I} \xrightarrow{f} B
\]

where \( q : \mathbb{I}[2] \rightarrow \mathbb{I} \) is the unique map defined by 0, 2 ↦ 0 and 1 ↦ 1. It remains to define the 0th face. For this, we first extend along another horn \( \Lambda^1[\mathbb{I}[3]] \hookrightarrow \mathbb{I}[3] \) of homotopy coherent isomorphisms in \( B^A \) as depicted below

![Diagram](image)

Here the 0th face is \( \Psi^{-1} \), the 3rd face is the composite

\[
A \times \mathbb{I}[2] \xrightarrow{A \times q} A \times \mathbb{I} \xrightarrow{\beta f} B
\]

and the 2nd face is the composite

\[
A \times \mathbb{I}[2] \xrightarrow{A \times d} A \times \mathbb{I}[2] \times \mathbb{I} \xrightarrow{\Psi \times \mathbb{I}} B \times \mathbb{I} \xrightarrow{\beta} B
\]

where \( d : \mathbb{I}[2] \rightarrow \mathbb{I}[2] \times \mathbb{I} \) is the unique map defined by 0 ↦ (2, 0), 1 ↦ (2, 1), and 2 ↦ (0, 1). The \( \delta^1 \)-face of this horn can be used to define a final horn \( \Lambda^1[\mathbb{I}[3]] \hookrightarrow \mathbb{I}[3] \) of homotopy coherent isomorphisms in \( B^A \) as depicted below

![Diagram](image)

whose 3rd face is degenerate, whose 3rd face is an inversion that swaps the first two vertices of the \( \delta^1 \)-face \( A \times \mathbb{I}[2] \rightarrow B \) just defined, and whose 0th face is the composite

\[
A \times \mathbb{I}[2] \xrightarrow{A \times c} A \times \mathbb{I}[2] \times \mathbb{I} \xrightarrow{\Psi \times \mathbb{I}} B \times \mathbb{I} \xrightarrow{\beta} B
\]
where \( c: \mathbb{I}[2] \to \mathbb{I}[2] \times \mathbb{I} \) is the unique map defined by \( 0 \mapsto (2, 0), 1 \mapsto (0, 0), \) and \( 2 \mapsto (0, 1) \). The filler defines the desired 0th face

\[
\begin{array}{c}
\text{fg} \\
f \\
\text{fg} \\
\end{array}
\]

that completes the horn \( \Gamma: A \times \Lambda^1[\mathbb{I}[3]] \to B \) whose filler defines the witness for the half-adjoint equivalence between \( \alpha' \) and \( \beta \).

D.5.4. Proposition. A Kan fibration is a trivial fibration if and only if its fibers are contractible.

Proof. By pullback stability of the class of trivial fibrations, it is clear that the fibers of a trivial fibration are contractible Kan complexes. For the converse, our task is to show that any lifting problem

\[
\partial \Delta[n] \xrightarrow{e} E \\
\downarrow \\
\Delta[n] \xrightarrow{b} B
\]

has a solution. The inclusion of the \( n \)-sphere into \( n \)-simplex factors as

\[
\partial \Delta[n] \xrightarrow{\partial \Delta[n] \times i_1} \partial \Delta[n] \times \Delta[1] \hookleftarrow \Delta[n] \times \Delta[1] \xrightarrow{q} \Delta[n]
\]

where \( q \) is the quotient map defined on vertices by \( (j, i) \mapsto j \cdot i \). The inclusion \( \partial \Delta[n] \times i_1 \) is an anodyne extension; hence, there is a lift

\[
\partial \Delta[n] \xrightarrow{e} E \\
\downarrow \\
\partial \Delta[n] \times \Delta[1] \xrightarrow{q} \Delta[n] \xrightarrow{b} B
\]

This lift in turn produces a new lifting problem, which we restrict to the sphere sitting over the other endpoint of the cylinder as in the following diagram:

\[
\begin{array}{c}
\partial \Delta[n] \\
\downarrow \\
\Delta[n] \xrightarrow{\partial \Delta[n] \times i_1} \Delta[n] \times \Delta[1] \xrightarrow{q} \Delta[n] \xrightarrow{b} B
\end{array}
\]

By construction, the sphere in this restricted lifting problem lives in the fiber over the vertex \( \{0\} \) of the \( n \)-simplex \( b \) in \( B \); hence, there exists a solution to this lifting as displayed since that fibre is contractible by assumption. Taking the pushout of left-hand square of (D.5.5) we obtain the lifting problem that is the right-hand square in the following diagram:

\[
\begin{array}{c}
\partial \Delta[n] \\
\downarrow \\
\Delta[n] \xrightarrow{\Delta[n] \times i_1} \Delta[n] \times \Delta[1] \xrightarrow{q} \Delta[n] \xrightarrow{b} B
\end{array}
\]
Here the horizontal map \( m \) is induced by maps \( \ell \) and \( k \) in (D.5.5). The middle vertical is the Leibniz product of a monomorphism and anodyne extension; hence this map is an anodyne extension, and the displayed lift exists. Finally, restriction to the endpoint over the vertex \([1]\) of the cylinder, that is composing with the square on the left in the diagram above, defines a solution to the original lifting problem.

\[ \square \]

D.6. Equivalence between slices and cones

The work of §D.4 also enables us to supply full proofs of the results sketched in §4.2, which follow easily from the combinatorial work done in §D.2. Recall in particular Proposition D.2.17, which shows that the map of augmented simplicial sets

\[ s^{n,m} : \Delta[n] \cdot \Delta[m] \to \Delta[n] \star \Delta[m] \in sSet_{+}^{\Delta_+ \times \Delta_+} \]

is a marked homotopy retract equivalence. We argue now that such maps induce equivalences upon mapping into quasi-categories.

D.6.1. Lemma. Let \( A \) be a quasi-category and let \( I \to J \) be a map of simplicial sets that extends to a marked homotopy equivalence. Then the induced map \( A^I \to A^J \) is an equivalence of quasi-categories.

Proof. Equip \( A \) with its natural marking so that by Theorem D.4.13 it defines a complicial set. The marked homotopy equivalence defines maps

\[ A^I \to A^I, \quad A^I \to A^I, \quad A^I \to (A^I)^{\Delta[1]} \Rightarrow, \quad A^I \to (A^I)^{\Delta[1]} \Rightarrow. \]

By Lemma D.4.16, the complicial sets \( A^I \) and \( A^J \) are also naturally marked quasi-categories. By Exercise 1.1.v, the inclusion \( \Delta[1] \Rightarrow \Rightarrow \to \Rightarrow \) is a complicial anodyne extension so by Proposition D.3.9, the restriction maps \( (A^I)^{\Delta[1]} \Rightarrow (A^J)^{\Delta[1]} \Rightarrow \) are trivial fibrations of marked simplicial sets. In particular, there exists lifts

\[ (A^I)^{\Delta[1]} \Rightarrow (A^J)^{\Delta[1]} \Rightarrow \]

Forgetting markings, this data defines an inverse equivalence of categories to \( A^I \to A^J \). \[ \square \]

In order to use this result to verify that the canonical map of augmented simplicial sets \( s^{X,Y} : X \cdot Y \to X \star Y \) is also a weak equivalence in a suitable sense, we first prove that these diagrams are Reedy monomorphic.

D.6.2. Lemma. The latching maps for the diagrams \( F, F_\ast \in sSet_{+}^{\Delta_+ \times \Delta_+} \) defined by

\[ F^{n,m} := \Delta[n] \cdot \Delta[m] \quad \text{and} \quad F_\ast^{n,m} := \Delta[n] \star \Delta[m] \]

are the maps

\[ (\partial \Delta[n] \hookrightarrow \Delta[n]) \Rightarrow (\partial \Delta[m] \hookrightarrow \Delta[m]) \quad \text{and} \quad (\partial \Delta[n] \hookrightarrow \Delta[n]) \Rightarrow (\partial \Delta[m] \hookrightarrow \Delta[m]), \] (D.6.3)

which are both monomorphisms. Hence, both \( F \), \( F_\ast \) are Reedy monomorphic.
Proof. By direct calculation,

\[(\partial \Delta[n] \hookrightarrow \Delta[n]) \ast (\partial \Delta[m] \hookrightarrow \Delta[m]) \cong \partial \Delta[n+1+m] \hookrightarrow \Delta[n+1+m],\]

which is clearly a monomorphism. It follows by Proposition C.2.9(vi) and Lemma C.5.9 that Leibniz joins of monomorphisms are monomorphisms.

For the analogous result for the fat join, observe first that \((\partial \Delta[-1] \hookrightarrow \Delta[-1]) \hat{\diamond} (X \hookrightarrow Y) \cong (X \hookrightarrow Y)_n \sqcup \bigcup_{([n], [m])} X_n \times Y_m \sqcup Y_n\). Thus, we see that for any monomorphisms of simplicial sets \(X \hookrightarrow Y\) and \(U \hookrightarrow V\), the square

\[
\begin{array}{ccc}
(U \circ X)_n & \rightarrow & (V \circ X)_n \\
\downarrow & & \downarrow \\
(U \circ Y)_n & \rightarrow & (V \circ Y)_n
\end{array}
\]

is a pullback in the category of sets. For any pullback square comprised of monomorphisms in the category of sets, the pushout inside the square is constructed by the joint image of the lower and right-hand legs: in particular the map \((U \circ X)_n \sqcup (U \circ X)_n \hookrightarrow (V \circ Y)_n\) is a monomorphism. Thus, the Leibniz fat join of two monomorphisms

\[\hat{\circ} \, (X \hookrightarrow Y)\]

is a monomorphism as claimed. By Proposition C.2.9(vi) this argument extends also to non-terminally augmented simplicial sets, since these can be built as cell complexes from the cell boundary inclusions \(\partial \Delta[n] \hookrightarrow \Delta[n]\) for \(n \geq -1\).

Now by Definition C.4.16, the latching map at the object \(([n], [m]) \in \Delta_+ \times \Delta_+\) is the map on weighted colimits induced by the maps (D.6.3) of weights. Applying Corollary C.5.16 to the weak factorization system on \(s\mathcal{S}et_+\) whose left class is the monomorphisms, it follows that the latching maps for \(F\) and \(F_\star\) are monomorphisms as claimed, proving that these diagrams are Reedy monomorphic. \(\square\)

D.6.4. Proposition. For all simplicial sets \(X\) and \(Y\), the natural map \(s : X \circ Y \rightarrow X \star Y\) induces an equivalence of quasi-categories \(A_X \circ Y \simeq A_X \star Y\) for all quasi-categories \(A\).

Lurie gives an alternate proof of this result in [74, 4.2.1.2].

Proof. For any pair of terminally augmented simplicial sets \(X\) and \(Y\) we define their external product \(X \square Y \in \mathcal{S}et^{\Delta^+ \times \Delta^+}_{\Delta^+ \times \Delta^+}\) to be the functor that takes an object \(([n], [m])\) to the set \(X_n \times Y_m\). We can view this functor as a weight for the diagrams \(F_\circ\) and \(F_\star\) introduced in Lemma D.6.2 and use Definition A.6.2 and cocontinuity of the join and fat join bifunctors (in the full subcategory \(s\mathcal{S}et \hookrightarrow s\mathcal{S}et_+\) of terminally augmented simplicial sets) to compute the weighted colimits:

\[
\text{colim}_{X \square Y} F_\circ \cong \int_{([n], [m]) \in \Delta_+ \times \Delta_+} \prod_{X_n \times Y_m} \Delta[n] \circ \Delta[m] \cong \left( \int_{[n] \in \Delta_+} \prod_{X_n} \Delta[n] \right) \circ \left( \int_{[m] \in \Delta_+} \prod_{Y_m} \Delta[m] \right) \cong X \circ Y
\]

568
Similarly, \( \text{colim}^{\Delta \times \Delta^\text{op}}_{X \Box Y} F_* \cong X \star Y \).

A direct verification shows that the latching maps of the augmented bisimplicial set \( X \Box Y \in \text{Set}^{\Delta^\text{op} \times \Delta^\text{op}} \) are monomorphisms.\footnote{This follows because \( \Delta \times \Delta^* \) is an \textit{elegant Reedy category}: every element of a presheaf indexed by this category is a degeneracy of some non-degenerate element in a unique way [15].} Hence by Corollary C.5.16, the weighted colimit functor

\[
\text{colim}^{\Delta \times \Delta^\text{op}}_{X \Box Y} : \; \text{sSet}^{\Delta \times \Delta^*} \to \text{sSet}
\]

is a left Leibniz bifunctor with respect to any weak factorization systems of our choosing on \( \text{sSet} \).

By Lemma D.6.1, the components \( s^{n,m} : \Delta[n] \otimes \Delta[m] \to \Delta[n] \star \Delta[m] \) are weak equivalences in the Joyal model structure, as these are characterized as those maps that induce equivalences upon mapping into an arbitrary quasi-category. So Proposition D.2.17 and Lemma D.6.2 establish that the natural transformation \( s : F_* \to F_* \) is a pointwise weak equivalence between Reedy monomorphic objects in \( \text{sSet}^{\Delta \times \Delta^*} \). By the dual of Ken Brown’s Lemma C.1.10, the induced map on weighted colimits \( s^{X,Y} : X \star Y \to X \star Y \) is then a weak equivalence in the Joyal model structure, which means exactly that it induces an equivalence of quasi-categories \( A^{X \star Y} \simeq A^{X \star Y} \) for all quasi-categories \( A \) as claimed. \( \square \)

In particular, for any quasi-category \( A \), there are natural equivalences \( A^{A^* \star J} \simeq A^{A^* \star J} \) and \( A^{\star A^*} \simeq A^{\star A^*} \) over \( A \times A^* \). By Lemma 4.2.3 the codomains pullback to define the quasi-categories of cones under or over a diagram \( d : J \to A \), respectively. However, as discussed in Warning 4.2.10, the domains do not pull back to the slice quasi-categories \( A_{/d} \) and \( d/A \) of Definition D.2.8. Nonetheless, we can use the equivalence between the join and fat join constructions to prove that \( A_{/d} \approx \text{Hom}_{A^*}(\Delta, d) \) and \( d/A \approx \text{Hom}_{A}(d, \Delta) \) over \( A \) and do so now.

**D.6.5. Proposition.** For any diagram \( d : J \to A \) indexed by a simplicial set \( J \) and valued in a quasi-category \( A \), there are natural equivalences

\[
\begin{align*}
A_{/d} &\xrightarrow{\sim} \text{Hom}_{A^*}(\Delta, d) \\
A &\xrightarrow{\text{res}} A
\end{align*}
\]

\[
\begin{align*}
d/A &\xrightarrow{\sim} \text{Hom}_{A}(d, \Delta) \\
A &\xrightarrow{\text{res}} A
\end{align*}
\]

between the slice quasi-categories and the quasi-categories of cones.

**Proof.** We appeal to Lemma C.5.22.

To begin, recall the adjunction of Definition D.2.8

\[
\begin{tikzcd}
\text{sSet} \ar[rr, shift right=1] \ar[rr, bend left=10, shift right=1] & & \text{}/\text{sSet} \\
\text{sSet} \ar[rr, shift left=1] \ar[rr, bend right=10, shift left=1] & & \text{}/\text{sSet}
\end{tikzcd}
\]

which gives a correspondence, for a simplicial set \( I \) and a map \( d : J \to A \), between maps \( I \star J \to A \) under \( J \) and maps of simplicial sets \( I \to A_{/d} \). A right adjoint to the fat join functor \( - \star J : \text{sSet} \to \text{}/\text{sSet} \) can be calculated similarly. By the defining pushout of Definition 4.2.2, the data of a map \( I \star J \to A \)

\[
\begin{tikzcd}
A_{/d} \ar[r, shift left=1, bend left=10, shift right=1] & \text{Hom}_{A^*}(\Delta, d) \\
A \ar[r, shift left=1, bend right=10, shift right=1] & \text{Hom}_{A}(d, \Delta)
\end{tikzcd}
\]

\[
\begin{tikzcd}
A_{/d} \ar[r, shift left=1, bend left=10, shift right=1] & \text{Hom}_{A^*}(\Delta, d) \\
A \ar[r, shift left=1, bend right=10, shift right=1] & \text{Hom}_{A}(d, \Delta)
\end{tikzcd}
\]
under $J$ displayed below-left transposes to the data displayed below-right

$$
(I \times J) \sqcup (I \times J) \xrightarrow{\pi_{I \sqcup J}} I \sqcup J \xrightarrow{- \sqcup d} \sqcup_{\Delta, d} I \sqcup J \xrightarrow{\pi_{I \sqcup J}} A
$$

whence we see that that the value of the right adjoint to $- \circ J$

$$
s_{\mathcal{S}et} \xrightarrow{\bot} \sqcup_{\Delta, d} \mathcal{S}et
$$

at $d: J \to A$ defines the $\infty$-category of cones $\text{Hom}_A(\Delta, d)$ over $d$.

The natural map $s^{X,Y}: X \diamond Y \to X \star Y$ of Lemma D.2.14 defines a natural transformation

$$
\Delta[n] \xrightarrow{s} \sqcup_{\Delta, d} \mathcal{S}et
$$

that Proposition D.6.4 is a pointwise weak equivalence in the (sliced) Joyal model structure. Note that by adjunction, $\text{Hom}_A(\Delta, d)$ is isomorphic to the simplicial set defined by mapping from the cosimplicial object $\Delta[n] \circ J$ to $d: J \to A$ in $\sqcup \mathcal{S}et$, and $A_{/d}$ is isomorphic to the simplicial set defined by mapping from the cosimplicial object $\Delta[n] \star J$ to $d: J \to A$ in $\sqcup \mathcal{S}et$. In particular, the mate of the natural transformation $s$ defines a natural comparison map $\hat{s}: A_{/d} \to \text{Hom}_A(\Delta, d)$; since $s^{[n],\emptyset}$ is the identity, this natural comparison map lies over $A$.

To apply Lemma C.5.22, we need only verify that both cosimplicial objects are Reedy cofibrant, which can be verified by a direct calculation along the lines of that given in the proof of Lemma D.6.2. Lemma C.5.22 now proves that the map $\hat{s}: A_{/d} \to \text{Hom}_A(\Delta, d)$ define a “weak equivalence” of simplicial sets over $A$. As discussed in Remark C.5.23, these “weak equivalences” can be taken to be any class of maps containing the trivial fibrations and closed under the 2-of-3 property. Here we take the weak equivalences to be the weak equivalences of the Joyal model structure, and since $A_{/d}$ and $\text{Hom}_A(\Delta, d)$ are quasi-categories, this proves that this map defines an equivalence of quasi-categories over $A$, as desired. □

In the case $J = 1$, a diagram $a: 1 \to A$ defines an element of the quasi-category $A$, and we have the same result with different notion.

**D.6.6. Corollary.** Let $a: 1 \to A$ define an element of a quasi-category $A$. Then there are canonical equivalences $A_{/a} \simeq \text{Hom}_A(A, a)$ and $a/A \simeq \text{Hom}_A(a, A)$ over $A$.

**Proof.** When $J = 1$, the constant diagram functor $\Delta: 1 \to A^I$ appearing in Proposition D.6.5 reduces to the identity functor on $A$. □
D.7. Equivalences and saturation

Having proven the required results about quasi-categories and isofibrations we indulge in a final
section that develops a bit more of the general theory of complicial sets.

In Lemma D.4.2, we observed that the marked edges in a complicial set should be interpreted as
equivalences, in a suitable sense. Below we demonstrate that a similar interpretation is appropriate
for the higher-dimensional marked simplices as well. Consequently, if a complicial set has a property
such as included in Definition D.4.4 of the natural marking that all simplices in dimension \( r > n \) are
marked—i.e., is \( n \)-trivial in terminology we will presently introduce—we may interpret that condition
as demanding that all simplices in dimension \( r > n \) are weakly invertible. Having understood that
every marked simplex in a complicial set is an equivalence, we are lead to consider complicial sets that
satisfy the converse of this condition, in which every equivalence is marked. Such saturated complicial
sets are especially important, and we introduce the terminology \( n \)-complicial set to describe an \( n \)-trivial
saturated complicial set. The Kan complexes are precisely the 0-complicial sets while the quasi-categories
are precisely the 1-complicial sets. As this pattern suggests, the \( n \)-complicial sets define a well-behaved
model for \((\infty, n)\)-categories in the sense that the full subcategory of such defines a cartesian closed
\( \infty \)-cosmos, as we prove Proposition E.3.9.

To start our exploration of the higher-dimensional invertible simplices in a complicial set, we
introduce an equivalence relation on simplices in a complicial set. To define it, we extend the notation
of Definition D.1.6: for \( n \geq 1 \) and \( 0 \leq j < k \leq n \) write \( \Delta^{j,k}[n] \) for the pushout of
\( \Delta^j[n] \hookrightarrow \Delta^k[n] \).

D.7.1. Definition. For every marked simplicial set \( A \), we define an equivalence relation \( \sim_A \) on the set
of \( n \)-simplices that is generated by the following relation: two \( n \)-simplices \( \alpha, \beta \) in a marked simplicial
set \( A \) are complicial companions if there exists an \( (n+1) \)-simplex \( \tau \) in \( A \) and \( 0 \leq k \leq n \) so that

- \( \tau \) is both \( k \)-admissible and \((k+1)\)-admissible.
- \( \alpha = \tau \cdot \delta^k \) and \( \beta = \tau \cdot \delta^{k+1} \).

\[
\begin{array}{ccc}
\Delta[n] & \xrightarrow{\delta^k} & \Delta^{k,k+1}[n+1] & \xleftarrow{\delta^{k+1}} & \Delta[n] \\
\downarrow{\alpha} & & \downarrow{\tau} & & \downarrow{\beta} \\
A & & & & \\
\end{array}
\]

For example, vertices of a marked simplicial set are complicial companions just when they are
connected by a finite zig-zag of marked edges.

D.7.2. Lemma. If \( A \) is a complicial set and if \( \alpha \approx_A \beta \) are \( n \)-simplices of \( A \) that are complicial companions, then \( \alpha \) is marked if and only if \( \beta \) is marked.

