Abstract

In [Wi75], for each \( k \), the \( H \)-space that represents Brown–Peterson cohomology \( BP^k(\cdot) \) was split into indecomposable factors, which have torsion-free homotopy and homology. Here, we do the same for the related spectrum \( P(n) \), by constructing idempotent operations in \( P(n) \)-cohomology \( P(n)^{i_1-i_0}(\cdot) \) in the style of [BJW95]; this relies heavily on the Ravenel–Wilson determination [RW96] of the relevant Hopf ring. The resulting \((i-1)\)-connected \( H \)-spaces \( Y_i \) have free connective Morava \( K \)-homology \( k(n)_*(Y_i) \), and may be built from the spaces in the \( \Omega \)-spectrum for \( k(n) \) using only \( v_n \)-torsion invariants.

We also extend Quillen’s theorem on complex cobordism to show that for any space \( X \), the \( P(n)_* \)-module \( P(n)^*(X) \) is generated by elements of \( P(n)^i(X) \) for \( i \geq 0 \). This result is essential for the work of Ravenel–Wilson–Yagita [RWY98], which in many cases allows one to compute \( BP \)-cohomology from Morava \( K \)-theory.

Introduction

We exploit the close relationship between the connective Morava \( K \)-theory spectrum \( k(n) \), whose coefficient ring is \( k(n)_* = \mathbb{F}_p[v_n] \), and the spectrum \( P(n) \) with \( P(n)_* = \mathbb{F}_p[v_n, v_{n+1}, v_{n+2}, \ldots] \), where \( \mathbb{F}_p \) denotes the field with \( p \) elements. These ring spectra are defined for each prime \( p \) (suppressed from almost all the notation) and integer \( n \geq 0 \). Most of our work generalizes the case \( n = 0 \) (see [Wi75]), where \( k(0) = H(\mathbb{Z}(p)) \), the Eilenberg–Mac Lane spectrum for \( \mathbb{Z}(p) \) (the integers localized at \( p \)), and \( P(0) = BP \), the Brown–Peterson spectrum, with \( BP_* = \mathbb{Z}(p)[v_1, v_2, v_3, \ldots] \).

In §1, we present three groups of results. First, we give a structure theorem for a class of \( H \)-spaces that may be defined entirely in terms of \( k(n) \). Second, starting from \( P(n) \), we construct examples of such \( H \)-spaces which we use to prove our structure theorem. Third, there are consequences for the structure of \( P(n)-(co) \)homology: we find (i) a Quillen-type result, that \( P(n)^*(X) \) is generated as a module by elements.
of \(P(n)^i(X)\) for \(i \geq 0\), (ii) a Landweber-type filtration theorem, and (iii) a bound on the homological dimension of \(P(n)\)-homology.

All these results depend on the Ravenel–Wilson calculation [RW96] of the Hopf ring for \(P(n)\), which encodes the unstable operations in \(P(n)\)-cohomology. All the machinery of [Bo95, BJW95] becomes available, making \(P(n)\) our sixth example of a cohomology theory whose operations we can handle in a uniform manner.

The authors acknowledge the influence of D. C. Johnson and D. C. Ravenel on this paper through their work with us on [BJW95, RW96].

**Notation** We fix throughout a prime \(p\) and an integer \(n > 0\). Because it occurs so frequently, we find it convenient to write \(N = p^n - 1\).

[For completeness, we include the results for \(p = 2\). Modifications are required because: (i) our ring spectra are no longer commutative, and (ii) one of our test spaces, real projective space, has different cohomology. Shorter comments, like this one, are enclosed within square brackets. Longer comments form a subsection. A few proofs are substantial enough to be deferred to a separate paper [Bo].]

All spaces are assumed to be homotopy-equivalent to \(cw\)-complexes. Identity maps and homomorphisms are denoted by \(\text{id}\).

We use much notation and terminology from [BJW95]. A ring spectrum \(E\) defines a homology theory \(E_*(-)\) and a cohomology theory \(E^*(-)\), both multiplicative with coefficient ring \(E_S^* = \pi_S^*\). Then \(E_i(-)\) is represented (on the homotopy category \(\mathcal{Ho}\) of unbased spaces) by the \(i\)-th space \(E_i\) of the \(\Omega\)-spectrum for \(E\).

Because we deal mainly with homology and homotopy groups rather than cohomology, we use homology degrees throughout (unlike [BJW95]), assigning the degree \(i\) to elements of \(E_i(X)\) and \(\pi_i(X)\). This forces elements of \(E^i(X)\) to have degree \(-i\). We thus write \(E_*\) for the coefficient ring, even when working with cohomology; in particular, \(E^i(\text{point}) = E_{-i}\). So the Hazewinkel generator \(v_i\) has degree \(2(p^i - 1)\).