Proof. By induction it suffices to consider the generating relation. Suppose \( \alpha \) and \( \beta \) appear,
respectively, as the \( k \)th and \((k+1)\)th faces of a \( k \)-admissible and \((k+1)\)-admissible \((n+1)\)-simplex \( \tau \);
in particular, these conditions imply apriori that all of the codimension-one faces of \( \tau \) except perhaps
\( \alpha \) and \( \beta \) are marked. If \( \beta \) is marked, then the markings of the \( k \)-admissible \((n+1)\)-simplex \( \tau \) extend as
indicated in the solid arrow diagram

\[
\Delta^k[n+1] \xrightarrow{\tau} \Delta^k[n+1]' \xrightarrow{\xi} A
\]

and hence the dashed extension exists by Definition D.1.9. Since all codimension faces of \(\Delta^k[n+1]''\) are marked, this tells us that \(\alpha\) is marked also. If \(\alpha\) is assumed to be marked instead, we apply the analogous argument, regarding \(\tau\) as an \((k+1)\)-admissible \((n+1)\)-simplex. □

D.7.3. Lemma. In a complicial set \(A\), every \(n\)-simplex \(\alpha\) is the complicial companion of a pair of \(n\)-simplices \(\hat{\alpha}\) and \(\check{\alpha}\) with the property that \(\hat{\alpha} \cdot \delta^0\) is maximally marked and \(\check{\alpha} \cdot \delta^n\) is maximally marked.

In fact, as the proof will show, the face \(\check{\alpha} \cdot \delta^n\) can be taken to be degenerate at the final vertex of \(\alpha\), while the face \(\hat{\alpha} \cdot \delta^0\) can be arranged to be degenerate at the initial vertex of \(\alpha\).

Proof. We explain the construction of the complicial companion \(n\)-simplex \(\check{\alpha}\) with \(\check{\alpha} \cdot \delta^n\) degenerate at the initial vertex of \(\alpha\); the construction of \(\hat{\alpha}\) is the odd dual of Remark D.1.8. To prove that \(\alpha \simeq A_n \hat{\alpha}\), we build a diagram starting from the left:

\[
\begin{align*}
\Delta[n] & \xrightarrow{\delta^1} \Delta^1[n+1] \xrightarrow{\tau_1} \Delta^2[n+1] \xrightarrow{\alpha^2} \ldots \Delta^n[n+1] \xrightarrow{\tau_n} A \\
\alpha = a^1 & \xrightarrow{\delta^2} \Delta^2[n+1] \xrightarrow{\alpha^3} \ldots \Delta^n[n+1] \xrightarrow{\delta^{n-1}} \Delta^{n+1}[n+1] \xrightarrow{\alpha^n = \check{\alpha}} A
\end{align*}
\]

To explain the idea of the construction of the sequence of complicial companion simplices

\[\alpha = \alpha^1 \simeq A_n \alpha^2 \simeq A_n \alpha^3 \cdots \alpha^{n-1} \simeq A_n \alpha^n = \check{\alpha}\]

consider the sequence of \(n\) composable edges \(f_{n-1,n}, \ldots, f_{1,2}\) along the spine of \(\alpha = \alpha^1\). In \(\alpha^2\), the initial edge is degenerate, the 2nd edge is a composite \(f_{1,2} \cdot f_{0,1}\), and the final \(n-2\) composable edges along the spine coincide with the corresponding edges in the original sequence. In \(\alpha^3\), the first two edges are degenerate, the 3rd edge is a composite \(f_{2,3} \cdot f_{1,2} \cdot f_{0,1}\), and the final \(n-3\) edges coincide with the original sequence. In \(\alpha^n = \hat{\alpha}\), the initial \(n-1\)-edges are degenerate and the last edge is a composite of the original sequence of \(n\) edges.

Inductively starting from the left, we will build the simplex \(\tau^i\) by filling an admissible horn \(\Lambda^i[n+1]\) whose \(i-1\)th face is the simplex \(\alpha^{i-1}\) defined in the previous stage and whose \(i\)th face is the simplex \(\alpha^i\) used in the next stage. The admissible horn is itself built by extending a “generalized admissible horn” that is defined by gluing \(\alpha^{i-1}\) to a degenerate simplex of dimension \(i\). To extend from the generalized admissible horn to the admissible horn \(\Lambda^i[n+1]\), a series of admissible simplices are attached to admissible inner horns \(\Lambda^k[m]\) starting in dimension \(m = 2\). For each of these admissible inner horns,
the vertex \( k \) is mapped to the vertex \( i \) of the simplex \( \tau^i \) being built, which is to say that all of the composites are being formed at a single vertex.

Writing \( \alpha^1 \) for the original \( n \)-simplex \( \alpha \), the simplex \( \tau^2 \) is built by extending a generalized admissible horn defined by the pushout

\[
\begin{array}{c}
\Delta[1] \\
\Delta[n] \\
\Delta[2] \\
\Delta[1] \\
H^2 \\
\Delta[1] \\
A \\
\end{array}
\]

To extend this generalized admissible horn to a horn \( \Lambda^2[n+1] \) whose filler defines \( \tau^2 \) and \( \alpha^2 \), we first attach fillers for each injection \( \Lambda^1[2] \to H^2 \) that is not already filled in \( H^2 \) that sends the inner vertex to the vertex 2 of \( H^2 \), which is the final vertex of the \( \Delta[1] \) along which the \( \Delta[n] \) and \( \Delta[2] \) are being glued. We then attach fillers for each injection of a not-already-filled inner \( k \)-admissible 3-horn that sends the vertex \( k \) to the vertex 2 of \( H^2 \). Continuing inductively, we attach fillers for each injection of a not already filled \( k \)-admissible \( m \) simplex that sends \( k \) to the vertex 2. After attaching simplices in dimension \( m = n - 1 \), we will have built a 2-admissible \( n + 1 \) horn extending the original generalized admissible horn \( H^2 \). Its filler defines \( \tau^2 \) and \( \alpha^2 \). Note by construction that the initial edge of \( \alpha^2 \) is degenerate.

Assume now we’ve defined the simplex \( \alpha^{i-1} \) as the \( i - 1 \)th face of \( \tau^{i-1} : \Delta^{i-2,i-1}[n+1] \to A \). The simplex \( \tau^i \) is built by extending a generalized complicial horn defined by the pushout

\[
\begin{array}{c}
\Delta[i-1] \\
\Delta[n] \\
\Delta[i] \\
\Delta[i-1] \\
H^i \\
\Delta[i-1] \\
A \\
\end{array}
\]

We extend \( H^i \) to an admissible horn \( \Lambda^i[n+1] \) by attaching fillers for each injection of a \( k \)-admissible \( m \)-horn that is not filled already which sends the vertex \( k \) to the vertex \( i \). The filler for this admissible horn defines \( \tau^i \) and \( \alpha^i \). Note that by construction the image of the face of \( H^i \) spanned by the vertices \( 0, \ldots, i-1 \) is degenerate on the face spanned by the vertices \( 0, \ldots, i-2 \) of \( \alpha^{i-1} \), which is degenerate at the first vertex of \( \alpha \). Hence, the face of \( \alpha^i \) spanned by the vertices \( 0, \ldots, i-1 \) is degenerate at the first vertex of \( \alpha \). This constructs the desired sequence of complicial companion simplices connecting \( \alpha \) to an \( n \)-simplex \( \tilde{\alpha} \) whose initial codimension-1 face is degenerate, and in particular maximally marked. □

D.7.4. Definition. A marked simplicial set \( X \) is \( n \)-trivial if all \( r \)-simplices are marked for \( r > n \).
The full subcategory of $n$-trivial marked simplicial sets is reflective and coreflective

$$sSet_{n-tr}^+ \xleftarrow{\text{trv}_n} sSet^+ \xrightarrow{\text{core}_n}$$

in the category of marked simplicial sets. That is $n$-trivialization defines an idempotent monad on $sSet^+$ with unit the entire inclusion

$$X \hookrightarrow e \text{ trv}_n X$$
of a marked simplicial set $X$ into the marked simplicial set $\text{trv}_n X$ with the same marked simplices in dimensions $1, \ldots, n$, and with all higher simplices “made thin.” A complicial set is $n$-trivial if this map is an isomorphism.

The $n$-core $\text{core}_n X$, defined by restricting to those simplices whose faces above dimension $n$ are all thin in $X$, defines an idempotent comonad with counit the regular inclusion

$$\text{core}_n X \hookrightarrow r X.$$Again, a complicial set is $n$-trivial just when this map is an equivalence. As is always the case for a monad-comonad pair arising in this way, these functors are adjoints: $\text{trv}_n \dashv \text{core}_n$.

The subcategories of $n$-trivial marked simplicial sets assemble to define a string of inclusions with adjoints

$$sSet \xhookleftarrow{(-)^\sharp} sSet_{0-trv}^+ \xrightarrow{\text{trv}_1} sSet_{1-trv}^+ \xhookleftarrow{\text{core}_1} \ldots \xrightarrow{\text{trv}_{n-1}} sSet_{(n-1)-trv}^+ \xhookleftarrow{\text{core}_{n-1}} \ldots \xhookrightarrow{\text{trv}_n} sSet_{n-trv}^+ \xrightarrow{\text{core}_n} sSet^+$$

that filter the inclusion of simplicial sets, considered as maximally marked marked simplicial sets, into the category of all marked simplicial sets.

D.7.5. Lemma. The $n$-core of a complicial set is a complicial set.

Proof. Exercise D.7.i.

By contrast, the $n$-trivialization functor does not necessarily preserve complicial sets; see Exercise D.7.ii.

D.7.6. Remark. By contrast, the left adjoint, which just marks simplices in the appropriate dimension without changing the underlying simplicial set, does not preserve complicial structure; this construction is too naive to define the “freely invert $n$-arrows” functor from $(\infty, n)$-categories to $(\infty, n-1)$-categories, whose construction for $n = 1$ is given by Proposition D.4.25. For instance, the minimally marked 1-simplex $\Delta[1]$ defines a 1-trivial complicial set, but $0\text{-trv}(\Delta[1]) = \Delta[1]^{\sharp}$ is not a 0-trivial complicial set because its underlying simplicial set is not a Kan complex; see Exercise D.1.ii.

Recall Lemma D.4.3, which described two markings for the nerve of a 1-category which make it into a 1-trivial complicial set: marking only the identity arrows or marking all isomorphisms. Clearly the first of these options defines the minimal 1-trivial marking that makes the nerve of a 1-category into a complicial set. By Lemma D.4.2, the latter option defines the maximal marking that makes the nerve of a 1-category into a complicial set. We now introduce terminology to describe “maximally marked” 1-trivial complicial sets.
D.7.7. Definition. A complicial set is **1-saturated** if every equivalence it contains among its edges is marked.¹⁰

If a quasi-category is given a 1-saturated 1-trivial marking, then it is necessarily the natural marking of Definition D.4.4. Conversely, Theorem D.4.13 proves that the underlying simplicial set of any 1-trivial saturated complicial set is a quasi-category and the markings recover the natural markings.

Our aim is now to extend these notions to higher dimensions. To define equivalences and saturation in any dimension, it is helpful to reformulate the notion of 1-equivalence as a lifting property. To state it, we make use of a 3-simplex $\Delta[3]_{eq}$ in which the edges $\{02\}$ and $\{13\}$ are marked as well as all simplices in dimension greater than 1.

D.7.8. Proposition. 

(i) A 1-simplex in a complicial set $A$ is an equivalence if and only if defines the $\{12\}$-edge of a 3-simplex $\Delta[3]_{eq} \to A$.

(ii) A complicial set is 1-saturated if and only if it admits extensions along the entire inclusion

$$
\begin{array}{c}
\Delta[3]_{eq} \\
\downarrow \\
\Delta[3]^e
\end{array} \to A
$$

Proof. If $f$ is an equivalence, then the witnessing 2-simplices of Definition D.4.1 define the 3rd and 0th faces of an admissible horn $\Lambda^{1,2}[3] \to A$ that fills to define a thin 3-simplex define a thin 3-simplex

$$
\begin{array}{c}
1 \\
\overset{f}{\searrow} \\
2 \\
\overset{g}{\Rightarrow} \\
0 \\
\downarrow h \\
3
\end{array}
$$

of the form stipulated in (i). Conversely, the middle edge of any such 3-simplex then admits left and right inverses in the weaker sense of composing to marked edges, as witnessed by the 3rd and 0th faces:

$$
\begin{array}{c}
1 \\
\overset{f}{\searrow} \\
2 \\
\overset{g}{\Rightarrow} \\
0 \\
\downarrow h \\
3
\end{array}
$$

¹⁰Since the characterization of equivalences among edges requires prior agreement about which 2-simplices are marked, we typically apply Definition D.7.7 to 1-trivial complicial sets, in which case we say a 1-saturated 1-trivial complicial set is simply “saturated.” This terminology will agree with Definition D.7.9.
By Lemma D.4.2, the marked edge $j$ admits a right equivalence inverse $i$, and from this data we may build a 1-admissible 3-horn in which all 2-simplex faces are marked.

$$
\begin{array}{c}
1 & \overset{e}{\rightarrow} & 2 \\
\downarrow & & \downarrow \\
0 & \overset{e \cdot i}{\rightarrow} & 3
\end{array}
\quad \approx 

\begin{array}{c}
1 & \overset{e}{\rightarrow} & 2 \\
\downarrow & & \downarrow \\
0 & \overset{\alpha \cdot y}{\rightarrow} & 3
\end{array}
$$

By a complicial anodyne extension followed by a complicial thinness extension, we produce a thin 2-simplex that witnesses that $f$ admits a right equivalence inverse in the stricter sense of Definition D.4.1. The dual argument constructs the desired left equivalence inverse.

Now for (ii) recall that a complicial set is 1-saturated if every 1-equivalence is marked. By (i), this implies that for any $\Delta[3]_{eq} \to A$, the image of the middle edge should be marked. But in this case the complicial thinness extensions $\Delta^2[2]' \leftrightarrow_\epsilon \Delta^2[2]''$ and $\Delta^0[2]' \leftrightarrow_\epsilon \Delta^0[2]''$ imply that the first and last edges must be marked as well. This proves that a complicial set is 1-saturated if and only if it enjoys the postulated lifting property.

There are similar extension problems that can be used to define equivalences and detect saturation in any dimension, which are defined by forming the join of the inclusion $\Delta[3]_{eq} \cup_\epsilon \Delta[3]^d$ with simplices on one side or the other. It is somewhat subtle to characterize the $k$-equivalences in a complicial set unless that complicial set is $n$-trivial for some $n$ because the notion of $k$-equivalence depends upon composites of $k$-simplices, which are witnessed by $k + 1$-dimensional equivalences. In a general complicial set, the class of equivalences is defined coinductively rather than inductively. Despite this, there is a surprisingly simple characterization of the saturated complicial sets, in which all equivalences (yet to be defined) are marked:

D.7.9. DEFINITION (saturated complicial set). A complicial set is saturated if it admits extensions along the set of entire inclusions

$$
[\Delta[m] \star \Delta[3]_{eq} \star \Delta[n] \leftrightarrow_\epsilon \Delta[m] \star \Delta[3]^d \star \Delta[n] \mid n, m \geq -1].
$$

In fact, it suffices to require only extensions

$$
\begin{array}{c}
\Delta[3]_{eq} \star \Delta[n] \longrightarrow A \\
\downarrow \\
\Delta[3]^d \star \Delta[n]
\end{array}
\quad \quad
\begin{array}{c}
\Delta[n] \star \Delta[3]_{eq} \longrightarrow A \\
\downarrow \\
\Delta[n] \star \Delta[3]^d
\end{array}
$$

along inclusions of one-sided joins of the inclusion $\Delta[3]_{eq} \cup_\epsilon \Delta[3]^d$ with an $n$-simplex for each $n \geq -1$, and as it turns out only the left-handed joins or right-handed joins are needed.

By Proposition D.7.8, the $n = -1$ case of Definition D.7.9 asserts that every 1-equivalence in $A$, defined relative to the marked 2-simplices and marked 3-simplices, is marked. By Proposition D.7.8
again, the general extension property

\[
\begin{array}{c}
\Delta[n] \xrightarrow{\sigma} \Delta[3]_\text{eq} \star \Delta[n] \rightarrow A \\
\downarrow \\
\Delta[3]_\text{eq} \star \Delta[n]
\end{array}
\quad \leftrightarrow \quad
\begin{array}{c}
\Delta[3]_\text{eq} \rightarrow A_{/\sigma} \\
\downarrow \\
\Delta[3]_\text{eq}
\end{array}
\]

asserts that every 1-equivalence in the slice complicial set \(A_{/\sigma}\) is marked.

At first blush, Definition D.7.9 does not seem to be general enough. In the case of a vertex \(\sigma: \Delta[0] \rightarrow A\), 1-equivalences in \(A_{/\sigma}\) define 2-simplices in \(A\) whose \(\{01\}\)-edge is a 1-equivalence. In particular, a generic 2-simplex

\[
\begin{array}{c}
0 \xrightarrow{h} 1 \xrightarrow{f} 2 \xrightarrow{g} 3
\end{array}
\]

with no 1-equivalence edges along its boundary, does not define a 1-equivalence in any slice complicial set. However, there are admissible 3-horns that can be filled to define the pasted composites of \(\alpha\) with \(1_f\) and \(1_g\), respectively:

\[
\begin{array}{c}
0 \xrightarrow{h} 1 \xrightarrow{g} 2 \xrightarrow{f} 3 = \begin{array}{c}
0 \xrightarrow{h} 1 \xrightarrow{g} 2 \xrightarrow{f} 3
\end{array}
\end{array}
\quad \approx \quad
\begin{array}{c}
0 \xrightarrow{h} 1 \xrightarrow{g} 2 \xrightarrow{f} 3
\end{array}
\]

By the complicial thinness extension property, if any of \(\alpha\), \(\hat{\alpha}\), or \(\check{\alpha}\) are marked, then all of them are. That is, \(\alpha\), \(\hat{\alpha}\), and \(\check{\alpha}\) are complicial companions in the sense of Definition D.7.1. Lemma D.7.3 generalizes this construction to simplices of arbitrary dimensions.

D.7.10. Definition. In an \(n\)-trivial complicial set, an \(n\)-simplex \(\sigma: \Delta[n] \rightarrow A\) is an \(n\)-equivalence if it admits an extension

\[
\begin{array}{c}
\Delta[n] \xrightarrow{\sigma} A \\
\downarrow \\
\Delta[3]_\text{eq} \star \Delta[n-2]
\end{array}
\]

along the map \(\Delta[n] \hookrightarrow \Delta[3]_\text{eq} \star \Delta[n-2]\) whose image includes the edge \(\{12\}\) of \(\Delta[3]_\text{eq}\) and all of the vertices of \(\Delta[n-2]\), or if it is the complicial companion of an \(n\)-simplex which admits such an extension.
The set of $n$-equivalences identified by Definition D.7.10 depends on the marked $(n + 1)$-simplices, which is the reason we have only stated this definition for an $n$-trivial complicial set. The $n$-equivalences in a generic complicial set are characterized by an inductive definition, the formulation of which we leave to the reader.

Finally, we introduce special terminology for those complicial sets that most closely represent $(\infty, n)$-categories.

D.7.11. Definition ($n$-complicial set). A marked simplicial set is an $n$-complicial set if and only if it is a complicial set that is $n$-trivial and saturated.

D.7.12. Example. For instance, by Exercise D.1.ii, the 0-complicial sets are precisely the Kan complexes, with their maximal marking. By Theorem D.4.13, the 1-complicial sets are precisely the quasi-categories, with their natural marking, which is the largest marking which makes a quasi-category into a complicial set.

D.7.13. Digression (the Verity model structure for $n$-complicial sets). The category of marked simplicial sets bears a cartesian closed, cofibrantly generated model structure whose fibrant objects are exactly the $n$-complicial sets and whose cofibrations are the monomorphisms, which is obtained as a left Bousfield localization of the model structure described in Digression D.1.17. In [125, §6.2-4] Verity describes a general paradigm for obtaining model structures that localize the model structure for complicial sets. The verification in this particular case is completed by Ozornova and Rovelli [86, 1.25].

The closure properties of complicial sets extend to saturated complicial sets and $n$-complicial sets. The proof, which appears in Corollary D.7.16, depends on two technical lemmas, the first and harder of which was first proven by Ozornova and Rovelli [86, B.5-6].

(i) \( \Delta[3]_{\text{eq}} \star \Delta[n] \hookrightarrow \Delta[3]^\# \star \Delta[n] \) \( \bigtimes (\partial \Delta[m] \hookrightarrow \Delta[m]) \) and

(ii) \( \Delta[3]_{\text{eq}} \star \Delta[n] \hookrightarrow \Delta[3]^\# \star \Delta[n] \) \( \bigtimes (\Delta[m] \hookrightarrow \Delta[m]) \)

are in the class of maps that is cellulary generated by the complicial anodynes together with the saturation extensions of Definition D.7.9.

Proof. When \( m = 0 \), the map considered in (i) above reduces to the inclusion \( \Delta[3]_{\text{eq}} \star \Delta[n] \hookrightarrow \Delta[3]^\# \star \Delta[n] \) which is one of the generating saturation extensions, so we may assume that \( m > 0 \). We begin by observing that the only \( k \)-simplices that are marked in the codomain of

\[
(\Delta[3]_{\text{eq}} \star \Delta[n]) \times \Delta[m] \cup_{(\Delta[3]_{\text{eq}} \star \Delta[n]) \times \partial \Delta[n]} (\Delta[3]^\# \star \Delta[n]) \times \partial \Delta[m] \hookrightarrow (\Delta[3]^\# \star \Delta[n]) \times \Delta[m]
\]

but not in the domain are \( k \)-simplices for \( m < k \leq n + 2 \) of the form

\[
\Delta[1] \star \Delta[k - 2] \xrightarrow{(y \star \alpha, \beta)} (\Delta[3]_{\text{eq}} \star \Delta[n]) \times \Delta[m]
\]

where

- \( y \) is one of the four edges \( \{01\}, \{12\}, \{23\}, \{03\} \) of \( \Delta[3]_{\text{eq}} \),
- \( \alpha: \Delta[k - 2] \hookrightarrow \Delta[n] \) is injective, and
- \( \beta: \Delta[k] \twoheadrightarrow \Delta[m] \) is surjective.
These conditions explain the bounds on \( k \) given above.

Since \( \beta: [k] \rightarrow [m] \) is surjective and order-preserving, \( \beta(0) = 0 \) and \( \beta(1) \) equals either 0 or 1. We factor the inclusion as a sequence of two pushouts

\[
\begin{array}{c}
\coprod \Delta[3]_{eq} \ast \Delta[k-2] \xrightarrow{(id \ast b_0)} (\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m] \cup (\Delta[3]_{eq} \ast \Delta[n]) \times \partial \Delta[m] \\
\coprod \Delta[3] \ast \Delta[k] \xrightarrow{r} \bullet \\
\end{array}
\]

where the left-hand coproduct is over all pairs \((\alpha, \beta)\) as above with \( \beta(1) = 0 \) and the right-hand coproduct is over all triples \((\gamma, \alpha, \beta)\) with \( \beta(1) = 1 \). A detailed argument that the pair of attaching maps preserves the required marked simplices is given in [86, B.5].

For the map considered in (i), observe that the only simplices that are marked in the codomain of

\[
(\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m] \cup (\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m] 
\]

but not in the domain are \( m \)-simplices

\[
\Delta[1] \ast \Delta[m - 2] \xrightarrow{(\gamma \ast \alpha, id)} (\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m]
\]

where

- \( \gamma \) is one of the four edges \( \{01, 12, 23, 03\} \) of \( \Delta[3]_{eq} \) and
- \( \alpha: \Delta[m - 2] \rightarrow \Delta[n] \) is injective,

which implies that we must have \( m - 2 \leq n \). To mark the simplices \((\gamma \ast \alpha, id)\) we take a pushout along a suitable complicial thinness extension:

\[
\begin{array}{c}
\coprod \Delta^1[m + 1] \xrightarrow{(id \ast b_0)} (\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m] \cup (\Delta[3]_{eq} \ast \Delta[n]) \times \Delta[m] \\
\coprod \Delta^1[m + 1] \xrightarrow{r} (\Delta[3] \ast \Delta[n]) \times \Delta[m]
\end{array}
\]

where the coproduct is over all unmarked \( m \)-simplices \((\gamma \ast \alpha, id)\). A detailed argument that the attaching map preserves the required marked simplices is given in [86, B.6]. This completes the verification that the two Leibniz products are in the saturated class generated by the complicial anodyne extensions and the saturation maps. \(\square\)

**D.7.15. Lemma.** The Leibniz joins

(i) \((\Delta[3]_{eq} \ast \Delta[n]) \ast (\Delta[3] \ast \Delta[n]) \rightarrow (\Delta[3] \ast \Delta[n]) \ast (\Delta[3]_{eq} \ast \Delta[n]) \rightarrow \Delta[m]\),

(ii) \((\Delta[3] \ast \Delta[n]) \ast (\Delta[3]_{eq} \ast \Delta[n]) \rightarrow (\Delta[3]_{eq} \ast \Delta[n]) \ast (\Delta[3] \ast \Delta[n])\),

(iii) \((\Delta[3]_{eq} \ast \Delta[n]) \ast (\Delta[3] \ast \Delta[n]) \rightarrow (\Delta[3]_{eq} \ast \Delta[n]) \ast (\Delta[3] \ast \Delta[n])\), and

(iv) \((\Delta[3] \ast \Delta[n]) \ast (\Delta[3]_{eq} \ast \Delta[n]) \rightarrow (\Delta[3] \ast \Delta[n]) \ast (\Delta[3]_{eq} \ast \Delta[n])\)
are in the class of maps that is cellularly generated by the complicial anodyne extensions together with the saturation extensions of Definition D.7.9.

**Proof.** The Leibniz join considered in (i) is evidently a pushout

\[
\begin{array}{ccc}
\Delta[3]_{eq} \star \Delta[n] \star \Delta[m] & \xrightarrow{id} & \Delta[3]_{eq} \star \Delta[n] \star \Delta[m] \cup \Delta[3]^\# \star \Delta[n] \star \partial \Delta[m] \\
\downarrow & & \downarrow \\
\Delta[3]^\# \star \Delta[n] \star \Delta[m] & \xrightarrow{id} & \Delta[3]^\# \star \Delta[n] \star \Delta[m]
\end{array}
\]

of a generating saturation extension. Similarly, the Leibniz join considered in (ii) is evidently a pushout of the saturation extension

\[
\Delta[m] \star \Delta[3]_{eq} \star \Delta[n] \xhookleftarrow{e} \Delta[m] \star \Delta[3]^\# \star \Delta[n].
\]

The Leibniz join

\[
\Delta[3]_{eq} \star \Delta[n] \star \Delta[m], \cup \Delta[3]^\# \star \Delta[n] \star \Delta[m] \longrightarrow \Delta[3]^\# \star \Delta[n] \star \Delta[m],
\]

considered in (iii) is the identity (and not just entire), as is the Leibniz join considered in (iv). \(\square\)

Lemmas D.7.14 and D.7.15 enable us to expeditiously prove the following result, extending Corollary D.3.13.

**D.7.16. Corollary.**

(i) For any saturated complicial set \(A\) and marked simplicial set, \(A^X\) is again a saturated complicial set.

(ii) For any \(n\)-complicial set \(A\) and marked simplicial set, \(A^X\) is again an \(n\)-complicial set.

(iii) For any complicial set \(A\) and map of marked simplicial sets \(f : X \to A\), the marked slices \(A_{/f}\) and \(f_{/A}\) are complicial sets. Moreover, for any complicial isofibration \(p : A \to B\) of complicial sets, any monomorphism of marked simplicial sets \(i : X \to Y\), and any map \(f : Y \to A\), the Leibniz marked slices

\[
A_{/f} \to A_{/fi} \times B_{/pf} \quad \text{and} \quad f_{/A} \to f_{/fi} A \times p_{/B} f_{/B}
\]

are complicial isofibrations.

(iv) For any saturated complicial set \(A\) and map of marked simplicial sets \(f : X \to A\), the marked slices \(A_{/f}\) and \(f_{/A}\) are saturated complicial sets.

(v) For any \(n\)-complicial set \(A\) and map of marked simplicial sets \(f : X \to A\), the marked slices \(A_{/f}\) and \(f_{/A}\) are \(n\)-complicial sets.

**Proof.** The analogue of (i) and (ii) for a complicial set \(A\) is proven in Corollary D.3.13, so we pick up where that argument left off. In light of Definition D.7.9, (i) follows immediately from Lemma D.7.14. To extend this result to prove (ii), we need only verify that we may solve lifting problems

\[
\begin{array}{ccc}
\Delta[m] \times X & \xrightarrow{} & A \\
\downarrow & & \downarrow \\
\Delta[m]_r \times X
\end{array}
\]
for $m > n$ under the hypothesis that $A$ is an $n$-trivial saturated complicial set. On account of the pushout diagram

$$\coprod_{\sigma \in tX_m} \Delta[m] \overset{(id,\sigma)}{\longrightarrow} \Delta[m] \times X \longrightarrow A$$

where the coproduct is over the set of thin $m$-simplices in $X$, this is clear.

The final three statements refer to the marked slices defined by Lemma D.2.20. Lemma D.2.19 proves (iii), while this result combines with Lemma D.7.15 to prove (iv). For the final statement (iv), we need to verify that if $A$ is $n$-trivial, then the lifting problems

$$\Delta[m] \star X \longrightarrow A \quad X \star \Delta[m] \longrightarrow A$$

$$\coprod_{\sigma \in tX_m} \Delta[m]_t \star X \longrightarrow \Delta[m]_t \times X$$

where the coproduct is over the set of thin $m$-simplices in $X$, this is clear.

D.7.i. Exercise ([125, 25]). Prove Lemma D.7.5.

D.7.ii. Exercise. Find another example of a complicial set whose $n$-trivialization is no longer a complicial set.
APPENDIX E

∞-Cosmoi Found in Nature

In this chapter, we establish concrete examples of ∞-cosmoi found in nature. Typically, the objects of these ∞-cosmoi are infinite-dimensional categories as instantiated by some particular non-algebraic model and the functors between them are also morphisms of such. In most cases, there is an accompanying model structure known to the higher categories literature which lends us appropriate classes of isofibrations, equivalences, and trivial fibrations. After indicating where a proof of the existence of a suitable model structure may be found, the only work that remains for us is to transfer the enrichment discussed in the model category literature to an enrichment over Joyal’s model structure for quasi-categories on simplicial sets.

The general theory of what we might call “quasi-categorically enriched model categories” is discussed in §E.1. In particular, we prove that any “quasi-categorically enriched category of fibrant objects” — a combination of Definitions C.1.1 and C.3.11 — defines an ∞-cosmos and describe a change-of-base result that helps produce examples.

In §E.2, we apply these results to establish the familiar ∞-cosmoi of (∞, 1)-categories defined using the complete Segal space, Segal categories, and 1-complicial set models. We also prove that the change-of-model functors displayed in (10.0.1) define cosmological biequivalences to and from the ∞-cosmos of quasi-categories.

Finally, in §E.3, we turn our attention to what might be called higher ∞-categories, establishing ∞-cosmoi whose objects are (∞, 𝑛)- or even (∞, ∞)-categories in some model.

E.1. Quasi-Categorically Enriched Model Categories

Many examples of ∞-cosmoi arise as categories of fibrant objects in a model category that is enriched over Joyal’s model structure simplicial sets—at least if all fibrant objects are cofibrant as is surprisingly often the case.¹ For example, the ∞-cosmos of quasi-categories itself arises in this manner, as Joyal’s model structure, described in in Digression 1.1.30, is cartesian closed. The fibrant objects in the Joyal model structure are exactly the quasi-categories, the fibrations between fibrant objects are precisely the isofibrations between quasi-categories of Definition 1.1.17, and the weak equivalences between fibrant objects are exactly the equivalences of quasi-categories of Definition 1.1.22.

E.1.1. Proposition (∞-cosmoi presented by a Joyal-enriched model category). Let ℳ be any model category that is enriched over the Joyal model structure and in which every fibrant object is cofibrant. Then the full subcategory of fibrant objects ℳ_f inherits the structure of an ∞-cosmos in which the isofibrations are the fibrations between fibrant objects, the equivalences are the weak equivalences between fibrant objects, and the trivial fibrations are the trivial fibrations between fibrant objects.

Proof. Since the fibrant objects in ℳ are also cofibrant, Lemma C.3.12 implies the simplicially enriched homs between fibrant-cofibrant objects of ℳ are quasi-categories, which we denote by

¹This hypothesis, that all fibrant objects are cofibrant, is not essential for the development of ∞-category theory. Indeed, the first definition of an “∞-cosmos” to appear in the literature did not include this requirement [106].
Fun(A, B). The same result also implies that for any fibration \( f: A \twoheadrightarrow B \) between fibrant objects, the induced map \( f_*: \text{Fun}(X, A) \twoheadrightarrow \text{Fun}(X, B) \) is an isofibration of quasi-categories.

By Example C.1.4, the fibrant objects and fibrations and weak equivalences between them define a category of fibrant objects in the sense of Definition C.1.1. In particular, the unenriched category \( \mathcal{M}_f \) possesses a terminal object, small products, pullbacks of isofibrations, and limits of countable towers of isofibrations, with each of these limits created in \( \mathcal{M} \). Since \( \mathcal{M} \) admits simplicial cotensors, Proposition A.5.5 implies that these 1-categorical limits are conical, and thus \( \mathcal{M}_f \) possesses the conical limits of axiom 1.2.1(i). The stability of the isofibrations under the 1-categorical limits of axiom 1.2.1(ii) then is also part of the category of fibrant objects structure of Example C.1.4, though in many instances the stability of the class of isofibrations can also be established via Lemma C.2.3.

It remains to verify the axioms concerning the simplicial cotensors. By hypothesis \( \mathcal{M} \) is also cotensored over simplicial sets, and since \( \mathcal{M} \) is an enriched model category, the cotensor bifunctor is a right adjoint of a Quillen two-variable adjunction. Directly from the defining axiom of Definition C.3.8, the fibrant objects are closed under cotensor with cofibrant objects, but since all objects in the Joyal model structure are cofibrant, the fibrant objects are closed under simplicial cotensors. Thus \( \mathcal{M}_f \) possesses all the limits of 1.2.1(i). Leibniz stability a special case of Definition C.3.8, and thus all the required axioms have been verified.

Furthermore:

E.1.2. COROLLARY. Any right Quillen simplicially enriched right adjoint between quasi-categorically enriched model categories with all fibrant objects cofibrant defines a cosmological functor that is a cosmological biequivalence whenever the Quillen adjoint defines a Quillen equivalence.

PROOF. A Quillen right adjoint preserves fibrant objects, so a simplicially enriched right Quillen adjoint defines a simplicial functor between the subcategories of fibrant objects, satisfying the first requirement of a cosmological functor. As a right Quillen functor, it preserves fibrations between fibrant objects, and thus preserves the isofibrations in the \( \infty \)-cosmoi defined by Proposition E.1.1. Finally, a simplicially enriched right adjoint preserves both conical and weighted limits, by Proposition A.6.21. This verifies all of the axioms defining a cosmological functor.

Now consider a simplicially enriched right Quillen equivalence \( U: \mathcal{N} \rightarrow \mathcal{M} \), with left adjoint \( F \). The action of homs of the functor \( U \) is isomorphic to the map defined by precomposition with a counit component:

\[
\mathcal{N}(X, Y) \xrightarrow{U_{X,Y}} \mathcal{M}(UX, UY) \xrightarrow{- \circ \varepsilon_X} \mathcal{N}(FU_{X}, Y)
\]

where the displayed vertical isomorphism is adjoint transposition. By Lemma C.3.6, the counit component \( \varepsilon_X \) is a weak equivalence when \( X \) is fibrant. When \( Y \) is fibrant, the functor \( \mathcal{N}(\_ , Y): \mathcal{N}^{\text{op}} \rightarrow \text{sSet} \) is right Quillen by the dual of Exercise C.3.iii applied to the Quillen two-variable adjunction of Definition C.3.11. Hence, by Lemma C.3.4, this functor carries weak equivalences between cofibrant objects in \( \mathcal{N} \) to equivalences between quasi-categories. Putting this all together, we see that when \( X \) and \( Y \) are fibrant, the diagonal map defines an equivalence of quasi-categories, and thus \( U_{X,Y}: \mathcal{N}(X, Y) \rightarrow \mathcal{M}(UX, UY) \) must be an equivalence of quasi-categories as well. This verifies the local equivalence property of cosmological biequivalences.  

584
Essential surjectivity is also a consequence of Lemma C.3.6, which supplies a weak equivalence \( M \Rightarrow URFM \) for any fibrant object \( M \in \mathcal{N} \) defined by the derived unit. Since \( RFM \) is a fibrant object in \( \mathcal{N} \), this defines an equivalence in the \( \infty \)-cosmos \( \mathcal{M}_f \) involving an object in the image of \( U: \mathcal{N}_f \rightarrow \mathcal{M}_f \), as required.

With Proposition E.1.1 in hand, the next question is where do model categories enriched over the Joyal model structure come from? Unsurprisingly, this question has not attracted much attention in the literature, but the mathematical community has done us a considerable favor, in many cases, by providing model categories of infinite-dimensional categories that are enriched over some other cartesian closed model category. Our strategy will be to apply Theorem C.3.16 to convert a known enrichment to an enrichment over Joyal’s model structure for quasi-categories. Combining that result with Proposition E.1.1, we obtain a useful change-of-base result that produces model categories enriched over the Joyal model structure.

**E.1.3. Proposition.** Let \( \mathcal{V} \) be a cartesian closed model category equipped with a Quillen adjunction

\[
\begin{array}{ccc}
\mathsf{sSet} & \xrightarrow{F} & \mathcal{V} \\
\circlearrowright & \downarrow U & \\
\mathcal{V} & \xleftarrow{U} & \mathsf{sSet}
\end{array}
\]

whose right adjoint is valued in the Joyal model structure and whose left adjoint preserves finite products.

(i) Then for any \( \mathcal{V} \)-model category \( \mathcal{M} \) in which every fibrant object is cofibrant, the full subcategory of fibrant objects \( \mathcal{M}_f \) defines an \( \infty \)-cosmos in which the isofibrations are the fibrations between fibrant objects, the equivalences are the weak equivalences between fibrant objects, the trivial fibrations are the trivial fibrations between fibrant objects, the functor spaces are defined by \( \text{Fun}(M, N) := UM(M, N) \), where \( M(M, N) \) is the hom-object in \( \mathcal{V} \), and the simplicial cotensor of \( M \in \mathcal{M}_f \) with \( S \in \mathsf{sSet} \) are defined by the \( \mathcal{V} \)-cotensor \( M^S \).

(ii) Moreover, any right Quillen \( \mathcal{V} \)-adjoint between \( \mathcal{V} \)-model categories of this form defines a cosmological functor that is a cosmological biequivalence whenever the Quillen adjoint is a Quillen equivalence.

**Proof.** The adjunction \( F \dashv U \) is assumed to be Quillen adjunction between cartesian closed model categories in which the left adjoint preserves finite products. Thus, by Theorem C.3.16, any \( \mathcal{V} \)-model category \( \mathcal{M} \) admits the structure of a model category enriched over the Joyal model structure with the same underlying unenriched model category with enriched homs and cotensors defined by:

\[
\text{Fun}(M, N) := UM(M, N) \quad \text{and} \quad M^S := M^{FS},
\]

as claimed. Since the underlying model category is unchanged, every fibrant object in \( \mathcal{M} \) is still cofibrant. Thus, by Proposition E.1.1, the full subcategory of fibrant objects defines an \( \infty \)-cosmos.

Again because the change-of-base result does not affect the underlying model categories, any right Quillen adjoint between \( \mathcal{V} \)-model categories remains a right Quillen adjoint. By Proposition A.7.3, a \( \mathcal{V} \)-functor becomes a simplicially enriched functor under the new enrichments. Corollary E.1.2 now tells us that a right Quillen \( \mathcal{V} \)-adjoint gives rise to a cosmological functor that is a cosmological biequivalence when that Quillen adjoint is a Quillen equivalence.

We often make use of this result in the following special case:
E.1.4. COROLLARY. Let \( \mathcal{V} \) be a cartesian closed model category in which all fibrant objects are cofibrant that is equipped with a Quillen adjunction

\[
\begin{array}{ccc}
\text{sSet} & \xleftarrow{F} & \mathcal{V} \\
\downarrow & \searrow \downarrow \nearrow \uparrow & \ \\
\uparrow & \rightarrow \uparrow \leftarrow & \ U
\end{array}
\]

whose right adjoint is valued in the Joyal model structure and whose left adjoint preserves finite products. Then the fibrant objects of \( \mathcal{V} \) define a cartesian closed \( \infty \)-cosmos \( \mathcal{V}_f \) and the right adjoint defines a cosmological functor \( U: \mathcal{V}_f \to \mathcal{QC} \) that is naturally isomorphic to the underlying quasi-category functor and is a cosmological biequivalence whenever \( U \) is a Quillen equivalence.

**Proof.** When the fibrant objects of \( \mathcal{V} \) are cofibrant, \( \mathcal{V} \) itself satisfies the hypotheses of Proposition E.1.3(i) and thus \( \mathcal{V}_f \) defines an \( \infty \)-cosmos. By Lemma A.7.8, \( F \to U \) defines a simplicially enriched adjunction between simplicial sets and the simplicially enriched category \( U_\ast \mathcal{V} \), so in this way we obtain a simplicially enriched right Quillen functor \( U: U_\ast \mathcal{V} \to \text{sSet} \) between model categories enriched over the Joyal model structure. By Corollary E.1.2, \( U \) then defines a cosmological functor \( U: \mathcal{V}_f \to \mathcal{QC} \). Combining Remark A.1.9 with the definition of the functor spaces of \( \mathcal{V}_f \) given in Proposition E.1.3, we obtain the following natural isomorphism for any \( X \in \mathcal{V}_f \)

\[
U(X) \cong U(X^1) \cong \text{Fun}(1, X)
\]

proving that the cosmological functor \( U: \mathcal{V}_f \to \mathcal{QC} \) is naturally isomorphic to the underlying quasi-category functor associated to the \( \infty \)-cosmos \( \mathcal{V}_f \); see also Remark 1.3.8. \( \square \)

Proposition E.1.3 inspires the following trivial examples of \( \infty \)-cosmoi.

E.1.5. EXAMPLE (1-categories as \( \infty \)-cosmoi). Any complete locally small 1-category \( \mathcal{C} \) can be made into an \( \infty \)-cosmos in which \( \text{Fun}(A, B) \) is just the set of morphisms from \( A \) to \( B \). By the Yoneda lemma, the equivalences are then the isomorphisms in \( \mathcal{C} \) and so by Lemma 1.2.16 all maps must necessarily be isofibrations. The cotensor of an object \( A \in \mathcal{C} \) with a simplicial set \( S \) is defined by

\[
A^S := A^{\pi_0 S} := \prod_{\pi_0 S} A.
\]

Ignoring the fact that model categories are typically assumed to have colimits as well as limits, this construction can be seen as a special case of Proposition E.1.3 applied to the adjunction

\[
\begin{array}{ccc}
\text{sSet} & \xleftarrow{\pi_0} & \text{Set} \\
\downarrow & \searrow \downarrow \nearrow \uparrow & \ \\
\uparrow & \rightarrow \uparrow \leftarrow & \text{sk}_0
\end{array}
\]

whose right adjoint embeds \( \text{Set} \hookrightarrow \text{sSet} \) as the subcategory of 0-skeletal simplicial sets; see Definition C.5.2. Here the cartesian closed model structure on \( \text{Set} \) is not the one considered in Exercise C.3.iv but rather the one in which the weak equivalences are the isomorphisms and all maps are taken to be both cofibrations and fibrations. To see that this adjunction is Quillen, note that \( \pi_0 \) vacuously preserves cofibrations, while \( \text{sk}_0 \) carries any map to an isofibration of quasi-categories: This latter claim follows by adjunction since the defining lifting-properties below-left transpose to the lifting...
Famously, $\pi_0$ preserves finite products, so the conditions of change-of-base theorem apply. The homotopy 2-category of an $\infty$-cosmos arising in this way will have no non-identity 2-cells.

E.1.6. Example (2-categories as $\infty$-cosmoi). Categorifying the previous example, any 2-category $C$ with sufficient limits defines an $\infty$-cosmos where $\text{Fun}(A, B)$ is the nerve of the hom-category of morphisms from $A$ to $B$ in $C$. By Theorem 1.4.7, the equivalences are necessarily the equivalences in the 2-category. Inspired by Proposition 1.4.10, we take the isofibrations to be the isofibrations in the 2-category.

Interpreting “sufficient limits” to mean the limits of axiom 1.2.1(i), the remaining axiom 1.2.1(ii) can be verified by hand. Alternatively, again ignoring the fact that model categories are typically assumed to have colimits as well as limits, we may apply Proposition E.1.3 to the homotopy category $\dashv$ nerve adjunction

$$s\text{Set} \leftrightarrow \text{Cat}$$

of Proposition 1.1.11, which is a Quillen adjunction between Joyal’s model structure and the usual “folk” model structure on categories. Any 2-category admitting suitable finite limits and colimits is canonically enriched over the folk model structure on categories, when it is given the “trivial” $\text{Cat}$-enriched model structure described by Lack [70], with weak equivalences and fibrations are exactly the equivalences and isofibrations just described.