The algebraic suspension \(\Sigma M\) of a graded group \(M\) is a copy of \(M\) with all degrees raised by one: an element \(x \in M_i\) gives rise to \(\Sigma x \in (\Sigma M)_{i+1}\).

As in [RW96], \(E(x, \ldots)\) denotes the exterior algebra on generator(s) \(x, \ldots\), \(P(x, \ldots)\) the polynomial algebra, and \(TP_h(x)\) the truncated polynomial algebra \(P(x)/(x^p)\).

### 1 The main results

**Splittings of \(H\)-spaces** We regard the standard generator \(u_k\) of \(P(n)^*(S^k)\) as a map \(u_k : S^k \rightarrow \underline{P(n)}_k\). We consider spaces \(X\) that satisfy the axioms:

(i) \(X\) is a connected \(H\)-space of finite type (meaning that each homotopy group \(\pi_i(X)\) is finitely generated);

(ii) \(k(n)_i(X)\) is a free \(k(n)_*\)-module (equivalently, has no \(v_n\)-torsion);

(iii) For any \(k > 0\), any map \(S^k \rightarrow X\) factors through the map \(u_k\) to give a map \(\underline{P(n)}_k \rightarrow X\).

Our first theorem classifies these spaces.
Theorem 1.2 Given $n > 0$, the spaces $X$ that satisfy the axioms (1.1) have the following properties:

(a) For each $k > 0$, there is (up to homotopy) a unique $(k-1)$-connected (but not $k$-connected) example $Y_k$ that does not decompose as a product of spaces;

(b) Every $X$ is homotopy equivalent to some product $Y = \prod Y_k$, where the number of copies of each $Y_k$ is finite and is uniquely determined by $X$;

(c) Every retract of $X$ is another example;

(d) Every product of examples is an example, provided it has finite type;

(e) The loop space $\Omega X$ is another example, provided $X$ is simply connected.

Shortly, in Definition 1.10, we shall reveal the spaces $Y_k$ explicitly.

Remark The above decompositions and equivalences are not as $H$-spaces. Nevertheless, no information is lost, because in (b) for example, the given multiplication on $X$ corresponds to some multiplication on $Y$; as we (shall) have complete information on the possible maps $Y \times Y \to Y$, we can in principle detect which of them are $H$-space multiplications.

Part (c) is clear. So is (d), with the help of the K"unneth formula for $k(n)$-homology (as in [Bo95, Thm. 4.2]). Part (e) will follow immediately from (b) and Theorem 1.15. We prove (a) and (b) in §3.

Towers built from $k(n)$ Although axiom (1.1)(iii) is technically convenient, it lacks intuitive content. Here, we replace it by a more appealing axiom. This makes Theorem 1.2 analogous to the results of [Wi75], as we discuss later in this section.

We consider spaces that are built from the spaces $k(n)_i$ in a particularly nice way, using only $v_n$-torsion invariants. We recall that $k(n)_n = \mathbb{F}_p[v_n]$, where $v_n$ has degree $2N = 2(p^n - 1)$.

Definition 1.3 Given a space $Y$, we call a map $z: Y \to k(n)_{q+1}$ a $v_n$-torsion map if, considered as an element of $k(n)\ast(Y)$, it satisfies $v_n^c z = 0$ for some $c$. (We assume $q \geq 0$. Indeed, $z$ must be zero unless $q \geq 2N + 1 = 2p^n - 1$.)

We call a space $X$ a $k(n)$-tower with $v_n$-free homotopy if it is the homotopy limit of a sequence of spaces and maps

$$\ldots \longrightarrow X_3 \longrightarrow X_2 \longrightarrow X_1 \longrightarrow X_0 = \text{point}$$

in which each map $X_i \to X_{i-1}$ (for $i > 0$) is the homotopy fibre of some $v_n$-torsion map $z_i: X_{i-1} \to k(n)_{q(i)+1}$. (We allow the possibility of a finite tower, $X = X_m$ for some $m$, or even a tower having only one stage, $X = X_1 = k(n)_{q(1)}$, as well as the degenerate case where $X$ is contractible.)

A $v_n$-torsion map $z: Y \to k(n)_{q+1}$ necessarily induces the zero homomorphism on homotopy. Then for each $i > 0$ (assuming $X$ is connected, so that $q(i) \geq 1$), the homotopy long exact sequence of $z_i$ reduces to the short exact sequence of groups

$$0 \longrightarrow \Sigma^{q(i)}\mathbb{F}_p[v_n] \longrightarrow \pi_* (X_i) \longrightarrow \pi_* (X_{i-1}) \longrightarrow 0.$$
§1 The main results

Thus \( \pi_* (X) \) is an iterated extension of suspensions of \( \mathbb{F}_p [v_n] \). (Our terminology is abusive to the extent that we do not have a natural action of \( v_n \) on \( \pi_* (X_i) \) for \( i > 1 \).)