It remains to unpack the meaning of the weaselly phrase “sufficient limits.” By Proposition 6.3.1, the 2-category $C$ is required to have all PIE-limits, that is 2-categorical products, inserters, and equifiers discussed in Digression 6.2.7. This implies that $C$ admits pseudopullbacks of all maps, by the construction of Definition 6.3.3, but this doesn’t quite imply that $C$ admits 2-pullbacks of isofibrations. Instead, the proof of Lemma 6.3.7 constructs a bipullback of an isofibration, with the usual hom-category isomorphism replaced by a hom-category equivalence. Similar remarks apply to limits of towers of isofibrations. But in practice, the 2-categories that admit PIE limits such as those considered in [17] do seem to admit 2-pullbacks of isofibrations and 2-limits of towers of isofibrations and thus define examples of $\infty$-cosmoi.

In particular, Example E.1.6 specializes to recover the $\infty$-cosmos structure on $\text{Cat}$ discussed in Proposition 1.2.11. Intriguingly, it also defines an $\infty$-cosmos structure on $\text{Cat}^{\text{opp}}$ in which the “isofibrations” are those functors that are injective on objects.\footnote{In the “folk” model structure on $\text{Cat}$, the fibrations are the isofibrations, the weak equivalences are the equivalences, and the cofibrations are the injective-on-objects functors. Injective-on-objects functors satisfy an isomorphism extension property dual to the isomorphism lifting property that defines the 2-category notion of isofibration.} Combining these observations with the dual $\infty$-cosmos construction of Definition 1.2.25, we see that the four 2-categorical duals $\text{Cat}$, $\text{Cat}^{\text{opp}}$, $\text{Cat}^{\text{co}}$, and $\text{Cat}^{\text{coop}}$ are all $\infty$-cosmoi.

The $\infty$-cosmoi of Example E.1.6 admit an abstract characterization as those $\infty$-cosmoi that are isomorphic (as quasi-categorically enriched categories) to their homotopy 2-categories. In this case,
the weak 2-limits of Chapter 3 are actually strict and many of our results specialize to known theorems in the 2-categorical literature.

E.1.7. Example (simplicial model categories as $\infty$-cosmoi). The identity functor $\text{id} : s\text{Set} \to s\text{Set}$ defines a right Quillen adjoint from Quillen’s model structure for Kan complexes to Joyal’s model structure for quasi-categories; evidently its left adjoint preserves products. Hence, any Kan complex enriched model category—or simplicial model category in the usual parlance—may be regarded as a quasi-categorically enriched model category in which each of the mapping-spaces between fibrant-cofibrant objects happens to be a Kan complex. Thus, any simplicial model category whose fibrant objects are cofibrant may be regarded as presenting an $\infty$-cosmos.

The homotopy 2-categories of $\infty$-cosmoi arising in this manner are all $(2,1)$-categories, with every natural transformation defining a natural isomorphism.

Exercises.

E.1.i. Exercise. State and prove a version of Proposition E.1.3 that applies to enriched categories of fibrant objects, such as considered in Examples E.1.5 and E.1.6, that may admit few colimits.

E.2. $\infty$-Cosmoi of $(\infty,1)$-Categories

The $\infty$-cosmos for quasi-categories was introduced in Proposition 1.2.10. In this section, we establish three other $\infty$-cosmoi whose objects define $(\infty,1)$-categories in some model and construct the biequivalences between them displayed in (10.0.1):

\[
\begin{align*}
\text{CSS} & \xrightarrow{\text{disc}} \text{Segal} \\
\downarrow_{\text{nerve}} & \quad \quad \downarrow_{\text{nerve}} \\
\text{QC}a & \quad \text{Comp}
\end{align*}
\]

A complete Segal space, as defined by Charles Rezk in [95], is firstly a bisimplicial set $X \in \text{Set}^{\Delta^\text{op} \times \Delta^\text{op}}$, where we regard $X_{m,n}$ as the set of $n$-simplices in the $m$th space of a simplicial space $X_\bullet \in s\text{Set}^{\Delta^\text{op}}$. It is conventional to regard the simplicial sets $X_m = X_{m,\bullet}$ as the “columns” of the bisimplicial set $X$, while the simplicial sets $X_{\bullet,n}$ define the “rows.”

Before giving the formal definition of a complete Segal space, we explain the idea. In a complete Segal space, the diagram

\[
\begin{align*}
X_0 & \xrightarrow{\sim} X_1 & X_1 & \xrightarrow{\sim} X_2 & \ldots \\
\downarrow & \quad \quad \downarrow & \quad \quad \downarrow & \quad \quad \downarrow & \quad \quad \downarrow \\
X_1 & \xleftarrow{\sim} X_2 & X_2 & \xleftarrow{\sim} X_3 & \ldots
\end{align*}
\]

defines a simplicial object in the category of Kan complexes. Moreover, for each $m \geq 0$, the map $X_m \to M_n X$ whose codomain is the space of “boundary data” associated with the $m$-simplex is a Kan fibration. The spaces $X_0$ and $X_1$ are the “spaces of objects and arrows” for the complete Segal space. The so-called “Segal condition” implies that the space $X_n$ may be regarded as the “space of $n$-composable arrows.” A Segal space, satisfying the conditions enumerated thus far, is then something like a “category object up to homotopy.” The final “completeness” condition relates the spatial structure
of $X_0$ with the categorical structure just defined, expressing the idea that paths in $X_0$ should correspond to isomorphisms in $X_\bullet$.

The formal definition of a complete Segal space has three conditions, which are most easily described in terms of the weighted limit bifunctor
\[(\text{Set}^{\Delta^{op}})^{op} \times \text{sSet}^{\Delta^{op}} \xrightarrow{\lim_{\Delta^{op}}} \text{sSet}\]

where $\text{sSet}$ is regarded as a $\text{Set}$-enriched category. Note that the weights for $\Delta^{op}$-indexed diagrams in $\text{sSet}$ are $\Delta^{op}$-indexed diagrams in $\text{Set}$, i.e., simplicial sets. In more detail:

E.2.1. DEFINITION (complete Segal space).

(i) A simplicial object $X_\bullet \in \text{sSet}^{\Delta^{op}}$ is Reedy fibrant just when the induced map on weighted limits

\[X_m \cong \lim_{\Delta[m]} X \to \lim_{\partial \Delta[m]} X =: M_m X\]

is a Kan fibration of simplicial sets for all $m \geq 0$.

(ii) A Reedy fibrant simplicial object $X_\bullet$ is a Segal space just when the induced map on weighted limits

\[X_n \cong \lim_{\Delta[n]} X \to \lim_{\Lambda^k[n]} X\]

is a trivial fibration of simplicial sets for all $n \geq 2$ and $0 < k < n$.

(iii) A Segal space $X_\bullet$ is a complete Segal space, just when the induced map on weighted limits

\[\lim_{\mathbb{I}} X \to \lim_{\Delta[0]} X \cong X_0\]

is a trivial fibration of simplicial sets, asserting that the “space of isomorphisms in $X_\bullet$” is equivalent to the space $X_0$.

The category of bisimplicial sets, as a presheaf category, is cartesian closed and hence enriched over itself. Among the great supply of product-preserving functors $\text{Set}^{\Delta^{op} \times \Delta^{op}} \to \text{Set}^{\Delta^{op}}$ that may be used to convert this to a simplicial enrichment, there are two of particular interest: column $0 : \text{Set}^{\Delta^{op} \times \Delta^{op}} \to \text{Set}^{\Delta^{op}}$, which sends a bisimplicial set $X$ to its space $X_0$ of 0-simplices and row $0 : \text{Set}^{\Delta^{op} \times \Delta^{op}} \to \text{Set}^{\Delta^{op}}$, which passes to set the set of vertices in each space in the simplicial object. As observed by Joyal and Tierney [62], the former construction carries a complete Segal space to a Kan complex, while the latter construction carries a complete Segal space to a quasi-category and will be used to prove:

³By Reedy fibrancy, the induced map is already a Kan fibration, so to demand that it is a trivial fibration is equivalent to demanding that it is a weak homotopy equivalence. A priori, this definition is stronger than the usual Segal condition, which requires that the map induced on weighted limits by the inclusion of the spine of the $n$-simplex for each $n \geq 2$ is a trivial fibration. The spine inclusions are in the class cellularly generated by the inner horn inclusions, so by Exercise C.2.v applied to the two-variable adjunction involving the weighted limit, our condition clearly implies the classical Segal condition. The proof of the converse is more subtle and can be found as [62, 3.4].

⁴Other choices of weight may be used to define the “space of isomorphisms” such as the colimit of the diagram

\[
\Delta[2] \xleftarrow{\partial} \Delta[1] \xrightarrow{\partial} \Delta[2]
\]

See [95, §11] for a discussion.

⁵By the 2-of-3 property, this is equivalent to the arguably more natural condition that the map $\Delta : X_0 \to \lim_{\mathbb{I}} X$, induced by $! : \mathbb{I} \to \Delta[0]$ is a weak homotopy equivalence.
E.2.2. PROPOSITION. The full subcategory $\text{CSS} \hookrightarrow \text{Set}^{\Delta^{op} \times \Delta^{op}}$ defines a cartesian closed $\infty$-cosmos in which the functor space $\text{Fun}(A, B)$ is defined to be the underlying quasi-category, formed by the vertices in each internal hom $B^A$. With respect to this $\infty$-cosmos structure:

(i) The underlying quasi-category functor $(-)_0 := \text{row}_0 : \text{CSS} \Rightarrow \text{QCat}$ is a cosmological biequivalence.

(ii) There is a second cosmological biequivalence $\text{nerve} : \text{QCat} \rightarrow \text{CSS}$, which carries a quasi-category $A$ to the bisimplicial set whose $(m, n)$-simplices are simplicial maps $\Delta[m] \times \Delta[n] \rightarrow A$ indexed by the product of the ordinal category with the ordinal groupoid.

PROOF. By a theorem of Rezk, the complete Segal spaces form the fibrant objects in a cartesian closed model structure borne by the category of bisimplicial sets in which all objects are cofibrant [95]. Precomposition with the adjoint pair of functors defined by $\pi_1([m] \times [n]) := [m]$ and $\iota_0([m]) := [m] \times [0]$ induces an adjunction as below-right:

$$
\Delta \quad \perp \quad \Delta \times \Delta \quad \sim \quad \text{Set}^{\Delta^{op}} \quad \perp \quad \text{Set}^{\Delta^{op} \times \Delta^{op}}
$$

(E.2.3)

Joyal and Tierney prove that this pair of functors defines a Quillen equivalence between the model structure for quasi-categories and the model structure for complete Segal spaces [62, 4.11]. By inspection, the left adjoint preserves finite products, so Corollary E.1.4 applies to create a cartesian closed $\infty$-cosmos structure on the full subcategory $\text{CSS}$, as detailed in Proposition E.1.3, for which $(-)_0 := \text{row}_0 := \iota_0^*$ is a cosmological biequivalence.

A second adjunction between simplicial sets and bisimplicial sets pointing in the opposite direction has a left adjoint defined as the left Kan extension of the functor

$$
\Delta \times \Delta \quad \to \quad \text{Set}^{\Delta^{op}}
$$

$$
[m] \times [n] \quad \mapsto \quad \Delta[m] \times \Delta[n]
$$

along the Yoneda embedding $\Delta \times \Delta \hookrightarrow \text{Set}^{\Delta^{op} \times \Delta^{op}}$; here $\Delta[n]$ is the nerve of the groupoid with $n + 1$ objects and one exactly morphism in each hom-set, obtained by freely inverting the morphisms in the ordinal category $\mathbb{N} + 1$. The right adjoint is the corresponding “nerve” functor described in the statement of (ii). Exploiting it, Joyal and Tierney also prove that the adjunction

$$
\text{Set}^{\Delta^{op} \times \Delta^{op}} \quad \perp \quad \text{Set}^{\Delta^{op}}
$$

is a Quillen equivalence with respect to the model structures for complete Segal spaces and quasi-categories [62, 4.12]. To conclude from Corollary E.1.2 that $\text{nerve} : \text{QCat} \rightarrow \text{CSS}$ is a cosmological biequivalence it remains only to show that this functor is simplicially enriched and preserves simplicial cotensors, or equivalently, by Proposition A.4.6, that the adjunction $\text{lan} \dashv \text{nerve}$ is simplicially enriched.
To verify this, we make use of the external product bifunctor:

\[
\mathcal{S}et^{\Delta^\text{op}} \times \mathcal{S}et^{\Delta^\text{op}} \to \mathcal{S}et^{\Delta^\text{op} \times \Delta^\text{op}}
\]

\[
(A, B) \mapsto (A \Box B)_{m,n} := A_m \times B_n
\]

Since any bisimplicial set \( X \) may be recovered as a canonical colimit of representables, which the left adjoint of course preserves, it suffices to consider maps from a representable bisimplicial set \( \Delta[m] \Box \Delta[n] \) to a simplicial set \( A \). In the simplicial enrichment of \( \mathcal{S}et^{\Delta^\text{op} \times \Delta^\text{op}} \) just defined, the simplicial set of maps from \( \Delta[m] \Box \Delta[n] \) to \( \text{nerve}(A) \) has \( k \)-simplices defined to be the set of \((k, 0)\)-simplices in the bisimplicial set \( \text{nerve}(A) \Delta[m] \Box \Delta[n] \). Now

\[
(\text{nerve}(A) \Delta[m] \Box \Delta[n])_{k,0} := \mathcal{S}et^{\Delta^\text{op} \times \Delta^\text{op}}((\Delta[m] \Box \Delta[k]), \text{nerve}(A))
\]

by the definition of the cartesian closed structure on bisimplicial sets

\[
\cong \mathcal{S}et^{\Delta^\text{op} \times \Delta^\text{op}}((\Delta[m] \times \Delta[k]) \Box \Delta[n], \text{nerve}(A))
\]

by the definition of the external product

\[
\cong \mathcal{S}et^{\Delta^\text{op}}(\text{lan}((\Delta[m] \times \Delta[k]) \Box \Delta[n]), A)
\]

by adjunction. Joyal and Tierney prove in [62, 2.11] that the left Kan extension acts on the external tensor product by \( \text{lan}(B \Box \Delta[n]) \cong B \times \Delta[n] \). So we have

\[
\cong \mathcal{S}et^{\Delta^\text{op}}((\Delta[m] \times \Delta[k]) \times \Delta[n], A)
\]

\[
\cong \mathcal{S}et^{\Delta^\text{op}}((\Delta[m] \times \Delta[n]) \times \Delta[k], A)
\]

\[
\cong \mathcal{S}et^{\Delta^\text{op}}(\text{lan}(\Delta[m] \Box \Delta[n]) \times \Delta[k], A)
\]

\[
\cong \mathcal{S}et^{\Delta^\text{op}}(\text{lan}(\Delta[m] \Box \Delta[n]) \times \Delta[k], A)
\]

by the definition of the cartesian closed structure on simplicial sets. This proves that the adjunction is compatible with the simplicial enrichments, so it follows from Corollary E.1.2 and [62, 4.12] that \( \text{nerve}: \mathcal{Q}Cat \to \mathcal{CSS} \) is a cosmological biequivalence.

A second model of \((\infty, 1)\)-categories is closely related.

E.2.4. DEFINITION (Segal categories). A **Segal precategory** is a bisimplicial set \( X_\bullet \in \mathcal{sSet}^{\Delta^\text{op}} \) whose space of 0-simplices \( X_0 \) is 0-skeletal on the set \( X_{0,0} \) of its vertices. A **Segal category** is a Segal category that is Reedy fibrant and satisfying the Segal condition of Definition E.2.1.

Definition E.2.4 is mildly stronger than the usual definition first introduced by Dwyer, Kan, and Smith [37] and further developed by Hirschowitz and Simpson [53]. The usual convention defines a **Segal category** to be a Segal precategory \( X_\bullet \) so that for each \( n \geq 2 \), the map induced on weighted limits by the inclusion \( \Gamma[n] \hookrightarrow \Delta[n] \) of the spine of the \( n \)-simplex

\[
X_n \cong \lim_{\Delta[n]} X \to X_1 \times_{X_0} \cdots \times_{X_0} X_1 \cong \lim_{\Gamma[n]} \Delta[n]
\]

is a weak homotopy equivalence of simplicial sets—without requiring Reedy fibrancy. We prefer to include Reedy fibrancy in our notion of Segal category so that the Segal categories are precisely the fibrant objects in an appropriate model structure on the category \( \mathcal{P}Cat \) of Segal precategories, which then gives rise to an \( \infty \)-cosmos.
Before we introduce the \(\infty\)-cosmos \textit{Segal}, we explain how to transform a complete Segal space into a Segal category.

E.2.5. \textbf{Lemma.} \textit{There is a functor $\text{disc} : \text{sSet}^{\Delta^{\text{op}} \text{op}} \to \text{sSet}^{\Delta^{\text{op}} \text{op}}$ called discretization defined by the pullback}

\[
\begin{array}{ccc}
\text{disc} (X) & \longrightarrow & X \\
\downarrow & & \downarrow \\
\cosk_0 (X_{0,0}) & \longleftarrow & \cosk_0 (X_0)
\end{array}
\]

that lands in the subcategory of Segal precategories, and indeed is right adjoint to the inclusion $\mathcal{PCat} \hookrightarrow \text{sSet}^{\Delta^{\text{op}}}$. Moreover, the discretization of a Reedy fibrant Segal space is a Segal category.

\textbf{Proof.} Since the “vertex evaluation” map $X \to \cosk_0 (X_0)$ is bijective on the 0th column, the pullback $\text{disc} (X) \to \cosk_0 (X_{0,0})$ must we as well. Hence $\text{disc} (X)_0 \cong X_{0,0}$, which proves that $\text{disc} (X)$ is a Segal precategory. To prove the adjointness, note that for any Segal precategory $Y$ and bisimplicial map $f : Y \to X$, the component $f_0 : Y_0 \to X_0$ factors uniquely through $X_{0,0} \hookrightarrow X_0$ by discreteness of $Y$. This induces the required unique factorization of $f$ through $\text{disc} (X) \hookrightarrow X$.

Finally, any simplicial space that is 0-coskeletal is automatically Reedy fibrant and a Segal space since the maps of Definition E.2.1(i) and (ii) are both isomorphisms. When $X$ is Reedy fibrant, the map $X_n \to \cosk_0 (X_0)_n \cong X_0^n$ is a Kan fibration, so the pullback that defines the simplicial set $\text{disc} (X)_n$ is a homotopy pullback. Applying Lemma C.1.11 to Quillen’s model structure for Kan complexes on simplicial sets, the Segal maps (ii) for $X$ pull back to define analogous weak homotopy equivalences for $\text{disc} (X)$. \square

E.2.6. \textbf{Proposition.} The full subcategory $\text{Segal} \hookrightarrow \mathcal{PCat}$ defines a cartesian closed $\infty$-cosmos in which the functor space $\text{Fun}(A, B)$ is defined to be the underlying quasi-category, formed by the vertices in each internal hom $B^A$. With respect to this $\infty$-cosmos structure:

(i) The underlying quasi-category functor $(-)_0 := \text{row}_0 : \text{Segal} \to \mathcal{QCat}$ is a cosmological biequivalence.

(ii) There is a cosmological biequivalence $\text{disc} : \text{CSS} \to \text{Segal}$ that “discretizes” a complete Segal space into a Segal category.

(iii) There is a second cosmological biequivalence $\text{nerve} : \text{QCat} \to \text{Segal}$, which carries a quasi-category $A$ to the bisimplicial set whose $(m, n)$-simplices are simplicial maps $\Delta [m] \times \Delta [n] \to A$ whose components at each vertex of $\Delta [m]$ are constant.

\textbf{Proof.} By Pellissier and Bergner \cite{87, 11, 13}, the (Reedy fibrant) Segal categories form the fibrant objects in a cartesian closed model structure borne by the category of Segal precategories in which all objects are cofibrant. The cartesian closed structure on $\mathcal{PCat}$ can be defined explicitly, or deduced from the observation that $\mathcal{PCat}$ is a category of presheaves; see Exercise E.2.1.

The adjoint functors of (E.2.3) restrict to an adjunction between simplicial sets and Segal precategories, which Joyal and Tierney again prove define a Quillen equivalence between the model structure for quasi-categories and the model structure for Segal categories \cite{62, 5.6}. Again by inspection, the left adjoint preserves finite products, so Corollary E.1.4 applies to create a cartesian closed $\infty$-cosmos structure on the full subcategory $\text{Segal}$ for which $(-)_0 := \text{row}_0 := \iota^*_0$ is a cosmological biequivalence.

Arguing as in Proposition E.2.2, Proposition E.1.3 applies to create a cartesian closed $\infty$-cosmos structure on the full subcategory $\text{Segal}$, and Lemma A.7.8 and Corollary E.1.2 imply that $(-)_0 := \text{row}_0 := \iota^*_0$ is a cosmological biequivalence.
By a theorem of Bergner, the inclusion ⊣ discretization adjunction of Lemma E.2.5 defines a Quillen equivalence between the model structure for complete Segal spaces and the model structure for Segal categories [13, §6]. To conclude from Corollary E.1.2 that disc: CSS → Segal is a cosmological biequivalence it remains only to show that this functor is simplicially enriched and preserves simplicial cotensors, or equivalently, by Proposition A.4.6, that the adjunction is simplicially enriched. This follows from the fact that this adjunction commutes with the underlying quasi-category adjunctions for CSS and Segal; see Remark E.2.7. In particular, since the inclusion PCat → sSetΔop preserves binary products, for any bisimplicial set C and Segal precategory S, disc(CS) ≅ disc(C)S. A similar argument shows that the simplicial cotensors are preserved. Passing to underlying quasi-categories, this induces the desired simplicially enriched adjunction, which makes disc: CSS → Segal simplicial and hence cosmological.

A second adjunction between simplicial sets and Segal precategories pointing in the opposite direction has left adjoint given by restriction along the diagonal functor Δ: Δop → Δop × Δop and right adjoint, which we call “nerve,” given by right Kan extension along the same followed by discretization. Joyal and Tierney also prove that this adjunction defines a Quillen equivalence with respect to the model structures for complete Segal spaces and quasi-categories [62, 5.7]. As above, to conclude that nerve: QCat → Segal is a cosmological biequivalence it remains only to argue that this adjunction is simplicially enriched. Since the nerve functor is the composite of the right adjoint to the diagonal functor diag: SetΔop×Δop → SetΔop followed by discretization and we have already argued that the latter adjunction is simplicially enriched, it suffices to show that diag ⊣ ran is simplicially enriched.

To that end, consider a bisimplicial set X and a simplicial set A. By definition
\[
(\text{ran}(A)^X)_k := (\text{ran}(A)^X)_{k,0} \\
:= \text{Set}^{\Delta^op \times \Delta^op}(X \times (\Delta[k] \sqcup \Delta[0]), \text{ran}(A)) \\
\cong \text{Set}^{\Delta^op \times \Delta^op}(\text{diag}(X \times (\Delta[k] \sqcup \Delta[0])), A) \\
\cong \text{Set}^{\Delta^op \times \Delta^op}(\text{diag}(X) \times \Delta[k], A) \quad := (A_{\text{diag}}(X))_k,
\]
which is what we wanted to show. □

E.2.7. REMARK. This discretization functor commutes with the underlying quasi-category functors:

\[
\begin{array}{ccc}
\text{CSS} & \xrightarrow{\text{disc}} & \text{Segal} \\
\downarrow^{(-)_0} & & \downarrow^{(-)_0} \\
\text{QCat} & & 
\end{array}
\]

as can most easily be seen by considering the left adjoints to these functors at the level of model categories. However, discretization does not commute with the nerve constructions on the nose, only up to equivalence. For a quasi-category A, nerve(A) is the Segal category with (m, n)-simplices given by the set of simplicial maps Δ[m] × Δ[n] → A whose components at each vertex of Δ[m] are constant. By contrast, disc(nerve(A)) is the Segal category with (m, n)-simplices given by the set of simplicial maps Δ[m] × Δ[n] → A whose components at each vertex of Δ[m] are constant.
E.2.8. **Proposition.** The full subcategory $\text{1-Comp} \hookrightarrow \text{1-sSet}^+$ defines a cartesian closed $\infty$-cosmos in which the functor space $\text{Fun}(A, B)$ is defined to be the underlying quasi-category of the internal hom $B^A$. With respect to this $\infty$-cosmos structure, both the underlying quasi-category functor $(-)_0: \text{1-Comp} \to \text{QCat}$ and the natural marking functor $(-)^\natural: \text{QCat} \to \text{1-Comp}$ are cosmological.

**Proof.** By independent theorems of Lurie [74, §3.1.3-4] and Verity [125, §6.5], the naturally marked quasi-categories, which we call 1-complicial sets, form the fibrant objects in a cartesian closed model structure borne by the category of marked simplicial sets in which all objects are cofibrant. There is an adjunction

$$s\text{Set} \rightleftarrows 1-s\text{Set}^+$$

in which the right adjoint forgets the marking and the left adjoint assigns each simplicial set the minimal marking, which Lurie proves defines a Quillen equivalence between the model structure for quasi-categories and the model structure for 1-complicial sets [74, 3.1.5.1]. By inspection, the left adjoint preserves finite products, so Corollary E.1.4 applies to create a cartesian closed $\infty$-cosmos structure on the full subcategory $1\text{-Comp}$ so that the forgetful functor defines a cosmological biequivalence $(-)_0: 1\text{-Comp} \Rightarrow \text{QCat}$ that coincides with the underlying quasi-category functor. The fact that the model category of 1-complicial sets is enriched over the model structure for quasi-categories via this construction is observed already in [74, 3.1.4.5].

For any quasi-categories $A$ and $B$, observe that there is a natural isomorphism $\text{Fun}(A, B) \cong \text{Fun}(A^\natural, B^\natural)$ between the functor quasi-category in $\text{QCat}$ and the just-defined functor space in $1\text{-Comp}$ between their natural markings; the point is that simplicial maps $A \to B$ preserve isomorphisms and hence the natural markings. Verity shows that the natural marking functor $(-)^\natural: \text{QCat} \to 1\text{-Comp}$ creates the fibrations between fibrant objects [125, 114-118], and hence, since limits in $1\text{-Comp}$ are created in $\text{QCat}$, it follows that the functor $(-)^\natural: \text{QCat} \to 1\text{-Comp}$ is a cosmological biequivalence, and indeed an inverse isomorphism to $(-)_0: 1\text{-Comp} \to \text{QCat}$. □

**Exercises.**

E.2.i. **Exercise.** Joyal and Tierney identify the subcategory $\mathcal{P}\text{Cat} \hookrightarrow \text{Set}^{\Delta^\text{op}\times\Delta^\text{op}}$ with the category of presheaves indexed by the 1-categorical quotient $\Delta_2^\Delta$ of $\Delta \times \Delta$ defined by inverting the maps in the image of the functor $[0] \times \Delta \hookrightarrow \Delta \times \Delta$ [62, 5.4]. Redefine the three adjunctions between $\mathcal{P}\text{Cat}$, $\text{Set}^{\Delta^\text{op}\times\Delta^\text{op}}$, and $\text{Set}^{\Delta^\text{op}}$ appearing in the proof of Proposition E.2.6 from this point of view.

E.2.ii. **Exercise.** As a means of familiarizing oneself with these functors, verify that the cosmological biequivalences nerve: $\text{QCat} \Rightarrow \text{CSS}$ and nerve: $\text{QCat} \Rightarrow \text{Segal}$ each define sections of the respective underlying quasi-category functors.

E.3. **$\infty$-Cosmoi of $(\infty, n)$-Categories**

In this section, we introduce a variety of $\infty$-cosmoi whose objects define models of $(\infty, n)$-categories for $1 < n \leq \infty$. In these cases, the $\infty$-cosmos describes the $(\infty, 2)$-category of $\infty$-categories, $\infty$-functors, and $\infty$-natural transformations, omitting higher-dimensional transformations. In individual cases, internal homs or generalized elements may allow access to higher-dimensional non-invertible morphisms.
Because the combinatorics entailed in precisely specifying a model of \((\infty, n)\)-categories can be rather involved, to save space, we do not define every one of the higher categorical notions discussed here, instead providing external references to where such definitions can be found.

A few of our models of \((\infty, n)\)-categories are defined as presheaves indexed by a 1-category \(\Theta_n\) first introduced by Joyal in an unpublished note \[58\], which we present in an equivalent form due to Berger \[9\].

E.3.1. Definition. For \(0 \leq n \leq \infty\), define a family of 1-categories \(\Theta_n\) inductively as follows.

- \(\Theta_0 := \mathbb{1}\) is the terminal category and \(\Theta_1 := \Delta\) is the category of finite non-empty ordinals and order-preserving maps.
- \(\Theta_n := \Delta \wr \Theta_{n-1}\), where \(\Delta \wr - : \text{Cat} \to \text{Cat}\) is the categorical wreath product construction. Explicitly, for a 1-category \(C\), \(\Delta \wr C\) is the category whose:
  - objects are tuples \([n](c_1,...,c_n)\) where \([n] \in \Delta\) and \(c_i \in C\).
  - morphisms \((\alpha; \vec{f}) : [n](c_1,...,c_n) \to [m](c'_1,...,c'_m)\) are given by a simplicial map \(\alpha : [n] \to [m] \in \Delta\) together with morphisms \(f_{i,j} : c_i \to c'_j \in C\) for all \(0 < i \leq n\) and \(\alpha(i-1) < j \leq \alpha(i)\).

The objects of \(\Theta_n\) define pasting diagrams of \(k\)-cells for \(0 \leq k \leq n\) while the morphisms define projection, composition, and degeneracy maps. The functor \(\Theta_n \hookrightarrow n\text{-Cat}\) that sends a pasting diagram to the free strict \(n\)-category that it generates is full and faithful \[9, 3.7\].

For instance, the morphism in \(\Theta_2\)

\[
[2][(1,1)] \xrightarrow{(\delta^2_i, \delta^1_i, \text{id})} [3][(2,0), (1,1)]
\]

corresponds to the 2-functor between the free 2-categories generated by the pasting diagrams

\[
\begin{array}{ccc}
0 & \xRightarrow{\gamma} & 1 \\
\downarrow & & \downarrow \\
2 & \xRightarrow{\gamma} & 3
\end{array}
\]

that sends 0 to 0, 1 to 1, and 2 to 3, and sends the left 2-cell of the domain to the vertical composite of the leftmost 2-cells of the codomain and the right 2-cell of the domain to the whiskered composite of the rightmost 2-cell of the codomain with the central 1-cell.

E.3.2. Lemma. For any 1-category with a terminal element \(t\), the adjunction below-left induces an adjunction below-right:

\[
\begin{array}{ccc}
\mathbb{1} & \xleftarrow{1} & C \\
\downarrow & & \downarrow \\
\emptyset & \xrightarrow{\Delta t} & \Delta \wr C
\end{array}
\]

\[
\begin{array}{ccc}
\Delta \equiv \Delta \wr \mathbb{1} & \xleftarrow{\Delta t} & \Delta \wr C \\
\downarrow & & \downarrow \\
\Delta t & \xrightarrow{\Delta !} & \Delta \wr C
\end{array}
\]

Proof. The categorical wreath product construction defines a 2-functor \(\Delta \wr - : \text{Cat} \to \text{Cat}\). \(\square\)

Ara introduced a model of \((\infty, n)\)-categories for each \(1 \leq n < \infty\) called \(n\)-quasi-categories as presheaves on \(\Theta_n\) characterized by a particular right lifting property described in \[2, \S5\]. The case of 1-quasi-categories coincides with the usual notion of quasi-categories.

E.3.3. Proposition. For each \(n \geq 1\), the full subcategory \(n\text{-QCat} \hookrightarrow \text{Set}^{\Theta_n^{op}}\) defines a cartesian closed \(\infty\)-cosmos of \(n\)-quasi-categories.
Proof. Ara constructs a cartesian closed model structure on the category $\mathbf{Set}^{\Theta_n^{op}}$ generalizing the Joyal model structure in the case $n = 1$ in which the fibrant objects are exactly the $n$-quasi-categories and in which the cofibrations are the monomorphisms $[2]$; in particular, all objects are cofibrant. Hence, to induce a cartesian closed $\infty$-cosmos structure on the full subcategory $n\text{-QCat}$ it suffices to find a Quillen adjunction between this model structure and the model structure for quasi-categories whose left adjoint $\mathbf{Set}^{\Delta^{op}} \to \mathbf{Set}^{\Theta_n^{op}}$ preserves binary products.

To that end, note that $[0] \in \Theta_{n-1}$ is terminal for all $n > 1$, so Lemma E.3.2 provides an adjunction as below-left and hence an adjunction as below-right

$$\Delta \triangleleft \Theta_n \quad \rightsquigarrow \quad \mathbf{Set}^{\Delta^{op}} \triangleleft \mathbf{Set}^{\Theta_n^{op}}$$

The right adjoint $\Delta t [0]: \Delta \hookrightarrow \Theta_n$ includes $\Delta$ as the subcategory of “pasting diagrams comprised of only 1-cells”; hence, the restriction functor $(\Delta t [0])^*: \mathbf{Set}^{\Theta_n^{op}} \to \mathbf{Set}^{\Delta^{op}}$ forgets higher-dimensional cells. The left adjoint to the inclusion $\mathbf{Cat} \hookrightarrow n\text{-Cat}$, restricts to define the other adjoint $\Delta t! : \Theta_n \to \Delta$. Note that the corresponding restriction functor between categories of presheaves, has its own left adjoint, defined by left Kan extension, and so clearly preserves products.

Indeed, for the same reason, the left adjoint preserves all limits and hence also preserves monomorphisms (which can be characterized as those maps whose kernel pair is given by identities). By a result of Joyal and Tierney [62, 7.15], to prove that an adjunction is Quillen, it suffices to show that the left adjoint preserves cofibrations, as we’ve just done, and the right adjoint preserves fibrations between fibrant objects. By Lemma C.2.6, this means that we need only verify that the left adjoint carries the inner horn inclusions $\{\Lambda^k[n] \hookrightarrow \Delta[n]\}_{n \geq 2, 0 < k < n}$ and the map $1 \hookrightarrow I$ to trivial cofibrations in Ara’s model structure. In fact, by [62, 3.5], it suffices to consider the spine inclusions $\{\Gamma[n] \hookrightarrow \Delta[n]\}_{n \geq 2}$ in place of the inner horn inclusions, which we shall.

To see this, it’s helpful to note, as observed in [2, §6], that the left adjoint commutes with the nerve embeddings of strict 1-categories and strict $n$-categories:

$$\begin{array}{ccc}
\mathbf{Cat} & \xhookrightarrow{\Delta} & n\text{-Cat} \\
\downarrow & & \downarrow \\
\mathbf{Set}^{\Delta^{op}} & \xrightarrow{(\Delta t!)^*} & \mathbf{Set}^{\Theta_n^{op}}
\end{array}$$

In particular, the left adjoint carries the 1-categorical nerve of $1 \hookrightarrow I$ to the strict $n$-categorical nerve of this map and, since the left adjoint also preserves colimits, it carries the inner horn inclusion $\Gamma[n] \hookrightarrow \Delta[n]$ to the corresponding “spine inclusion” for the object $[n](0, ..., 0) \in \Theta_n$. As both types of maps are among Ara’s “localizer of $n$-quasi-categories” of [2, 5.17], they are certainly trivial cofibrations. Hence, the adjunction is Quillen, as claimed, and Corollary E.1.4 applies to create a cartesian closed $\infty$-cosmos structure on $n\text{-QCat}$. □

Another model of $(\infty, n)$-categories, for $0 \leq n < \infty$ is due to Rezk [96]. A $\Theta_n$-space is a simplicial presheaf on $\Theta_n$-satisfying Reedy fibrancy, Segal, and completeness conditions analogous to those of Definition E.2.1. A $\Theta_1$-space is exactly a complete Segal space, while a $\Theta_0$-space is just a Kan complex.
E.3.4. Proposition. For each $n \geq 1$, the full subcategory $\Theta_n\text{-Sp} \hookrightarrow sSet^{\Theta_n^{\text{op}}}$ defines a cartesian closed $\infty$-cosmos of $\Theta_n$-spaces for which the underlying complete Segal space functor $U: \Theta_n\text{-Sp} \to \Theta_1\text{-Sp} \simeq \text{CSS}$ is comological.

Proof. Rezk constructs a cartesian closed model structure on the category $sSet^{\Theta_n^{\text{op}}}$ generalizing his model structure for complete Segal spaces in the case $n = 1$, in which the fibrant objects are exactly the $\Theta_n$-spaces and in which the cofibrations are the monomorphisms [96]; in particular, all objects are cofibrant. Hence, to induce a cartesian closed $\infty$-cosmos structure on the full subcategory $\Theta_n\text{-Sp}$ it suffices to find a Quillen adjunction between this model structure and the model structure for complete Segal spaces whose left adjoint $sSet^{\Delta^{\text{op}}} \to sSet^{\Theta_n^{\text{op}}}$ preserves binary products. We then apply Corollary E.1.4 to the composite of this adjunction with the adjunction (E.2.3).

As in the proof of Proposition E.3.3, we obtain the desired adjunction from Lemma E.3.2 applied to the terminal object $[0] \in \Theta_{n-1}$.

\[
\begin{array}{ccc}
\Delta & \xleftarrow{\Delta[0]} & \Theta_n \\
& \searrow & \\
\Delta[1] & \downarrow & sSet^{\Delta^{\text{op}}} \\
& \nearrow & \\
& (\Delta[1])^* & sSet^{\Theta_n^{\text{op}}}
\end{array}
\] (E.3.5)

The left adjoint has a further left adjoint given by left Kan extension, and so preserves products.

It remains only to argue that this adjunction is Quillen. The model structure for $\Theta_n$-spaces, and by specialization, also the model structure for complete Segal spaces, are defined as left Bousfield localizations of the injective (or, equivalently, Reedy) model structures on simplicial presheaves. In the injective model structures, the cofibrations and trivial cofibrations are defined objectwise in $sSet$, so the left adjoint restriction functor is manifestly left Quillen with respect to these model structures. Consequently, the adjunction is Quillen for the localized model structures, if and only if the right adjoint, which Rezk refers to as the “underlying simplicial space” functor, preserves fibrant objects, because in that case the left adjoint will preserve the new trivial fibrations, which are defined in terms of these. A functor $X \in sSet^{\Theta_n^{\text{op}}}$ is fibrant if and only if it satisfies Reedy, Segal, and completeness conditions. Since the adjunction (E.3.5) is Quillen for the injective/Reedy model structure, the Reedy fibrancy condition is preserved, and Rezk proves that the Segal condition is preserved as well [96, 7.2]. By definition, the completeness condition for $\Theta_n$-spaces is created from the completeness condition for underlying simplicial spaces [96, §7], so this is preserved as well. Hence, the right adjoint (E.3.5) restricts to a functor $U: \Theta_n\text{-Sp} \to \text{CSS}$, which we call the underlying complete Segal space functor.

Corollary E.1.4 applies to create a cartesian closed $\infty$-cosmos structure on $\Theta_n\text{-Sp}$. By Lemma A.7.8, the adjunction (E.3.5) is enriched over bisimplicial sets, and so Proposition E.1.3 can be used to prove that the underlying complete Segal space functor is cosmological.

There is another model for $(\infty, n)$-categories that generalizes the complete Segal space model for $(\infty, 1)$-categories, which makes use of the notion of a Rezk object valued in a model category:

E.3.6. Definition. Let $\mathcal{M}$ be a model category.

(i) A simplicial object $X_\bullet \in \mathcal{M}^{\Delta^{\text{op}}}$ is Reedy fibrant just when the induced map on weighted limits

\[
X_m \cong \lim_{\Delta[m]} X \to \lim_{\partial\Delta[m]} X \coloneqq M_m X
\]

is a fibration for all $m \geq 0$. 

597
(ii) A Reedy fibrant simplicial object $X_\bullet$ is a Segal object just when the induced map on weighted limits
\[
X_n \cong \lim_{\Delta[n]} X \to \lim_{\mathcal{M}[n]} X
\]
is a trivial fibration for all $n \geq 2$ and $0 < k < n$.

(iii) A Segal object $X_\bullet$ is a Rezk object, just when the induced map on weighted limits
\[
\lim_{\mathcal{I}} X \to \lim_{\Delta[0]} X \cong X_0
\]
is a trivial fibration.

A map $p : X_\bullet \to Y_\bullet \in \mathcal{M}^{\Delta^\text{op}}$ is a Rezk isofibration if the relative analogues of the maps appearing in (i), (ii), and (iii) formed by the Leibniz weighted limit of $p$ with the appropriate maps of weights, are respectively fibrations, trivial fibrations, and a trivial fibration.

Our formulation of Definition E.2.1, which departs slightly from Rezk's framing of his conditions, is intended to make it clear that the complete Segal spaces are precisely the Rezk objects valued in Quillen's model structure for Kan complexes.

E.3.7. PROPOSITION. Suppose $\mathcal{M}$ is a Cisinski model category.⁶ Then the full subcategory $\mathcal{R}\text{ezk}_\mathcal{M} \hookrightarrow \mathcal{M}^{\Delta^\text{op}}$ of Rezk objects defines an $\infty$-cosmos.

PROOF. We prove this result directly from Proposition E.1.1 by proving that a left Bousfield localization of the Reedy model structure on $\mathcal{M}^{\Delta^\text{op}}$ defines a Cisinski model structure that is enriched over the model structure for quasi-categories in which the fibrant objects are exactly the Rezk objects.

To begin, observe that the category $\mathcal{M}^{\Delta^\text{op}}$ is enriched, tensored, and cotensored over simplicial sets
\[
(\otimes, [\cdot, \cdot], \text{Fun}) : \mathcal{S}et \times \mathcal{M}^{\Delta^\text{op}} \to \mathcal{M}^{\Delta^\text{op}}
\]
with homs suggestively denoted by “Fun,” in such a way that the Leibniz tensors of monomorphisms of simplicial sets with (trivial) Reedy cofibrations are (trivial) Reedy cofibrations [35, 4.4]. We will apply Jeff Smith's theorem [6] to prove that $\mathcal{M}^{\Delta^\text{op}}$ admits a model structure in which
- the cofibrations are the Reedy/injective cofibrations, these being the monomorphisms,
- the fibrant objects are the Rezk objects,
- the fibrations between fibrant objects are the Rezk isofibrations, and
- weak equivalences are the Rezk weak equivalences, though maps $U \to V$ that induce equivalences
  of quasi-categories $\text{Fun}(V, X) \to \text{Fun}(U, X)$ for all Rezk objects $X$.

Note that by adjunction, a map $p : X \to Y \in \mathcal{M}^{\Delta^\text{op}}$ is a Rezk isofibration if and only if for all
monomorphisms $m : A \to B \in \mathcal{M}$, the induced map
\[
\mathcal{M}(B, X) \xrightarrow{\mathcal{M}(m, p)} \mathcal{M}(A, X) \boxtimes \mathcal{M}(A, Y) \to \mathcal{M}(B, Y)
\]
of simplicial sets is an isofibration of quasi-categories; see Exercise C.2.v. By Corollary D.3.12 and
Proposition D.5.1, this is the case if and only if this map has the right lifting property with respect to maps in the set
\[
\mathcal{I} \times \mathcal{J}, \quad \text{where } \mathcal{I} := \{ \partial \Delta[n] \hookrightarrow \Delta[n] \}_{n \geq 0} \quad \text{and} \quad \mathcal{J} := \{ \Lambda^k[n] \hookrightarrow \Delta[n] \}_{n \geq 2, 0 < k < n} \cup \{ 1 \hookrightarrow 1 \}.
\]

A Cisinski model structure is a combinatorial model structure on a Grothendieck topos in which the cofibrations are exactly the monomorphisms. It follows that the Reedy model structure on $\mathcal{M}^{\Delta^\text{op}}$ coincides with the injective model structure, and in particular that all objects are cofibrant [28, 15].
By adjunction again, and Proposition C.2.9(i), $p$ is a Rezk isofibration if and only if it has the right lifting property with respect to the sets of maps $(i \times j)^*m \cong j^*(i^*m)$ for all $i \in I$, $j \in J$, and $m$ among the generating cofibrations in $M$, where $*$ denotes the pointwise tensor: $sSet \times M \to M^{\Delta^\text{op}}$ and $\otimes: sSet \times M^{\Delta^\text{op}} \to M^{\Delta^\text{op}}$ denotes the simplicial tensor. Since by Proposition C.5.8 the Reedy cofibrations in $M^{\Delta^\text{op}}$ are generated by the set of maps $i^*m$ for $i \in I$ and as $m$ ranges over the generating cofibrations in $M$, we conclude, again by adjunction, that $p$ is a Rezk isofibration between Rezk objects if and only if

$\text{Fun}(V, X) \xrightarrow{\text{Fun}(c,p)} \text{Fun}(U, X) \times_{\text{Fun}(U, Y)} \text{Fun}(V, Y)$

is an isofibration of quasi-categories for all monomorphisms $c: U \to V$ in $M^{\Delta^\text{op}}$.