We study such towers in more detail in §4 and prove the following equivalence.

**Theorem 1.6** If we replace axiom (iii) in (1.1) by the axiom

(iii)' \( X \) is a \( k(n) \)-tower with \( v_n \)-free homotopy;

we obtain the same class of \( H \)-spaces. Thus Theorem 1.2 remains valid.

**Examples based on** \( P(n) \) The prime ideal

\[
I_n = (p, v_1, v_2, \ldots, v_{n-1}) \subset BP_* = \mathbb{Z}_p [v_1, v_2, v_3, \ldots]
\]

is invariant and therefore of particular interest. (We set \( v_0 = p \), and take \( I_1 = (p) \) and \( I_0 = (0) \).) The spectrum \( P(n) \) is constructed (see §2) to have the quotient ring

\[
P(n)_* = BP_*/I_n = \mathbb{F}_p [v_n, v_{n+1}, v_{n+2}, \ldots]
\]

as its homotopy. In particular, \( P(0) = BP \) and \( P(1) \) is just \( BP \) mod \( p \).

Further, given \( m \geq n \), we kill off the ideal

\[
J_m = (v_{m+1}, v_{m+2}, v_{m+3}, \ldots) \subset P(n)_*
\]

(1.8)

to produce the spectrum we call \( P(n, m) \) (but known to Yosimura [Yo76] as \( BP [n, m+1] \) and to Yagita [Ya76] as \( BP(p, v_1, \ldots, v_{n-1}, v_{m+1}, \ldots) \)), with homotopy

\[
P(n, m)_* = P(n)_*/J_m = \mathbb{F}_p [v_n, v_{n+1}, \ldots, v_m].
\]

It comes equipped with a canonical map \( \rho(m) : P(n) \rightarrow P(n, m) \). These spectra are intimately connected with the spectra \( E(n, m) = v^{-1}_m P(n, m) \), which are essential in Ravenel–Wilson–Yagita [RWY98]. We recognize \( P(n, n) \) as \( k(n) \).

**Remark** Unlike \( I_n \), the ideal \( J_m \) is not at all canonical, as it depends on the choice of the generators \( v_i \) of \( P(n)_* \). Nevertheless, our results are independent of this choice, as we are concerned only with the additive structure of \( P(n, m) \).

The behavior of these spectra depends on the numerical function

\[
g(n, m) = 2(p^n + p^{n+1} + \ldots + p^m),
\]

(1.9)

where it is reasonable to define \( g(n, n-1) = 0 \).

**Definition 1.10** Given \( k > 0 \), we define the \( H \)-space \( Y_k = \overline{P(n, m)}_k \), where the integer \( m \) is defined in terms of equation (1.9) by

\[
g(n, m-1) < k \leq g(n, m).
\]

(1.11)

For convenience, we also define \( Y_0 = \mathbb{F}_p \), viewed as a discrete group.

These are the spaces \( Y_k \) that appear in Theorem 1.2. In particular, \( Y_k = \overline{k(n)}_k \) for \( 0 < k \leq 2p^n \). As the spaces \( P(n)_k \) satisfy the axioms (1.1), they must decompose according to Theorem 1.2(b). We establish the following splittings in §3.
Theorem 1.12 Assume $k \geq 0$. If $k > 0$, define $m$ by equation (1.11); if $k = 0$, take $m = n - 1$. Then we have homotopy decompositions
\[ P(n)_k \simeq Y_k \times \prod_{j > m} Y_{k+2(\rho' - 1)} \] (1.13)
and, for any $h > m$,
\[ P(n,h)_k \simeq Y_k \times \prod_{j = m+1}^h Y_{k+2(\rho' - 1)} \] (1.14)
These are equivalences of $H$-spaces [except in the extreme case when $p = 2$ and $k = g(n,m)$].

We showed in [BW01, Thm. 1.1] that such splittings exist, though without making them explicit as we do here in §3. They are patterned after the splittings of the spaces $BP_k$ in [Wi75], which were recovered explicitly in [BJW95] and are reviewed below.

We note that equation (1.14) reduces to Definition 1.10 when $h = m$.

Remark No such result holds for $P(n,m)_k$ when $k > g(n,m)$, as axiom (1.1)(ii) definitely fails (otherwise this space would contradict Theorem 1.2(b)).