Now it’s easy to verify the conditions of Jeff Smith’s theorem. The Rezk weak equivalences are accessible and satisfy the 2-of-3 property. We argue that the Rezk weak equivalences contain all Reedy weak equivalences and hence the Reedy trivial fibrations, characterized by the right lifting property against the monomorphisms. Transposing the observations already made in [35, 4.4] about the Reedy model structure on $M^{\Delta^\text{op}}$, we see that for any Reedy trivial cofibration $w: U \to V$ and Rezk object $X$, $w^*: \text{Fun}(V, X) \to \text{Fun}(U, X)$ is an equivalence of quasi-categories. By Ken Brown’s lemma C.1.10, the same is true when $w$ is a mere Reedy weak equivalence. Note that a map $w: U \to V$ is both a Rezk weak equivalence and a cofibration just when $w^*: \text{Fun}(V, X) \to \text{Fun}(U, X)$ is a trivial fibration between quasi-categories. This characterization proves that the class of Rezk weak equivalences and cofibrations is stable under pushout and transfinite composition. Smith’s theorem now implies that the model structure for Rezk objects exists.

To see that the model structure for Rezk objects is enriched over the model structure for quasi-categories, we must verify the three conditions for

$(\otimes, [\cdot, \cdot], \text{Fun}): sSet \times M^{\Delta^\text{op}} \to M^{\Delta^\text{op}}$

to define a Quillen two-variable adjunction; see Definition C.3.8. The fact that Leibniz tensors of cofibrations are cofibrations was verified already for the Reedy model structure on $M^{\Delta^\text{op}}$ and the localized model structure for Rezk objects has the same cofibrations. To verify the remaining 2/3rds of this axiom, we appeal to a result of Dugger [35, 3.2], which tells us that in the presence of the first 1/3rd, to verify that Leibniz tensors of monomorphisms of simplicial sets with trivial cofibrations are trivial cofibrations, it suffices to show that the simplicial cotensor $(-)^K: M^{\Delta^\text{op}} \to M^{\Delta^\text{op}}$ preserves fibrations between fibrant objects. For left Bousfield localizations, Rezk fibrations between Rezk objects coincide with Reedy fibrations between Rezk objects [52, 3.3.16]. It’s easy to verify directly that $(-)^K$ preserves Rezk objects, and the preservation of Reedy fibrations is one of the facts we knew already.

For the final 1/3 of the Quillen two-variable adjunction, we use the second part of Dugger’s [35, 3.2], which tells us that in the presence of the first 2/3rds, we need only verify that for all Rezk objects $Z$ and trivial cofibrations of simplicial sets $j: J \to K$, the map $Z^j: Z^K \to Z^J$ is a Rezk weak equivalence (assuming $M^{\Delta^\text{op}}$ is left proper, which is the case here since all objects are cofibrant). In fact, we can show that this map is a trivial fibration, by checking the right lifting property against the monomorphisms $c: U \to V \in M^{\Delta^\text{op}}$. Transposing, we see that $c$ lifts against $Z^j$ if and only if $j$ lifts against $c^*: \text{Fun}(V, Z) \to \text{Fun}(U, Z)$. But we verified three paragraphs above that $c^*$ is an isofibration between quasi-categories, so the desired lifting property holds. □
Barwick’s $n$-fold complete Segal space model of $(\infty, n)$-categories is formed by iterating the Rezk objects construction $n$ times [4]; note that the model structure for Rezk objects on $\mathcal{M}^{\Delta^\text{op}}$ remains a Cisinski model structure, so this construction can be iterated. Specialization Proposition E.3.7, we conclude that for all $n \geq 1$, there exist $\infty$-cosmoi $\mathcal{CSS}_n$ of $n$-fold complete Segal spaces.

E.3.8. REMARK. If $\mathcal{M}$ is a left proper combinatorial model category, the proof just given constructs a model structure on $\mathcal{M}^{\Delta^\text{op}}$ whose fibrant objects are the Rezk objects that is enriched as a model category over the model structure for quasi-categories. The only hitch is that without the Cisinski condition, it’s possible that not all fibrant objects are cofibrant. Nonetheless, this generalization can be understood as defining an $\infty$-cosmos in a weaker sense developed in [105, §2].

Verity constructs a general family of cartesian model structures on the category of marked simplicial sets whose fibrant objects are complicial sets of various flavors and whose fibrations are the corresponding notions of complicial fibration [125, §9.3]. A restriction of one of these model structures to the case of 1-trivial marked simplicial sets, with all simplices above dimension 1 marked, underlies the $\infty$-cosmos of Proposition E.2.8. Here, we consider model structures whose fibrant objects model $(\infty, n)$-categories for $0 \leq n \leq \infty$, in which case we write complicial set to mean $\infty$-complicial set. The definitions are arranged so that a 0-complicial set is a (maximally marked) Kan complex, a 1-complicial set is a (naturally marked) quasi-category, and a $k$-complicial set is an $n$-complicial set whenever $m < n$.

E.3.9. PROPOSITION. For each $0 \leq n \leq \infty$, the full subcategory in the category of marked simplicial sets spanned by the complicial sets defines a cartesian closed $\infty$-cosmos $\mathcal{CSS}_n$. Moreover, whenever $m < n$, the functor $\text{core} : \mathcal{CSS}_n \to \mathcal{CSS}_m$ that discards all simplices in dimension $k > m$ that are not marked is cosmological.

PROOF. For a suitable class of monomorphisms $\mathcal{J}$, Verity defines a cartesian closed model structure on the category of marked simplicial sets whose fibrant objects and fibrations between them are the $\mathcal{J}$-complicial sets and $\mathcal{J}$-complicial fibrations, characterized by a right lifting property against $\mathcal{J}$ [125, §9.3]. The cofibrations are the monomorphisms so in particular all objects are cofibrant. In more detail, for the $m$-complicial sets, the class of monomorphisms is defined to be

$$\mathcal{J}_m \coloneqq \left\{ \Lambda^k[m] \hookrightarrow \Lambda^k[m] \right\}_{m \geq 1, k \in \mathbb{N}[m]} \cup \left\{ \Lambda^k[m] \hookrightarrow e \Lambda^k[m] \right\}_{m \geq 2, k \in \mathbb{N}[m]} \cup \left\{ \Delta[r] \hookrightarrow e \Delta[r] \right\}_{r > m} \cup \left\{ \Delta[j] \ast \Delta[3]_{\text{eq}} \ast \Delta[k] \hookrightarrow \Delta[j] \ast \Delta[3] \ast \Delta[k] \right\}_{j, k \geq -1}$$

See [100] for an explanation of this notation. The first set of maps are referred to as the complicial horn extensions while the second set define the complicial thinness extensions. The third set imposes the condition that all simplices in dimension greater than $n$ are marked, while the final condition is saturation, which in the presence of the other conditions, implies that all equivalences are marked. To apply Verity’s theorem, the sets $\mathcal{J}_m$ must satisfy some technical conditions spelled out in [125, 91-92], which have been verified in this case by Viktoria Ozornova and Martina Rovelli [110, 1.26].

By construction, the $n$-complicial sets live in the subcategory $n+sSet^+$ of $n$-trivial marked simplicial sets (with all simplices in dimension greater than $n$ marked), and we may restrict the cartesian closed model structures to these subcategories.

The $\infty$-cosmoi $0\text{-Comp}$ and $1\text{-Comp}$ are isomorphic to the $\infty$-cosmoi $\mathcal{Kam}$ and $\mathcal{QCat}$ respectively, so for now we consider $2 \leq n \leq \infty$. To define the $\infty$-cosmos $n\text{-Comp}$, we apply Proposition E.1.3 to convert these self enrichments into an enrichment over quasi-categories via a string of Quillen
adjunctions whose left adjoints preserve binary products:

\[
\begin{array}{cccccc}
\downarrow_{\text{Set}} & \downarrow & 1\text{-Set}^+ & \downarrow & 2\text{-Set}^+ & \downarrow & \cdots & \downarrow & (n-1)\text{-Set}^+ & \downarrow & n\text{-Set}^+ & \cdots \\
\downarrow_{\text{core}_1} & & & & & & & & & & & \\
\downarrow & & & & & & & & & & & \\
\text{Set} & \xleftarrow{\text{(n)}} & 1\text{-Set}^+ & \xleftarrow{\text{core}_1} & 2\text{-Set}^+ & \xleftarrow{\text{core}_1} & \cdots & \xleftarrow{\text{core}_1} & (n-1)\text{-Set}^+ & \xleftarrow{\text{core}_1} & n\text{-Set}^+ & \cdots \\
\end{array}
\]

In the limiting case, we also consider adjunctions

\[
\begin{array}{cccc}
\downarrow_{\text{Set}} & \downarrow & n\text{-Set}^+ & \downarrow \\
\downarrow_{\text{core}_n} & & & \\
n\text{-Set}^+ & \xleftarrow{\text{core}_n} & Strat \\
\end{array}
\]

where \(\text{core}_n X \hookrightarrow X\) is the simplicial subset containing only those simplices in dimension greater than \(n\) that are marked. By adjunction it is easy to verify that these functors carry \((n+1)\)-complicial sets to \(n\)-complicial sets. Since the left adjoints preserve monomorphisms and products, this is enough to verify that the adjunctions are Quillen. Corollary E.1.4 now induces the desired \(\infty\)-cosmoi and Proposition E.1.3 supplies the cosmological core functors.

Building on past work of Hirschowitz-Simpson [53] and Pellissier [87], Simpson iterates the construction of the model structure for Segal categories [112, §19.2-4]. When the base model category is taken to be Quillen’s model structure for Kan complexes, the \(n\)-th iteration defines the notion of Segal \(n\)-categories, though Simpson also considers more general model categorical bases. Under suitable hypotheses, satisfied in the case of Segal \(n\)-categories, the model structure so produced is cartesian closed and has all objects cofibrant, which strongly suggests that there exists an \(\infty\)-cosmos spanned by its fibrant objects: the Reedy fibrant Segal \(n\)-categories. We leave the confirmation of this as an exercise for the interested reader.

**Exercises.**

E.3.i. **Exercise.** Given an explicit formulation of the “relative analogue” of the conditions (i), (ii), and (iii) used in Definition E.3.6 to define the notion of Rezk isofibration.

E.3.ii. **Exercise.** Investigate potential \(\infty\)-cosmos structures on the Segal \(n\)-categories of Hirschowitz and Simpson [53].

E.3.iii. **Exercise.** Search for cosmological biequivalences between the \(\infty\)-cosmoi constructed in this section (and please share your discoveries with the authors).
The analytic theory of quasi-categories

The aim in this section is to prove that the synthetic theory of quasi-categories is compatible with the analytic theory pioneered by André Joyal, Jacob Lurie, and many others.

F.1. Initial and terminal elements

In this section, we complete the argument sketched in Digression 4.3.14 and prove that the synthetic definition of a terminal element in a quasi-category coincides with the analytic definition first introduced by Joyal [59, 4.1]. In the following result, we prove the equivalence between three synthetic definitions of a terminal element—(i), which appeared first in Definition 2.2.1, (ii), which is essentially contained in Lemma 2.2.2, and (iii), which appeared as Proposition 4.3.13—and two analytic definitions of a terminal element (v) and (vi), which Joyal proves are equivalent [59, 4.2].

F.1.1. Proposition. For a quasi-category $A$ and element $t: 1 \to A$ the following are equivalent:

(i) The element $t$ defines a right adjoint to the unique functor:

(ii) There exists a natural transformation

so that the component $\eta t$ is an isomorphism.

(iii) The domain-projection functor

defines a trivial fibration.

(iv) For any element $a: 1 \to A$, the internal mapping space $\text{Hom}_A(a, t)$ is contractible.

(v) The projection functor

whose domain is the slice of $A$ over $t$ is a trivial fibration.
(vi) Any sphere in \( A \) whose final vertex is \( t \) admits a filler:

\[
\begin{array}{ccc}
1 & \xrightarrow{\text{filler}} & \partial \Delta[n] \\
\text{[n]} & & \downarrow \\
\Delta[n] & \xrightarrow{t} & A
\end{array}
\]

When these conditions hold, \( t \) defines a terminal element of \( A \).

**Proof.** Unpacking (i), all that is required to define an adjunction \( ! \dashv t \) is to define a unit natural transformation \( \eta : \text{id}_A \Rightarrow t! \) so that the component \( \eta t = \text{id}_t \) is an identity; see Lemma 2.2.2. But it suffices, as claimed by (ii), to require only that \( \eta t \) is an isomorphism. The proof is a specialization of Lemma B.4.2. The vertical composite \( (\eta t) \cdot (\eta t) \) is computed by the pasting diagram:

\[
\begin{array}{ccc}
1 & \xrightarrow{t} & A \\
\downarrow & & \downarrow \\
1 & \xrightarrow{!} & A
\end{array}
\]

By middle-four interchange, we can evaluating this composite by first whiskering the left-hand \( ! \) with \( t \), which yields \( !\eta = \text{id}_! \) since the quasi-category \( 1 \) is 2-terminal.\(^1\) Hence \( (\eta t) \cdot (\eta t) = (\eta t) \), so \( \eta t \) is an idempotent isomorphism, and hence, by cancelation, an identity. This proves the equivalence of (i) and (ii).

Proposition 4.3.13 establishes the equivalences of (i) and (iii) in any \( \infty \)-cosmos. By Corollary 12.2.13 and Corollary 5.6.17, the domain projection functor is a trivial fibration if and only if its fibers \( \text{Hom}_A(a, t) \) are contractible, proving the equivalence of (iii) and (iv).

By Proposition D.6.4, for any vertex \( t \) in a quasi-category, we have an equivalence

\[
\text{Hom}_A(A, t) \xrightarrow{\sim} A_{/t}
\]

between the domain-projection isofibration and the canonical projection from the slice construction of Proposition 4.2.5. Consequently, by the two-of-three property, one isofibration is an equivalence if and only if the other is, proving the equivalence of (iii) and (v).

By Definition 1.1.24, the projection \( A_{/t} \to A \) is a trivial fibration if and only if the following right lifting property holds for all \( n \geq 0 \)

\[
\begin{array}{ccc}
\partial \Delta[n] & \xrightarrow{u} & A_{/t} \\
\downarrow & \searrow & \downarrow \\
\Delta[n] & \xrightarrow{v} & A
\end{array}
\]

Via the adjunction

\[
s\text{Set} \cong \Delta[0] \downarrow s\text{Set}
\]

\(^1\)See the discussion in the paragraph preceding Proposition 1.4.5.
the sphere \( u: \partial \Delta[n] \to A \) transposes into a map \( \Lambda^{n+1}[n+1] \to A \) with final vertex \( A \), with the simplex \( v: \Delta[n] \to A \) providing a filler for the open face of the horn. Thus, together the maps \( u \) and \( v \) transpose to define a sphere \( \partial \Delta[n+1] \to A \) with final vertex \( t \). The desired lift \( w: \Delta[n] \to A \) exists just when this transposed sphere admits a filler. In this way, we see that the right lifting properties

\[
\begin{array}{c}\partial \Delta[n] \to A \downarrow \downarrow \downarrow \downarrow \downarrow \\
\Delta[n] \to A
\end{array}
\begin{array}{c}1 \to \partial \Delta[n] \to A \downarrow \downarrow \downarrow \downarrow \downarrow \\
\Delta[n] \to A
\end{array}
\forall n \geq 1
\]

are transposes, proving the equivalence of (v) and (vi).

There is a relative extension of Joyal’s characterization (vi), which is involved with the construction of a homotopy coherent adjunction.

F.1.2. Lemma. Suppose \( E \) and \( B \) are quasi-categories which possess a terminal element and \( p: E \to B \) is an isofibration which preserves them: if \( t \) is terminal in \( E \) then \( pt \) is terminal in \( B \). Then any lifting problem of the following form has a solution

\[
\begin{array}{c}1 \to \partial \Delta[n] \to E \downarrow \downarrow \downarrow \downarrow \downarrow \\
\Delta[n] \to B
\end{array}
\]

Proof. Using the universal property of the terminal object \( t \) in \( E \) and Proposition F.1.1(vi), we we may extend the sphere \( u \) to a map \( w: \Delta[n] \to E \). This defines two maps \( pw, v: \Delta[n] \to B \) with a common boundary \( pu: \partial \Delta[n] \to B \), which we may use to define a sphere \( h: \partial \Delta[n+1] \to B \) with \( h\delta^{n+1} = pw \) and \( h\delta^n = v \) by starting with the degenerate simplex \( pw\sigma^n: \Delta[n+1] \to B \), restricting to its boundary, and then replacing the \( n \)th face in this sphere with \( v: \Delta[n] \to B \). By construction, \( h \) maps the object \( [n+1] \) to the object \( pt \) which is terminal in \( B \), so it follows that we may fill this sphere to define a simplex \( k: \Delta[n+1] \to B \).

We may also construct a map \( g: \Lambda^n[n+1] \to E \) by restriction from the degenerate simplex \( w\sigma^n: \Delta[n+1] \to E \), which then defines a factorization of the commutative square of the statement:

\[
\begin{array}{c}\partial \Delta[n] \to E \downarrow \downarrow \downarrow \downarrow \downarrow \\
\Delta[n] \to B
\end{array}
\begin{array}{c}\partial \Delta[n] \to \Delta^n[n+1] \to E \downarrow \downarrow \downarrow \downarrow \downarrow \\
\Delta[n] \to \Delta[n+1] \to B
\end{array}
\]

Since the central vertical of this commutative rectangle is an inner horn inclusion and its right hand vertical is an isofibration of quasi-categories, it follows that the lifting problem on the right has a solution \( \ell: \Delta[n+1] \to E \) as marked, and now it is clear that the map \( \ell\delta^n: \Delta[n] \to E \) provides a solution to the original lifting problem.

□
Exercises.

F.1.i. EXERCISE. Prove that if $A$ and $B$ are quasi-categories which possess a terminal element and $f: A \to B$ is a functor which preserves terminal elements, then given any lifting problem as below-left in which $t$ is terminal in $A$

\[
\begin{array}{ccc}
1 & \xrightarrow{[n]} & \partial \Delta[n] & \xrightarrow{\partial} & A \\
\downarrow & & \downarrow f & & \downarrow f \\
\Delta[n] & \xrightarrow{\sim} & B
\end{array}
\]

there exists a lift as above-right so that the upper-left triangle commutes up to natural isomorphism and the bottom-right triangle commutes on the nose.

F.2. Limits and colimits

In this section, we expand Proposition 4.3.2 to prove that the synthetic definition of a limit of a diagram indexed by a simplicial set and taking values in a quasi-category coincides with the analytic definition first introduced by Joyal [59, 4.5]. In the following result, we prove the equivalence between four synthetic definitions of a limit cone—(i), the original Definition 2.3.7, (ii), appearing in Proposition 4.3.4, and (iv), from Proposition 4.3.2—and one analytic one (v), which is Joyal’s. In this case, by the results just cited and Proposition F.1.1, there is nothing left to do but state the result and provide references for its components.

F.2.1. PROPOSITION. Consider a diagram $d: J \to A$, where $J$ is a simplicial set and $A$ is a quasi-category. The following are equivalent

(i) There exists an absolute right lifting diagram

\[
\begin{array}{ccc}
1 & \xrightarrow{d} & A^l \\
\downarrow & & \downarrow \triangleleft \lambda \\
& & A
\end{array}
\]

(ii) There exists an absolute right lifting diagram

\[
\begin{array}{ccc}
1 & \xrightarrow{d} & A^l \\
\downarrow & & \downarrow \triangleleft \lambda \triangleleft \res \\
& & A^l
\end{array}
\]

(iii) There exists a pointwise right extension diagram

\[
\begin{array}{ccc}
J & \xrightarrow{d} & A \\
\downarrow & & \downarrow \triangleleft \lambda \\
1 & \xrightarrow{d} & A
\end{array}
\]
(iv) The quasi-category of cones \( \text{Hom}_{A/I}(\Delta, d) \) admits a terminal element \( \lambdasym \), representing a cone

\[
\begin{array}{ccc}
1 & \downarrow \lambdasym & A \\
\text{Hom}_{A/I}(\Delta, d) & \phi & A/I \\
\downarrow p_0 & & \downarrow \Delta \\
1 & \phi & A/I \\
d & \Delta & \Delta \\
\end{array}
\]

(v) The quasi-category \( A_{id} \) admits a terminal element \( \lambdasym : 1 \to A_{id} \), transposing to define an extension of \( d \) to a diagram

\[
\begin{array}{ccc}
J & \lambdasym & A \\
\downarrow J^\text{nd} & & \downarrow \Delta \\
A/I & d & A/I \\
\end{array}
\]

When these conditions hold, the data variously labeled (\( \ell, \lambda \)) or \( \lambdasym \) defines the limit cone over \( d \).

PROOF. The equivalence of (i) and (ii) is proven in Proposition 4.3.4 for any \( \infty \)-category \( A \) and simplicial set \( J \); the simplicial set \( J^\text{nd} \) is the join from Definition 4.2.4. The equivalence of (i) and (iii) is proven in Proposition 4.3.4 for any cartesian closed \( \infty \)-cosmos. Proposition 4.3.2 proves the equivalence between (i) and (iv) for any diagram valued in any \( \infty \)-cosmos.

Finally, the equivalence between (iv) and (v) is a consequence of the equivalence of quasi-categories \( \text{Hom}_{A/I}(\Delta, d) \cong A_{id} \) over \( A \) of Proposition D.6.5, which provides two models for the quasi-category of cones over \( d \). The final ingredient Lemma 2.2.7, which that if one of these quasi-categories has a terminal element, they both do, as terminal elements are preserved by the equivalence. \( \square \)

F.3. Right adjoint right inverse adjunctions

To our knowledge, right adjoint right inverse adjunctions between quasi-categories have not been given much attention. Nonetheless, we pause to establish a useful analytic characterization of such adjunctions, which will help us compare various other synthetic and analytic definitions.