We use equation (1.14) to decompose $\Omega Y_k = P(n,m)_{k-1}$ explicitly.

Theorem 1.15 The loop space $\Omega Y_k$ is given for all $k > 0$ as follows:

(a) If $k$ does not have the form $g(n,q) + 1$ for any $q$, then $\Omega Y_k \simeq Y_{k-1}$;

(b) If $k = g(n,q) + 1$, where $q \geq n - 1$, then $\Omega Y_k \simeq Y_{k-1} \times Y_{k-1+2(\rho'+1-1)}$.

Since $\Omega$ is a right adjoint functor and so preserves products, this gives part (e) of Theorem 1.2. We leave it as an exercise to decompose the negative spaces $P(n)_{-k}$ for $k > 0$, by writing them as $\Omega^{k+1}P(n)_{1}$, and similarly $P(n,m)_{-k}$.

Some history For $n = 0$, the results differ slightly. Recall that $k(0) = H(\mathbb{Z}_{(p)})$, $P(0) = BP$, and (see [Wi75]) $P(0,m) = BP(m)$ has $BP(m)_* = \mathbb{Z}_{(p)}[v_1,v_2,\ldots,v_m]$. Axioms (1.1) (with (iii) replaced by (1.7)) then yield connected $H$-spaces $X$ whose homotopy groups $\pi_k(X)$ and homology groups $H_k(X)$ are all free $\mathbb{Z}_{(p)}$-modules of finite rank. The Postnikov $k$-invariants of such spaces are necessarily torsion elements. Theorem 1.2 remains valid exactly as stated, with $m$ still defined by equation (1.11). However, Theorem 1.12 gives $H$-space equivalences only for $g(0,m-1) < k < g(0,m)$; for $k = g(0,m)$, we have merely a homotopy equivalence. (Of course, $Y_0 = \mathbb{Z}_{(p)}$ rather than $F_p$.) These are the main results of [Wi75] or Theorem 1.16 of [BJW95], and form the motivation for this work.

The structure of $P(n)$-cohomology We extend Quillen’s theorem on complex cobordism to $P(n)$.

Theorem 1.16 For any space $X$, the cohomology $P(n)^*(X)$ is generated, as a $P(n)_*$-module (topologically if $X$ is infinite), by elements of $P(n)^i(X)$ for $i > 0$, together with one element of $P(n)^0(X)$ for each component of $X$. 

This result is essential for the calculations in Ravenel–Wilson–Yagita [RWY98]. One version was stated as Theorem 1.11 of [Ya84], without proof (although the approach suggested is now known not to work). In §8, our machinery of additive unstable operations provides a very short direct proof in terms of an explicit formula.

We also refine Landweber’s filtration theorem. Yoshiura [Yo76, Thm. 3.4] and Yagita [Ya76] both observed that Landweber’s theorem generalizes to stable $P(n)$-cohomology comodules $M$. The only finitely generated invariant prime ideals in $P(n)_*$ are $I_m = (v_n, v_{n+1}, \ldots, v_{m-1})$ for $n \leq m < \infty$ (where $I_n$ is interpreted as $(0)$). We find in §8 that an unstable comodule structure on $M$ (in the sense of [BJW95, Defn. 6.32]) restricts the possible Landweber factors as follows.

**Lemma 1.17** Let $M$ be a $P(n)_*$-module with a single generator $x \in M^k$ (in homology degree $-k$) and annihilator ideal $\text{Ann}(x) = I_m$, where $n \leq m < \infty$, so that

$$M \cong \Sigma^{-k}P(m)_* \cong \Sigma^kP(m)^* \cong \Sigma^k(P(n)^*/I_m).$$

Then $M$ admits an unstable $P(n)$-cohomology comodule structure if and only if $k$ satisfies the appropriate condition (depending on $m$ and $p$):

(i) $k \geq 0$ if $m = n$;
(ii) $k \geq g(n, n) - 1$ if $m = n + 1$;
(iii) $k \geq g(n, m-1) - 1$ if $m \geq n + 2$ and $p$ is odd;
(iv) $k \geq g(n, m-1) - 2$ if $m \geq n + 2$ and $p = 2$;

and this comodule structure is unique.

This leads directly to the filtration theorem.

**Theorem 1.18** Let $M$ be an unstable $P(n)$-cohomology comodule of finite type (each $M^i$ a finitely generated $\mathbb{F}_p$-module) and bounded above ($M^i = 0$ for all $i > i_0$). Then $M$ admits a finite filtration by subcomodules

$$0 = M_0 \subset M_1 \subset \ldots \subset M_h = M$$

in which each quotient $M_i/M_{i-1}$ is a monogenic comodule $\Sigma^{-k_i}P(m_i)_*$ with generator $x_i$, as listed in Lemma 1.17. In particular, $M$ is a finitely presented $P(n)_*$-module.

If, in addition, $M$ is a $P(n)_*$-algebra of any of the forms:

(i) $M = P(n)^*(X)$, for a finite complex $X$;
(ii) $M = \text{Im}[f^*: P(n)^*(Y) \to P(n)^*(X)]$, for a map of spaces $f: X \to Y$, where $X$ is a finite complex;
(iii) A spacelike (see [BJW95, Defn. 7.14]) unstable $P(n)_*$-cohomology algebra;

we may take each $M_i$ to be an invariant ideal in $M$. At the last stage, we may take $x_h = 1$ and $m_h = n$.

Our proof in §8 quotes the method of proof of Theorem 20.11 in [BJW95]. However, here we prove that $M$ is finitely presented, instead of assuming it. (Of course, it has long been known that for finite $X$, $P(n)^*(X)$ is a coherent $P(n)_*$-module and hence finitely presented.) In [ibid.], we overlooked the fact that this modification applies equally well to $BP = P(0)$, as follows. (Again, (i) is not new. However, (ii) is non-trivial and new when $BP^*(Y)$ has phantom classes.)
Theorem 1.19  Let $M$ be an unstable $BP$-cohomology comodule of finite type (each $M^i$ a finitely generated $\mathbb{Z}_{(p)}$-module) and bounded above, for example:

1. $M = BP^*(X)$, for a finite complex $X$;
2. $M = \text{Im}[f^*:BP^*(Y) \to BP^*(X)]$, for a map of spaces $f: X \to Y$, where $X$ is a finite complex.

Then $M$ is a finitely presented $BP_*$-module. □

Homological dimension  Our starting point is the Conner–Floyd Theorem [CF66, Thm. 10.1], that the map of ring spectra from the unitary Thom spectrum $MU$ to the $K$-theory spectrum $K$ determined by the Todd genus induces for finite $X$ an isomorphism of cohomology theories

$$K_* \otimes_{MU} MU^*(X) \xrightarrow{\sim} K^*(X).$$

A far-reaching analogue is the result

$$E(n,m)_* \otimes_{P(n)_*} P(n)^*(X) \cong E(n,m)^*(X), \quad (1.20)$$

where $E(n,m) = v_m^{-1}P(n,m)$. A key ingredient of such results is knowledge of the homological dimension of various (co)homology modules.

The case $m = n$ of (1.20) is due to Morava [Mo85] as part of his structure theorem, and is quoted and reproved in [JW75], as well as by Yagita [Ya76]. The case $n = 0$, along with results on the homological dimension of $BP_*(X)$, was proved by Johnson–Wilson [JW73, Rk. 5.13] by means of the splitting theorem for $BP$ in [Wi75]. Shortly afterwards, Landweber [La76] reproved this case by using cohomology operations instead of the splitting, establishing his exact functor theorem in the process; however, he was unable to recover Corollary 4.4 of [JW73], which gave an upper bound on the homological dimension of $BP_*(X)$. Later, Morava and Yagita [Ya77, Thm. 3.11] showed that $P(n)^*(X)$ is a $BP^*(BP)$-module. Yagita and Yoshimura [Yo76] both used this fact to generalize the exact functor theorem to $P(n)$, which fully includes (1.20), and obtain homological dimension results for $P(n)_*(X)$.

We have now gone full circle, and with our splitting for $P(n)$ in hand, can use the techniques of [JW73] to recover these results as well as (1.20), with the added benefit of the following estimate, which we establish in §5.

Theorem 1.21  Assume that $X$ is a finite complex of dimension less than $g(n,m)/2$. Then the homological dimension of the $P(n)_*$-module $P(n)_*(X)$ is at most $m - n$.

Although the exact functor theorem does not apply, $\rho(m): P(n) \to P(n,m)$ still induces a natural homomorphism of $P(n,m)_*$-modules

$$\overline{\rho(m)}: P(n,m)_* \otimes_{P(n)_*} P(n)^*(X) \longrightarrow P(n,m)^*(X).$$

This is an isomorphism when $X$ is a point, but not in general, as the left side is not a cohomology theory. Classically, as in [JW73], one then asks for which $X$ it is an isomorphism. Instead, we show in §5 that it is always an isomorphism in a certain range of degrees [with no modification if $p = 2$]. Explicitly, its components are

$$\overline{\rho(m)}: P(n)^h(X) \big/ \sum_{j > m} v_j P(n)^{h+2(p^j - 1)}(X) \longrightarrow P(n,m)^h(X). \quad (1.22)$$
Theorem 1.23 Assume that $X$ is finite-dimensional and that $m \geq n > 0$. Then (1.22) is an isomorphism for all $h \leq g(n,m)$, and therefore a $P(n,m)_\ast$-module isomorphism in this range.