F.3.1. LEMMA. An isofibration \( f : B \to A \) of quasi-categories admits a right adjoint right inverse if and only if for every element \( a : 1 \to A \), there exists an element \( u^a : 1 \to B \) with \( fu^a = a \) that has the property that any lifting problem with \( n \geq 1 \)

\[
\begin{array}{ccc}
1 & \xrightarrow{u^a} & \partial \Delta[n] \\
\downarrow [n] & & \downarrow f \\
\Delta[n] & \xrightarrow{f} & A \\
\end{array}
\]

has a solution.
PROOF. If \( u \) is the right adjoint right inverse, then \( \epsilon: fu = \text{id}_A \) is the identity, and the induced fibered equivalence \( ^*\epsilon \circ f(-)^*: \text{Hom}^B(B, u) \Rightarrow \text{Hom}^A(f, A) \) of Proposition 4.1.1 is represented by the map induced by \( f \) between the comma \( \infty \)-categories defined in Proposition 3.4.5.

By that result—or alternatively, by Proposition C.1.12, on which its proof relies—we see that the induced map between comma \( \infty \)-categories is also an isofibration. Combining these facts, we see that \( ^*\epsilon \circ f(-)^*: \text{Hom}^B_B(B, u) \Rightarrow \text{Hom}^A_A(f, A) \) is a trivial fibration over \( A \times B \). This trivial fibration pulls back over any vertex \( a: 1 \rightarrow A \) to define a trivial fibration \( \text{Hom}^B_B(B, ua) \Rightarrow \text{Hom}^A_A(f, a) \) over \( B \). By Corollary D.6.6, the domain and codomain are equivalent to Joyal’s slices, so the isofibration \( f: B_{/ua} \Rightarrow f_{/a} \) induced by \( f \) is also a trivial fibration between quasi-categories. The defining lifting property of Definition 1.1.24

\[
\partial \Delta[n-1] \xrightarrow{\epsilon \Delta[n-1]} B_{/ua} \xrightarrow{\eta \Delta[n-1]} f_{/a}
\]

for \( n \geq 1 \) transposes to the lifting property of (F.3.2).

Conversely, the lifting property (F.3.2) can be used to inductively define a section \( u: A \rightarrow B \) of \( f \) extending the choices of elements \( ua: 1 \rightarrow B \) lifting each \( a: 1 \rightarrow A \). The inclusion \( \text{sk}_0 A \hookrightarrow A \) can be expressed as a countable composite of pushouts of coproducts of maps \( \partial \Delta[n] \hookrightarrow \Delta[n] \) with \( n \geq 1 \), and each intermediate lifting problem required to define a lift

\[
\xymatrix{ 1 \ar[r]^a & \text{sk}_0 A \ar[r]^u & B \ar[r]^f & A }
\]

will have the form of (F.3.2). To show that \( u \) is a right adjoint right inverse to \( f \), it suffices, by Lemma B.4.2 to define a 2-cell \( \eta: \text{id}_B \Rightarrow uf \) that whiskers with \( u \) and with \( f \) to isomorphisms. We construct a representative for \( \eta \) by solving the lifting problem

\[
\xymatrix{ B \sqcup B \ar[r]^{\text{id}_B \sqcup uf} & B \ar[d]^{\eta} & B \ar[r]^{f} & A }
\]

\[
\xymatrix{ B \times \Delta[1] \ar[r]_{\pi} & B \ar[r]^{f} & A }
\]

By construction \( f\eta = \text{id}_f \) is certainly invertible.
To show that $\eta u$ is an isomorphism it suffices, by Corollary D.4.18, to check that each of its components $\eta u(a) : u a \to u f u a = u a$ are isomorphisms in $A$. Inverse isomorphisms can be found by elementary applications of the lifting property (F.3.2), whose details we leave to the reader.  

F.4. Cartesian and cocartesian fibrations

The aim in this section is to establish the equivalence between synthetic and analytic characterizations of when an isofibration $p : E \to B$ between quasi-categories defines a cartesian or cocartesian fibration. The following result compares the three synthetic definitions proven equivalent in Theorem 5.2.10 with two analytic definitions due to Lurie [74, §2.4.1]. After we give its proof we comment on a few non-obvious aspects of the comparison.

F.4.1. Proposition. For an isofibration $p : E \to B$ between quasi-categories, the following are equivalent and define what it means for $p$ to be a cartesian fibration:

(i) Every natural transformation $\beta : b \Rightarrow pe$ as below-left admits a lift $\chi : e' \Rightarrow e$ as below-right:

\[
\begin{array}{c}
\xymatrix{ X \ar[r]^e & E \\
 b \ar[u]^\beta \ar[r]_{pe} & B \\
}
\end{array}
\quad = \quad
\begin{array}{c}
\xymatrix{ X \ar[r]^e & E \ar[d]^p \\
 e' \ar[u]^\chi & B \\
}
\end{array}
\]

with the property that:

- **induction**: Given any functor $x : Y \to X$ and natural transformations $Y \xleftarrow{\tau} E$ and $Y \xrightarrow{\gamma} B$ so that $p \tau = p \chi x \cdot \gamma$, there exists a lift $Y \xleftarrow{\gamma'} E$ of $\gamma$ so that $\tau = \chi x \cdot \gamma'$.

- **conservativity**: Any fibered endomorphism of a restriction of $\chi$ is invertible: if $Y \xrightarrow{\zeta} E$ is any natural transformation so that $\chi x \cdot \zeta = \chi x$ and $p \zeta = id_{pe'}$ then $\zeta$ is invertible.

(ii) The functor $\text{id}_p \gamma : E \to \text{Hom}_B(B, p)$ admits a right adjoint over $B$.

(iii) The functor $k := \{\delta^0, p\} : E^2 \to \text{Hom}_B(B, p)$ admits a right adjoint right inverse.

(iv) Any 1-simplex $\beta : b \to pe$ in $B$ admits a lift $\chi : e' \to e$ in $E$ so that any lifting problem for $n \geq 1$

\[
\begin{array}{c}
\xymatrix{ \Delta[1] \ar[r]_{\Delta[1]} \ar[d]_{n \times \text{id}} & \partial \Delta[n] \times \Delta[1] \ar[r]_{\Delta[n] \times \{1\}} & \Delta[n] \times \{1\} \ar[r] & E \\
 \Delta[n] \times \{1\} \ar[d] & \Delta[n] \times \Delta[1] \ar[r] & B \\
}
\end{array}
\]

has a solution.
(v) Any 1-simplex $\beta : b \to pe$ in $B$ admits a lift $\chi : e' \to e$ in $E$ so that any lifting problem for $n \geq 2$

\[
\begin{array}{c}
\Delta[1] \xrightarrow{\chi} \Lambda''[n] \xrightarrow{\oplus_{\Delta[n] \times 1}} E \\
\downarrow \quad \downarrow p \\
\Delta[n] \xrightarrow{p} B
\end{array}
\]

(F.4.3)

has a solution.

Condition (v) appears to be mildly stronger than [74, 2.4.2.1], which only requires that $p$ is an inner fibration with the lifting property (F.4.3), but it follows easily that any such $p$ must be an isofibration; see Exercise F.4.i.

PROOF. Condition (i) is a repackaging of the original Definition 5.2.1 with the induction and conservativity properties of the $p$-cartesian natural transformations of Definition 5.1.1 strengthened to include the observation of Lemma 5.1.10 and the global requirement that these properties be inherited by restrictions of $p$-cartesian natural transformations. Modulo this translation, the equivalence of (i), (ii), and (iii) is proven in Theorem 5.2.10.

It remains to verify the equivalence between any of these synthetic conditions and the corresponding analytic ones. We'll demonstrate that (iii)$\iff$(iv) and (iv)$\iff$(v).

By Lemma F.3.1, the isofibration $k$ admits a right adjoint right inverse if and only if any 1-simplex $\beta : b \to pe$ in $B$ admits a lift $\chi : e' \to e$ in $E$ with the lifting property

\[
\chi
\begin{array}{c}
1 \xrightarrow{[n]} \partial \Delta[n] \xrightarrow{\chi} E^2 \\
\downarrow \quad \downarrow k \\
\Delta[n] \xrightarrow{k} \text{Hom}_B(B, p)
\end{array}
\]

(F.4.4)

for $n \geq 1$. Since the isofibration $k$ is the Leibniz cotensor of $p$ with the inclusion $1 : \Delta[0] \to \Delta[1]$, this lifting property is equivalent to the transposed lifting property

\[
\begin{array}{c}
\Delta[1] \xrightarrow{[n] \times \text{id}} \partial \Delta[n] \times \Delta[1] \xrightarrow{\chi} \Delta[n] \times \{1\} \xrightarrow{\oplus_{\Delta[n] \times 1}} E \\
\downarrow \quad \downarrow p \\
\Delta[n] \times \Delta[1] \xrightarrow{p} B
\end{array}
\]

again for $n \geq 1$, proving the equivalence between (iii) and (iv).

Now we'll show that the lifting property (F.4.3) assumed in (v) suffices to solve this lifting problem. Our task is to find lifts along $p$ for each of the $n+1$ shuffles of $\Delta[n] \times \Delta[1]$. We number these shuffles $0, \ldots, n$ starting from the closed end of the cylinder. Proceeding inductively for $k < n$, we choose a lift for the $k$th shuffle by filling a $\Lambda^{k+1}[n+1]$ horn, which can be done since $p$ is an isofibration between quasi-categories. To lift the $n$th shuffle, we're required to fill a $\Lambda^{n+1}[n+1]$ horn whose final $[n, n+1]$ edge is $\chi$, which can be done with the lifting property (F.4.3). This proves that (v)$\Rightarrow$(iv).
The converse implication holds on account of the retract diagram

\[
\begin{array}{ccl}
\Delta[1] & \xrightarrow{[n] \times \text{id}} & \Lambda^{n+1}[n + 1] \\
\downarrow & & \downarrow \\
\Delta[n + 1] & \xrightarrow{i} & \Delta[n] \times 
\end{array}
\]

\[
\Delta[n + 1] \leftarrow \partial \Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} \rightarrow \Lambda^{n+1}[n + 1]
\]

\[\text{(F.4.5)}\]

in which \(i: \Delta[n + 1] \hookrightarrow \Delta[n] \times \Delta[1]\) is the inclusion of the last shuffle at the open end of the cylinder and \(\rho: \Delta[n] \times \Delta[1] \rightarrow \Delta[n + 1]\) is the projection that collapses the closed end of the cylinder to a point. In coordinates:

\[
i(i) := \begin{cases} (i,0) & 0 \leq i \leq n \\ (n,1) & i = n + 1 \end{cases}
\]

and

\[
\rho(i,j) := \begin{cases} i & j = 0 \\ n + 1 & j = 1 \end{cases}
\]

By Lemma C.2.3 it’s now clear that the lifting property (F.4.2) implies the lifting property (F.4.3). □

The proof of Proposition F.4.1 demonstrated that the lifting properties of (iv) and (v) define equivalent analytic characterizations of what it means for a 1-simplex in the domain of an isofibration \(p: E \rightarrow B\) to be “\(p\)-cartesian,” see also [74, 2.4.1.8]. A priori this analytic definition of what it means for an edge in the domain of an isofibration \(p\) between quasi-categories to be \(p\)-cartesian appears to be significantly stronger than our synthetic Definition 5.1.1 and indeed this is the case—unless \(p\) is a cartesian fibration, in which case this weaker universal property, miraculously, turns out to be strong enough.

F.4.6. PROPOSITION. Fix \(p: E \rightarrow B\) an isofibration of quasi-categories and consider a 1-simplex \(\chi: e' \rightarrow e\) in E. The following are equivalent and characterize when \(\chi\) is \(p\)-cartesian:

(i) The induced map to the pullback in the square

\[
\begin{array}{ccc}
E_{/e'} & \rightarrow & E_{/e} \\
p \downarrow & & \downarrow p \\
B_{/p e'} & \rightarrow & B_{/p e}
\end{array}
\]

is a trivial fibration.

(ii) Any lifting problem for \(n \geq 2\)

\[
\Delta[1] \rightarrow \Lambda^n[n] \rightarrow E \\
\downarrow \chi \rightarrow \downarrow p \\
\Delta[n] \rightarrow B
\]

has a solution.
(iii) Any lifting problem for \( n \geq 1 \)

\[
\begin{array}{cccccc}
\Delta[1] & \xrightarrow{\partial} & \partial \Delta[n] \times \Delta[1] & \cup & \Delta[n] \times \{1\} & \xrightarrow{\Delta[n] \times \{1\}} & E \\
\downarrow & & \downarrow & & \downarrow p & & B \\
\Delta[n] \times \Delta[1] & & \Delta[n] \times \{1\} & & & & \\
\end{array}
\]

has a solution.

If \( p : E \to B \) is known to be a cartesian fibration, then the following criterion also characterizes the \( p \)-cartesian edges \( \chi : e' \to e \).

(iii) Any lifting problem for \( n \geq 1 \)

\[
\begin{array}{ccccccc}
\Delta[1] & \xrightarrow{\partial} & \partial \Delta[n] \times \Delta[1] & \cup & \Delta[n] \times \{1\} & \xrightarrow{\Delta[n] \times \{1\}} & E \\
\downarrow & & \downarrow & & \downarrow & & B \\
\Delta[n] \times \Delta[1] & & \Delta[n] \times \{1\} & & & & \\
\end{array}
\]

has a solution.

If \( p : E \to B \) is known to be a cartesian fibration, then the following criterion also characterizes the \( p \)-cartesian edges \( \chi : e' \to e \).

(iv) \( \bullet \) induction: Given any 1-simplices \( \tau : e'' \to e' \) in \( E \) and \( \gamma : pe'' \to pe' \) in \( B \) that bound a 2-simplex

\[
\begin{array}{cccccc}
pe'' & \xrightarrow{p\tau} & pe & \xrightarrow{p\gamma} & pe' \\
\end{array}
\]

in \( B \), there exists a lift \( \bar{\gamma} : e'' \to e' \) of \( \gamma \) that bounds a 2-simplex

\[
\begin{array}{cccccc}
e'' & \xrightarrow{\tau} & e & \xrightarrow{\gamma} & e' \\
\end{array}
\]

in \( E \).

\[
\begin{array}{cccccc}
e'' & \xrightarrow{\tau} & e & \xrightarrow{\gamma} & e' \\
\eta : \bar{e}' & \xrightarrow{\chi} & e' & \in & hE \\
\downarrow & & \downarrow & & \downarrow p_* \\
pe'' & \xrightarrow{p\tau} & pe & \xrightarrow{p\gamma} & pe' & \in & hB \\
\end{array}
\]

- \( \bullet \) conservativity: Any fibered endomorphism of \( \chi \) is invertible: if \( \zeta : e' \to e' \) is a 1-simplex in \( E \) so that there exists a 2-simplex

\[
\begin{array}{cccccc}
e' & \xrightarrow{\chi} & e & \xrightarrow{\zeta} & e' \\
\end{array}
\]

in \( E \) and \( p\zeta \) is an isomorphism, then \( \bar{\zeta} \) is an isomorphism.

PROOF. By the adjunction of Proposition 4.2.5, the lifting property that characterizes the trivial fibration of (i)

\[
\begin{array}{cccccc}
\partial \Delta[n] & \xrightarrow{\partial} & E_{/\chi} & \xrightarrow{p} & B_{/\chi} \times E_{/e} \\
\downarrow & & \downarrow & & \downarrow \\
\Delta[n] & \xrightarrow{p} & B_{/pe} \times E_{/e} \\
\end{array}
\]
for \( n \geq 0 \) transposes to the lifting property of (ii), as argued in the proof of Proposition F.1.1. The proof of Proposition F.4.1(iv)\( \Leftrightarrow \) (v) demonstrates that (ii)\( \Leftrightarrow \) (iii).

Finally, in the case where \( p: E \to B \) is known to be a cartesian fibration, Lemma 5.5.5 proves that the synthetically \( p \)-cartesian natural transformations, satisfying the weak universal property of (iv), coincide with the class of \( p \)-\textit{cartesian 1-arrows} introduced in Definition 5.5.4, namely those vertices in the essential image of the right adjoint right inverse \( \bar{r}: \text{Hom}_B(B, p) \to E^2 \) to \( k: E^2 \to \text{Hom}_B(B, p) \). By Lemma F.3.1, these vertices have a lifting property (F.4.4), which we’ve just seen transposes to the lifting property of (iii). Thus, in the case where \( p \) is a cartesian fibration, (iv) is as strong as the a priori higher-dimensional lifting properties (i), (ii), and (iii).

We now extend the notion of cartesian edge from Definition 5.5.4 to define a \textit{cartesian cylinder} to describe a variant of the lifting properties appearing in Proposition F.4.6.

\textbf{F.4.7. Definition (cartesian cylinders).} Suppose that \( p: E \to B \) is a cartesian fibration of quasi-categories and that \( X \) is any simplicial set. We say that a cylinder \( e: X \times \Delta[1] \to E \) is \textit{pointwise} \( p \)-\textit{cartesian} if and only if for each 0-simplex \( x \in X \) it maps the 1-simplex \((x \cdot \sigma_0, \text{id}_{[1]}) : (x, 0) \to (x, 1)\) to a \( p \)-cartesian arrow in \( E \).

\textbf{F.4.8. Lemma.} Let \( p: E \to B \) be a cartesian fibration of quasi-categories. A cylinder \( e: X \times \Delta[1] \to E \) is pointwise \( p \)-cartesian if and only if its dual \( e: \Delta[1] \to E^X \) defines a \( p^X \)-cartesian arrow for the cartesian fibration \( p^X : E^X \to B^X \).

\[ e \]

\textbf{Proof.} First note that Corollary 5.2.15 implies that \( p^X : E^X \to B^X \) is a cartesian fibration. To prove the stated equivalence, note that a vertex is in the essential image of \( \bar{r}: \text{Hom}_B(B, p) \to E^2 \) if and only if it transposes to a diagram \( X \to E^2 \) whose vertices land in the essential image of \( \bar{r}: \text{Hom}_B(B, p) \to E \).

Thus, the exponentiated functor \( p^X : E^X \to B^X \) is a cartesian fibration whose cartesian arrows are the pointwise \( p \)-cartesian cylinders. It follows that for all \( f: X \to Y \) restriction along \( f \) defines a cartesian functor of cartesian fibrations:

\[
\begin{array}{ccc}
E^Y & \to & E^X \\
\downarrow & & \downarrow \\
B^Y & \to & B^X
\end{array}
\]

We give one further lifting property characterization of the \( p \)-cartesian edges for an isofibration \( p: E \to B \) between quasi-categories that will be used in the body of the text.

\textbf{F.4.9. Lemma.} Let \( X \hookrightarrow Y \) be a simplicial subset of a simplicial set \( Y \).

(i) Any lifting problem for \( n \geq 0 \)

\[
X \times \Delta[1] \cup Y \times [1] \xrightarrow{e} E
\]

\[
Y \times \Delta[1] \xrightarrow{b} B
\]

with the property that the cylinder \( X \times \Delta[1] \subseteq X \times \Delta[1] \cup Y \times [1] \) \( \to E \) is pointwise \( p \)-cartesian admits a solution \( \bar{e} \) which is also pointwise \( p \)-cartesian.
(ii) Any lifting problem for $n \geq 1$

$$
\begin{array}{ccc}
X \times \Delta[n] \cup Y \times \Lambda^n[n] & \xrightarrow{e} & E \\
\downarrow & & \downarrow \rho \\
Y \times \Delta[n] & \xrightarrow{b} & B \\
\end{array}
$$

in which the cylinder $Y \times \Delta^{[n-1,n]} \subseteq X \times \Delta[n] \cup Y \times \Lambda^n[n] \xrightarrow{e} E$ is pointwise $p$-cartesian admits a solution $\tilde{e}$.

**Proof.** The Leibniz tensor with $X \hookrightarrow Y$ defines a functor $s\text{Set}^2 \to s\text{Set}^2$ that preserves the retract diagram (F.4.5), so the lifting property (ii) follows from (i). In turn, the lifting property (i) follows inductively from Proposition F.4.6(iii) combined with the fact that any monomorphism $X \hookrightarrow Y$ can be decomposed as a sequential composite of pushouts of coproducts of inclusions $i_n : \partial \Delta[n] \hookrightarrow \Delta[n]$, and by Proposition C.2.9(vi), the pushout product with $\{1\} \hookrightarrow \Delta[1]$ is then similarly a sequential composite of pushouts of coproducts of the pushout products $\partial \Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} \hookrightarrow \Delta[n] \times \Delta[1]$.

A similar argument proves the following result.

**F.4.10. Lemma.** A cocartesian fibration $q : E \rightarrow A$ of quasi-categories admits a right adjoint right inverse $t : A \rightarrow E$ if and only if for each object $a \in A$ the fiber $E_a$ over that object has a terminal object.

**Proof.** To prove necessity, consider the following commutative diagram:

$$
\begin{array}{ccc}
1 & \xrightarrow{[n]} & \partial \Delta[n] & \xrightarrow{E_a} & E \\
\downarrow & & \downarrow y & & \downarrow q \\
\Delta[n] & \xrightarrow{1} & A \\
\end{array}
$$

Under our assumption that $q$ has a right adjoint right inverse $t$ we may apply the lifting condition depicted in equation F.3.2 of Lemma F.3.1 to show that the outer composite square has a lifting (the dotted arrow) and then apply the pullback property of the right hand square to obtain a lifting for the left hand square (the dashed arrow). This lifting property of the left hand square shows that $ta$ is a terminal object in $E_a$.

To establish sufficiency, we start by taking the object $ta \in E$ to be the terminal object in the fiber $E_a$ for each object $a \in A$. Now by Lemma F.3.1 our desired result follows if we can show that each lifting problem

$$
\begin{array}{ccc}
1 & \xrightarrow{[n]} & \partial \Delta[n] & \xrightarrow{y} & E \\
\downarrow & & \downarrow q \\
\Delta[n] & \xrightarrow{x} & A \\
\end{array}
$$

has a solution. Consider the order preserving function $k : [n] \times [1] \rightarrow [n]$ defined by $k(i,0) := i$ and $k(i, 1) := n$. Taking nerves, this gives rise to a simplicial map $k : \Delta[n] \times \Delta[1] \rightarrow \Delta[n]$ and it is easy
to check that this restricts to a simplicial map $k: \Delta[n] \times \Delta[1] \to \Delta[n]$ which we may compose with $x: \Delta[n] \to A$ to give (a representative of) a 2-cell

$$
\partial \Delta[n] \xrightarrow{y} E \\
\downarrow \cong \gamma \\
1 \xrightarrow{a} A
$$

with the property that $k[n]$ is the identity 2-cell on $a$. Now we may take a cocartesian lift $\chi: y \Rightarrow u$ of $\kappa$ and by construction the image of $u: \Delta[n] \to E$ is contained entirely in the fiber $E_a \subseteq E$. What is more, we know that $\chi[n]$ is an isomorphism since we have, by pre-composition stability of cocartesian 2-cells, that it is a cocartesian lift of the identity 2-cell on $a$. Consequently, we see that $u[n]$ is a terminal object of $E_a$, since it is isomorphic to $ta$, and it follows that we may apply its universal property to extend $u: \partial \Delta[n] \to E_a$ to a simplex $v: \Delta[n] \to E_a$.