In particular, for $m = n$ we have the isomorphism

$$\bar{\rho}(n): P(n)^h(X) / \sum_{j>n} v_j P(n)^{h+2(p^{i-1})}(X) \cong k(n)^h(X)$$

for all $h \leq 2p^n$, which preserves the $v_n$-action in this range.

2 The ring spectrum $P(n)$

As the literature is somewhat conflicted [especially when $p = 2$], we review the construction of $P(n)$ in fair detail. In this section, we work entirely in the graded stable homotopy category $\text{Stab}_\ast$.

The spectrum $P(n)$, so named by Johnson–Wilson [JW75], was based on work of Morava. It may conveniently be constructed directly from the Thom spectrum $MU$ by applying Sullivan–Baas theory [Ba73] to kill off the unwanted generators of $MU_\ast$, as well as $p$ (with no need for localization). (As stable $P(n)_\ast$-cohomology operations act faithfully on $P(n)_\ast$-homology, no information is lost by working in homology.)

It is automatically a $BP$-module spectrum, with an action map $\lambda: BP \wedge P(n) \to P(n)$ that satisfies the usual two module axioms, and the canonical map $BP \to P(n)$ is $BP$-linear. It comes equipped with an exterior algebra $E(Q_0, Q_1, \ldots, Q_{n-1})$ of $BP$-linear operations, where $Q_i$ has homology degree $-2(p^i - 1)$; we write the monomial basis elements as $Q^I = Q^{i_0}_0 \circ Q^{i_1}_1 \circ \ldots \circ Q^{i_{n-1}}_{n-1}$ for each multi-index $I = (i_0, i_1, \ldots, i_{n-1})$, where each $i_r$ is 0 or 1.

The canonical map $\eta: S^0 \to BP \to P(n)$ serves as the unit map of $P(n)$, where $S^0$ denotes the sphere spectrum, but there is no obvious multiplication on $P(n)$. It is known that for $p \neq 2$, there is a unique multiplication $\phi: P(n) \wedge P(n) \to P(n)$ having the following properties:

(i) $\phi$ is $BP$-bilinear;
(ii) $BP \to P(n)$ is multiplicative;
(iii) $\phi$ has $\eta: S^0 \to P(n)$ as two-sided unit;
(iv) $\phi$ is commutative;
(v) $\phi$ is associative;
(vi) Each $Q_i: P(n) \to P(n)$ is a derivation, in the sense that

$$Q_i \circ \phi = \phi \circ (Q_i \wedge \text{id}) + \phi \circ (\text{id} \wedge Q_i): P(n) \wedge P(n) \longrightarrow P(n).$$

Historically, three quite different approaches have been used. First, for $p \neq 2$, Morava [Mo79] used averaging over the symmetric group $\Sigma_2$ to produce idempotent operations in (co)bordism with repeated singularities. These operations yield a canonical multiplication $\phi$ on $P(n)$ that is automatically commutative (cf. Mironov [Mi78, Thm. 4.2]). Associativity by this method involves averaging over $\Sigma_3$ and requires $p \geq 5$ [ibid., Thm. 4.1].
The second method is heavily geometric. Mironov [Mi75] and Shimada–Yagita [SY76] constructed (roughly equivalent) explicit multiplications on $P(n)$ in the Baas bordism context for any prime $p$. These apparently depend on a sequence of choices of Morava manifolds. They automatically satisfy axioms (i), (ii) and (iii). Moreover, Shimada–Yagita [SY76, Thm. 5.25] and Mironov [Mi78, Thm. 2.4] both show that the obstructions to associativity lie in groups that vanish, and also obtain (vi). The disadvantage of this approach is that uniqueness is difficult to handle.

Third, Würgler [Wü77] developed an entirely algebraic cohomological approach in terms of comodules, which leads to the existence of $\phi$ and the following results.

**Lemma 2.3** In the graded stable homotopy category $\text{Stab}_*$:

(a) Any $BP$-linear map $P(n) \to P(n)$, of any degree, can be uniquely written in the form

$$\sum c_I Q^I: P(n) \to P(n),$$

(2.4)

with coefficients $c_I \in P(n)_*$ of the appropriate degrees;

(b) Any $BP$-bilinear map $P(n) \wedge P(n) \to P(n)$, of any degree, can be uniquely written in the form

$$\sum_{I,J} c_{I,J} \phi(Q^I \wedge Q^J): P(n) \wedge P(n) \to P(n),$$

(2.5)

with coefficients $c_{I,J} \in P(n)_*$ of the appropriate degrees;

(c) Any $BP$-trilinear map $P(n) \wedge P(n) \wedge P(n) \to P(n)$, of any degree, can be uniquely written in the form

$$\sum_{I,J,K} c_{I,J,K} \phi(\phi(\phi(Q^I \wedge Q^J) \wedge Q^K)): P(n) \wedge P(n) \wedge P(n) \to P(n),$$

(2.6)

with coefficients $c_{I,J,K} \in P(n)_*$ of the appropriate degrees.

**Proof** Part (a) is a strengthened form of Proposition 3.5 of Würgler [Wü77]. Part (b) is Proposition 4.12 of [ibid.], and (c) is entirely analogous. \qed

**Lemma 2.7** The canonical map $\rho: P(n) \to P(n+1)$ is a map of ring spectra.

**Proof** By a slight generalization of (2.5) (also proved by Würgler), any $BP$-bilinear map $P(n) \wedge P(n) \to P(n+1)$, in particular $\phi(\rho \wedge \rho)$, can be written

$$\sum_{I,J} c_{I,J} \rho \phi(Q^I \wedge Q^J): P(n) \wedge P(n) \to P(n+1),$$

with coefficients $c_{I,J} \in P(n+1)_*$. Since $\phi(\rho \wedge \rho)(\eta \wedge \eta) = \eta$, the sparseness of $P(n+1)_*$ leaves $\rho \phi$ as the only candidate for $\phi(\rho \wedge \rho)$. [This works even for $p = 2$, regardless of the choices of multiplication on $P(n)$ and $P(n+1)$.] \qed

If we write $\phi(\eta \wedge \phi)$ in the form (2.4), the sparseness of $P(n)_*$ yields axiom (iii) [even for $p = 2$], since we know $\phi(\eta \wedge \eta) = \eta$. Then (ii) is a formal consequence of (i), (iii), and the $BP$-linearity of the map $BP \to P(n)$. 

§2  The ring spectrum $P(n)$
Since any $BP$-bilinear multiplication can be written in the form (2.5), the sparseness of $P(n)_*$ ensures that $\phi$ is unique, as long as $p \geq 3$. Further, (iv) holds, since $\phi=T$ also satisfies (i) and (iii), where $T: P(n) \wedge P(n) \to P(n) \wedge P(n)$ denotes the switch map.

We may similarly deduce the associativity of $\phi$, provided $p \geq 5$, by writing $\phi \circ (\text{id} \wedge \phi)$ in the form (2.6). We also obtain (vi), provided $p \geq 3$, by writing $Q_\phi \circ \phi$ in the form (2.5); since $(Q_\phi \circ \phi) \circ (\eta \wedge \text{id}) = Q_\phi = (Q_\phi \circ \phi) \circ (\text{id} \wedge \eta)$, the only candidate is (2.2).

Finally, we should mention that there is now a fourth approach, the brave new ring context of Elmendorf–Kriz–Mandell–May. See [EKMM96] for $p$ odd [or Strickland [St99] for $p = 2$].

The case $p = 2$ It is well known that there is no commutative multiplication on $P(n)$ when $p = 2$. Instead, we see in [Bo] that there are exactly two multiplications that satisfy all the axioms (2.1) except (iv). To make $P(n)$ a ring spectrum, we arbitrarily choose one of the two good multiplications as $\phi$; then the other is its opposite, $\bar{\phi} = \phi \circ T$, which defines the opposite ring spectrum $\bar{P}(n)$. Nassau [Na02, Thm. 3] shows that complex conjugation defines an isomorphism of ring spectra $\Xi: P(n) \cong \bar{P}(n)$.

Mironov [Mi78, Thm. 4.7] computed $\bar{\phi}$ explicitly in the form (2.5) as

$$\bar{\phi} = \phi \circ T = \phi + v_n \phi \circ (Q_{n-1} \wedge Q_{n-1}): P(n) \wedge P(n) \longrightarrow P(n).$$

(2.8)

From now on, we write $Q = Q_{n-1}$, in view of its frequent occurrence.

Products in homology and cohomology We review briefly the various products in $P(n)$-(co)homology. Their properties are familiar enough [except when $p = 2$]. We remind the reader that the operations $Q_\phi$ act on both homology and cohomology.