We may combine (a representative of) the 2-cell $\chi$ with $v$ to assemble the upper horizontal map in the following commutative square:

$$
\begin{array}{ccc}
\partial \Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} & \xrightarrow{\chi} & E \\
\downarrow \dashrightarrow & & \downarrow q \\
\Delta[n] \times \Delta[1] & \xrightarrow{\chi[n]} & A
\end{array}
$$

Now we can construct a solution for this lifting problem by successively picking fillers for each of the non-degenerate $(n + 1)$-simplices in $\Delta[n] \times \Delta[1]$. These are guaranteed to exist for the first $n - 1$ of those because $q$ is an isofibrations and they entail the filling of an inner horn. To obtain a filler for the last one we need to fill an outer horn, but observe that its final edge maps to an isomorphism of $E$, since it is the image of $\chi[n]$, and so it too has a filler. Finally on restricting the resulting map $\ell: \Delta[n] \times \Delta[1] \to E$ to the initial end of the cylinder that is its domain, we obtain an $n$-simplex $\Delta[n] \to E$ which is easily seen to be a solution to the original lifting problem in (F.4.11) as required. □

A final result demonstrates that discrete cocartesian and discrete cartesian fibrations between quasi-categories coincide with the classes of left fibrations and right fibrations introduced by Joyal [59].

F.4.12. Proposition. For an isofibration $p: E \to B$ between quasi-categories, the following are equivalent and define what it means for $p$ to be a discrete cartesian fibration:

(i) The map $p: E \to B$ is a cartesian fibration whose fibers are Kan complexes.

(ii) Every 2-cell $\beta: b \Rightarrow pe$ in the homotopy 2-category of quasi-categories has an essentially unique lift: given $\chi: e' \Rightarrow e$ and $\psi: e'' \Rightarrow e$ so that $p\chi = p\psi = \beta$, then there exists an isomorphism $\gamma: e'' \Rightarrow e'$ with $\chi \cdot \gamma = \psi$ and $p\gamma = \id$.

(iii) The induced functor $k: E^2 \to \text{Hom}_B(B, p)$ is a trivial fibration.

(iv) For $n \geq 0$ and $0 < k \leq n$ any lifting problem

$$
\Lambda^k[n] \xrightarrow{\chi} E \\
\downarrow \cong \gamma \\
\Delta[n] \xrightarrow{\delta} B
$$

has a solution.
Proof. The first characterization (i) is a reinterpretation of the original Definition 5.6.3 using Proposition 12.2.3, which says that an isofibration \( p : E \rightarrow B \) defines a discrete object in \( \mathbf{QCat}_B \) if and only if its fibers are Kan complexes. The equivalence of (i) with (ii) is proven in Proposition 5.6.5, while the equivalence of (i) with (iii) is proven in Proposition 5.6.8.

We conclude by demonstrating the equivalence of (iii) and (iv). Recall from Remark 5.2.12, that the canonical functors \( k : E^2 \rightarrow \mathbf{Hom}_B(B, p) \) can be constructed as the Leibniz cotensor of the mono-morphism \( 1 : 1 \rightarrow 2 \) with the trivial fibration \( p : E \rightarrow B \). By adjunction, \( k \) is a trivial fibration if and only if the lifting problem below-right has a solution

\[
\begin{array}{ccc}
\partial \Delta[n] & \rightarrow & E^2 \\
\downarrow & & \downarrow \\
\Delta[n] & \rightarrow & \mathbf{Hom}_B(B, p)
\end{array} \quad \Longleftrightarrow 
\begin{array}{ccc}
\partial \Delta[n] \times \Delta[1] \cup \Delta[n] \times \{1\} & \rightarrow & E \\
\downarrow & & \downarrow \\
\Delta[n] \times \Delta[1] & \rightarrow & B
\end{array}
\]

By Proposition D.3.9, if \( p : E \rightarrow B \) is a right fibration, satisfying condition (iv), then the lifting problem above-right admits a solution and hence \( k : E^2 \rightarrow \mathbf{Hom}_B(B, p) \) is a trivial fibration proving (iii). Conversely, for \( 0 < k \leq n \) the horn inclusion \( \Lambda^k[n] \hookrightarrow \Delta[n] \) is a retract

\[
\begin{array}{ccc}
\Delta[n] & \rightarrow & \Delta[n] \times \Delta[1] \\
\downarrow & & \downarrow \\
\Lambda^k[n] & \rightarrow & \Lambda^k[n] \times \{1\}
\end{array} \quad \text{where} \quad r(i, 0) = i, \quad r(i, 1) = \begin{cases} i & i \neq k-1 \\ k & i = k-1 \end{cases}

Thus, to solve the lifting problem postulated by (iv), it suffices to show that \( p \) lifts against the pushouts products \( (\Lambda^k[n] \hookrightarrow \Delta[n]) \times (\{1\} \hookrightarrow \Delta[1]) \), which transposes to a lifting problem between the mono-morphism \( \Lambda^k[n] \hookrightarrow \Delta[n] \) and \( k : E^2 \rightarrow \mathbf{Hom}_B(B, p) \). If (iii) holds and \( k \) is a trivial fibration, then this constructs the desired lift. \[\square\]

Exercises.

F.4.i. Exercise. Suppose \( p : E \rightarrow B \) is an inner fibration between quasi-categories so that any 1-simplex \( \beta : b \rightarrow pe \) in \( B \) admits a lift \( \chi : e' \rightarrow e \) in \( E \) so that any lifting problem for \( n \geq 2 \)

\[
\begin{array}{ccc}
\Delta[1] & \rightarrow & \Lambda^n[n] \\
\downarrow & \Rightarrow & \downarrow \\
\Delta[n] & \rightarrow & B
\end{array}
\]

has a solution. Show that \( p \) is an isofibration.

F.5. Adjunctions

The comparison between the analytic and synthetic definitions of adjunction between quasi-categories is somewhat more subtle as these are typically presented with different data. The synthetic definition, originally due to Joyal [61], of an adjunction involves two specified functors \( f : B \rightarrow A \) and \( u : A \rightarrow B \), together with specified maps \( \eta : B \times \Delta[1] \rightarrow B \) and \( \eta : A \times \Delta[1] \rightarrow A \) up to homotopy in \( B^B \) or \( A^A \), together with 2-simplices in the quasi-categories \( B^A \) and \( A^B \) that witness the triangle

\[
\begin{array}{ccc}
\Delta[1] & \rightarrow & \Lambda^n[n] \\
\downarrow & \Rightarrow & \downarrow \\
\Delta[n] & \rightarrow & B
\end{array}
\]
equalities. By contrast, the analytic notion, due to Lurie [74, 5.2.2.1], is defined to be an isofibration\(^2\) that is both a cartesian fibration and a cocartesian fibration equipped with specified equivalences \(M_0 \simeq B\) and \(M_1 \simeq A\).

Since Proposition 2.1.13 demonstrates that the synthetic notion of adjunction is equivalence-invariant, we simplify our notation somewhat and let \(B\) and \(A\) denote the fibers over 0 and 1 respectively of the isofibration \(M \rightarrow \Delta[1]\). Our aim in this section is to show that from a cocartesian and cartesian fibration \(M \rightarrow \Delta[1]\), one can extract an adjunction between \(B\) and \(A\), with the adjoint functors determined uniquely up to isomorphism, and conversely from a 2-categorical adjunction, one can construct a corresponding correspondence \(M \rightarrow \Delta[1]\), which is unique up to fibered equivalence.

F.5.1. Proposition. Let \(M\) be a quasi-category equipped with a map \(M \rightarrow \Delta[1]\) that is both a cocartesian fibration and cartesian fibration. Then
- the fibers \(B := M_0\) and \(A := M_1\) and
- the functors \(f : B \rightarrow A\) and \(u : A \rightarrow B\) defined by the cocartesian and cartesian lift, respectively, of the generic arrow in \(\Delta[1]\)

define an adjunction

\[
\begin{array}{ccc}
A & \xleftarrow{f} & B \\
\downarrow{u} & & \downarrow{f} \\
\end{array}
\]

Proof. This is a special case of Proposition 5.4.7. We recall the construction of \(f\) and \(u\) and leave the rest of the details to that result and Remark 5.2.9. Let \(\chi\) denote a cocartesian lift of the generic arrow in \(\Delta[1]\) whose domain is the inclusion \(B \hookrightarrow M\) of the fiber over 0. The codomain of this lifted arrow lands in the fiber over 1 and thus factors uniquely through the inclusion \(A \hookrightarrow M\) of that fiber:

\[
\begin{array}{ccc}
B & \rightarrow & M \\
\downarrow{0} & & \downarrow{f} \\
1 & \rightarrow & \Delta[1] \\
\end{array}
\]

This factorization defines the functor \(f : B \rightarrow A\). Since cocartesian lifts of a fixed arrow are unique up to isomorphism, this proves that the left adjoint \(f\) is unique up to isomorphism as claimed. The construction of the right adjoint \(u : A \rightarrow B\) is dual, involving a cartesian lift of the generic arrow in \(\Delta[1]\). \(\square\)

The converse makes use of something we call the quasi-categorical collage construction.

F.5.2. Definition (the quasi-categorical collage construction). For any cospan \(f : A \rightarrow C\) and \(g : B \rightarrow C\) of quasi-categories, define a simplicial set \(\text{col}(f, g)\) by declaring that

\[
\text{col}(f, g)_n = \left\{ \left( \Delta[i] \xrightarrow{a} A, \Delta[j] \xrightarrow{b} B, \Delta[n] \xrightarrow{c} C \right) \bigg|\begin{array}{l}
\varepsilon_{\{0, \ldots, i\}} = f(a), \quad i, j \geq -1, \\
\varepsilon_{\{n-i, \ldots, n\}} = g(b), \quad i + j = n - 1.
\end{array} \right\}
\]

\(^2\)The nitpicker might note that Lurie only requires an inner fibration, but any inner fibration over \(\Delta[1]\) is automatically an isofibration. In fact, so long as \(M\) is a quasi-category, any simplicial map \(M \rightarrow \Delta[1]\) is automatically an isofibration.
with the convention that conditions indexed by $\Delta[-1]$ are empty (or that each simplicial set is terminally augmented). There are simplicial maps

\[
\begin{array}{ccc}
B & \xleftarrow{\delta} & \text{col}(f, g) & \xleftarrow{\rho} & A \\
\downarrow & & \downarrow \rho & & \downarrow \\
\{1\} & \xleftarrow{\iota} & \Delta[1] & \xleftarrow{\iota} & \{0\}
\end{array}
\]

the top ones being the evident inclusions. The map $\rho$ is defined to send an $n$-simplex $(a: \Delta[i] \to A, b: \Delta[j] \to B, c: \Delta[n] \to C)$ to the $n$-simplex $[n] \to [1]$ that carries $0, \ldots, i$ to 0 and $i + 1, \ldots, n$ to 1. Note that the fiber of $\rho$ over 0 is isomorphic to $A$ while the fiber of $\rho$ over 1 is isomorphic to $B$.

As was our custom for two-sided fibrations and modules, we customarily write $B + A \hookrightarrow \text{col}(f, g)$ for the inclusions of the fibers over 1 and 0 — with the fiber over 1 on the left and the fiber over 0 on the right. This positions the covariantly-acting quasi-category on the “left” and the contravariantly-acting quasi-category on the “right.”

F.5.3. Lemma. The map $\rho: \text{col}(f, g) \to \Delta[1]$ is an inner fibration. In particular, the simplicial set $\text{col}(f, g)$ is a quasi-category.

Proof. Since the fibers of $\rho$ over 0 and 1 are the quasi-categories $A$ and $B$, it suffices to consider inner horns

\[
\begin{array}{ccc}
\Lambda^k[n] & \xrightarrow{\alpha} & \text{col}(f, g) \\
\downarrow & & \downarrow \rho \\
\Delta[n] & \xrightarrow{\alpha} & \Delta[1]
\end{array}
\]

for which $\alpha: [n] \to [1]$ is a surjection. Suppose $\alpha$ carries $0, \ldots, i$ to 0 and $i + 1, \ldots, n$ to 1. Note that for any $0 < k < n$, the faces $[0, \ldots, i]$ and $[i + 1, \ldots, n]$ of $\Delta[n]$ belong to the horn $\Lambda^k[n]$. In particular, the map $\Lambda^k[n] \to \text{col}(f, g)$ identifies simplices $a: \Delta[i] \to A$ and $\Delta[n-i-1] \to B$ together with a horn $\Lambda^k[n] \to C$ whose initial and final faces are the images of these simplices under $f: A \to C$ and $g: B \to C$. Since $C$ is a quasi-category this horn admits a filler $c: \Delta[n] \to C$ and the triple $(a, b, c)$ defines an $n$-simplex in $\text{col}(f, g)$ solving the lifting problem.

We write $\text{col}(f, B)$ for the collage of $f: A \to B$ with the identity on $B$.

F.5.4. Lemma. For any $f: A \to B$, the map $\rho: \text{col}(f, B) \to \Delta[1]$ is a cocartesian fibration.

Proof. To prove the claim, we need only specify cocartesian lifts of the non-degenerate 1-simplex of $\Delta[1]$ and demonstrate that these edges have the corresponding universal property. To that end, for any vertex $a \in A_0$, let $\chi_a: \Delta[1] \to \text{col}(f, B)$ be the 1-simplex

\[
\chi_a := (a: \Delta[0] \to A, fa: \Delta[0] \to B, fa \cdot \sigma^0: \Delta[1] \to B),
\]
defined by the copy degenerate edge at \( fa \in B_0 \) lying over the 1-simplex in \( \Delta[1] \). To show that \( \chi_a \) is \( \rho \)-cocartesian, we must construct fillers for any left horn

\[
\begin{array}{ccc}
\Delta[1] & \xrightarrow{\chi_a} & \Lambda^0[n] \\
\downarrow & & \downarrow \rho \\
\Delta[n] & \xrightarrow{\beta} & \Delta[1]
\end{array}
\]

whose initial edge is \( \chi_a \). Note that this condition implies that the bottom map \( \beta \colon [n] \to [1] \) carries 0 to 0 and the remaining vertices to 1. The map \( \Lambda^0[n] \to \text{col}(f, B) \) defines a horn \( \Lambda^0[n] \to B \) in the quasi-category \( B \) whose first edge is degenerate. By Proposition 1.1.14, this “special outer horn” admits a filler \( b \colon \Delta[n] \to B \) and the triple

\[
(a \colon \Delta[0] \to A, b \cdot \delta^0 \colon \Delta^{n-1} \to B, b \colon \Delta[n] \to B)
\]

defines an \( n \)-simplex in \( \text{col}(f, B) \) that solves the lifting problem. \( \square \)

**F.5.5. Proposition.** For any \( f \colon A \to B \) between quasi-categories, the collage \( \text{col}(f, B) \) defines the oplax colimit of \( f \) in \( \mathbf{QCat} \). That is \( \text{col}(f, B) \) defines a cone under the pushout diagram

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
\downarrow \text{id} \times \delta^0 & & \downarrow \tau \\
A \times \Delta[1] & \xrightarrow{k} & \text{col}(f, B)
\end{array}
\]

so that the induced map \( k \) is inner anodyne, and in particular an equivalence in the Joyal model structure.

**Proof.** The map \( k \) is a quotient of the map \( h \), which has the following explicit description. For each \( n \)-simplex \( (a, \alpha) \colon \Delta[n] \to A \times \Delta[1] \) define \( i := |\alpha^{-1}(0)| - 1 \), so that \(-1 \leq i \leq n\). Then \( h \) carries \( (a, \alpha) \) to the \( n \)-simplex of \( \text{col}(f, B) \) corresponding to the triple

\[
(a|_{[0, \ldots, i]} \colon \Delta[i] \to A, f a|_{[i+1, \ldots, n]} \colon \Delta[n-i-1] \to B, f a \colon \Delta[n] \to B)
\]

Note that the composite \( \rho h \colon A \times \Delta[1] \to \Delta[1] \) is the projection.

It remains to present \( k \) as a sequential composite of pushouts of coproducts of inner horn inclusions. To do so, first note that

\[
\text{col}(f, B)_n = A_n \coprod A_{n-1} \times_{B_{n-1}} B_n \coprod \cdots \coprod A_0 \times_{B_0} B_n \coprod B_n
\]

where each map \( B_n \to B_i \) is the initial face map corresponding to \( \{0, \ldots, i\} \hookrightarrow \Delta[n] \). From the perspective of this decomposition, \( P_n \) is the subset containing the sets \( A_n \) and \( B_n \) and the subset of \( A_i \times_{B_i} B_n \) whose component in \( B_n \) is in the image of \( f \). The \( n \)-simplices of \( \text{col}(f, B) \) that remain to be attached correspond to elements of \( A_i \times_{B_i} B_n \), for \( 0 \leq i < n \), that are not in the image of \( f \) in the sense just discussed. Note in particular that \( k \colon P_0 \hookrightarrow \text{col}(f, B)_0 \) is an isomorphism and \( k \colon P_n \hookrightarrow \text{col}(f, B)_n \) is an injection for all \( n \geq 1 \).
To enumerate our attaching maps, we start with the collection of non-degenerate $n$-simplices of $\col(f, B)$ for $n \geq 1$ that are not in the image of $f$ and remove also those elements of $A_i \times B_i B_n$ whose components $b \in B_n$ are in the image of the degeneracy map $\sigma_i: B_{n-1} \to B_n$. Partially order this set of simplices first in the order of increasing $n$ and the in order of increasing index $i$; that is we lexicographically order the collection of pairs $(n, i)$ with $n \geq 1$ and $0 \leq i < n$. We will filter the inclusion $P \hookrightarrow \col(f, B)$ as

$$P \hookrightarrow P_{< (1, 0)} \hookrightarrow P_{< (2, 0)} \hookrightarrow P_{< (2, 1)} \hookrightarrow \cdots \hookrightarrow P_{< (n, i)} \hookrightarrow \cdots \hookrightarrow \colim \cong \col(f, B)$$

where the simplicial set $P_{< (n, i)}$ is built from the previous one by a pushout of a coproduct of inner horns indexed by the set of $n$-simplices $(a, b) \in A_i \times B_i B_n$ with $b$ not in the image of $f$ or $\sigma_i$. The filler for the horn indexed by $(a, b)$ will attach this $n$ simplex to $B_n$ as the missing face of the horn and also the $n+1$ simplex $(a, b \sigma^i) \in A_i \times B_i B_{n+1}$.

Consider a simplex $(a, b) \in A_i \times B_i B_n$ with $b$ not in the image of $f$ or $\sigma_i$. Define a horn

$$\Lambda^{i+1}[n + 1] \longrightarrow P_{< (n, i)}$$

$$\Delta[n + 1] \longrightarrow \col(f, B)$$

For each $0 \leq j < i + 1$, the $\delta^j$-face of the $n + 1$ simplex $(a, b \sigma^j)$ is the $n$-simplex $(a \delta^j, b \sigma^j \delta^j)$, which lies in $P_{< (n, i-1)}$ or in $B \hookrightarrow P$ in the case $i = 0$. For each $i + 1 < j \leq n + 1$, the $\delta^j$-face of the $n + 1$ simplex $(a, b \sigma^i)$ is the $n$-simplex $(a, b \sigma^i \delta^j) = (a, b \delta^i \sigma^j) \in A_i \times B_i B_n$, which was previously attached to $P_{< (n-1, i)}$. So the $\Lambda^{i+1}[n + 1]$ indeed maps to $P_{< (n, i)}$, permitting an inductive construction of the next simplicial set in this sequence as the pushout

$$\coprod \Lambda^{i+1}[n + 1] \longrightarrow P_{< (n, i)}$$

$$\coprod \Delta[n + 1] \longrightarrow \col(f, B)$$

defining $P_{< (n+1, 0)}$ in the case $i = n - 1$ and $P_{< (n, i+1)}$ otherwise.

F.5.6. Theorem. Consider a pair of functors between quasi-categories $f: B \to A$ and $u: A \to B$. Then $f$ is left adjoint to $u$ if and only if the collages $\col(f, A)$ and $\col(B, u)$ are equivalent under $A + B$ and over $\Delta[1]$, in which case $\col(f, A) \to \Delta[1]$ or equivalently $\col(B, u) \to \Delta[1]$ defines both a cocartesian and a cartesian fibration.

Proof. First suppose that $\col(f, A) \cong \col(B, u)$ under $A + B$ and over $\Delta[1]$. By Lemma F.5.4 and Corollary 5.3.1 this means that the map $\col(f, A) \to \Delta[1]$ is both a cocartesian and a cartesian fibration. By Proposition F.5.1 it follows that the 1-arrow in $\Delta[1]$ from 0 to 1 induces an adjunction between the fibers $B$ and $A$. By inspection of that proof, the left adjoint functor so-constructed in the case of the bifibration $\col(f, A) \to \Delta[1]$ is $f$; substituting the equivalent bifibration $\col(B, u) \to \Delta[1]$, we see that the right adjoint is equivalent to $u$.

For the converse, we work in the opposite $\infty$-cosmos $\QCat^{op}$, an $\infty$-cosmos in which “not all objects are cofibrant,” as described in §9. In that context, Proposition F.5.5 proves that $\col(f, A)$ and $\col(B, u)$ construct the contravariant and covariant comma objects associated to the functors $f$ and $u$. 620
If \( f \rightarrow u \) in \( \mathbf{QCat} \) then these functors are also adjoint in \( \mathbf{QCat}^{\text{op}} \) and Proposition 4.1.1 then proves that the commas \( \text{col}(f, A) \) and \( \text{col}(B, u) \) are equivalent under \( A + B \). By construction, this equivalence also lies over \( \Delta[1] \). \( \square \)