Given $x \in P(n)^*(X)$ and $y \in P(n)^*(Y)$, we have the cohomology cross product $x \times y \in P(n)^*(X \times Y)$; by taking $Y = X$ and using the diagonal map of $X$, we deduce the cup product $xy \in P(n)^*(X)$, which makes $P(n)^*(X)$ a ring. Given $a \in P(n)_*(X)$ and $b \in P(n)_*(Y)$, we have the homology cross product $a \times b \in P(n)_*(X \times Y)$. All three products are associative. For $p \neq 2$, they are also commutative, in the sense that $T^*(y \times x) = \pm x \times y$, $yx = \pm xy$, and $T_*(b \times a) = \pm a \times b$. By equation (2.2), each $Q_\phi$ is a derivation for all three products.

By taking $X$ as a one-point space, $P(n)^*(Y)$ and $P(n)_*(Y)$ become $P(n)_*$-modules, and both cross products are $P(n)_*$-bilinear [even for $p = 2$; see below].

There is also the scalar or Kronecker product $\langle x, a \rangle \in P(n)_*$ of $x \in P(n)^*(X)$ and $a \in P(n)_*(X)$, which is $P(n)_*$-bilinear [even for $p = 2$; see [Bo]].

The case $p = 2$ There are of course no signs, but the noncommutativity of $\phi$ forces us to watch carefully for any shuffling of copies of $P(n)$. Nevertheless, we find [Bo] that the Künneth and duality formulae continue to hold, exactly as stated in [Bo95].

It is immediate from equation (2.8) that

$$T^*(y \times x) = x \wedge y = x \times y + v_n Qx \wedge Qy \quad \text{in } P(n)^*(X \times Y),$$

(2.9)

where $x \wedge y$ denotes the twisted cross product formed using the opposite multiplication $\bar{\phi}$ on $P(n)$. For cup products, this implies

$$yx = xy + v_n (Qx)(Qy) \quad \text{in } P(n)^*(X),$$

(2.10)
so that $P(n)^*(X)$ is not commutative in general in the ordinary sense. Alternatively, these products are $T_Q$-commutative if we replace the standard commutativity isomorphism $T: A \otimes B \cong B \otimes A$ everywhere by $T_Q: A \otimes B \cong B \otimes A$, defined by

$$T_Q(a \otimes b) = b \otimes a + v_n Qb \otimes Qa \quad \text{in } B \otimes A. \quad (2.11)$$

Similarly, homology is also $T_Q$-commutative, in the sense that

$$T_s(b \times a) = a \boxtimes b = a \times b + v_n Qa \times Qb \quad \text{in } P(n)_*(X \times Y). \quad (2.12)$$

Taking $X$ to be a point shows that the $P(n)_*$-actions on $P(n)^*(Y)$ and $P(n)_*(Y)$ are independent of the choice of $\phi$. In [Bo], we find that $\langle x, a \rangle$ is also independent of this choice.

There is one surprise, on account of the hidden shuffling, proved in [Bo].

**Proposition 2.13** Given $x \in P(n)^*(X)$, $y \in P(n)^*(Y)$, $a \in P(n)_*(X)$, and $b \in P(n)_*(Y)$, we have

$$\langle x \times y, a \times b \rangle = \langle x, a \rangle \langle y, b \rangle + v_n \langle x, Qa \rangle \langle Qy, b \rangle. \quad (2.14)$$

If instead we mix the products, we find

$$\langle x \times y, a \boxtimes b \rangle = \langle x, a \rangle \langle y, b \rangle. \quad (2.15)$$

### 3 Proofs of the main theorems

In this section, we establish Theorems 1.2 and 1.12. More precisely, we reduce them to two key lemmas: Lemma 3.1 provides our main splitting and Lemma 3.8 will imply that our splittings are best possible.

**Splittings** All our splittings are derived from the following splitting.

**Lemma 3.1** For $k \leq g(n, m)$, where $m \geq n$, there is a map

$$\vartheta(m): \overline{P(n, m)}_k \longrightarrow \overline{P(n)}_k$$

that splits the canonical map $\rho(m): \overline{P(n, m)}_k \rightarrow \overline{P(n)}_k$, i.e. $\rho(m) \circ \vartheta(m) \cong \text{id}$. It is a map of $H$-spaces [except when $p = 2$ and $k = g(n, m)$].

We express this in terms of idempotent $P(n)$-cohomology operations in §5.

A short direct proof of Lemma 3.1 is presented in [BW01], based on the bar spectral sequence. For such $k$, we show that $E_* \left( \overline{P(n, m)}_k \right)$ is a quotient of $E_* \left( \overline{P(n)}_k \right)$, first for $E = P(n)$, then for $E = P(n, m)$, and that these are free $E_*$-modules. It follows by duality that $\vartheta(m)$ exists, but its status as an $H$-map is left unclear.

We deduce other useful splittings. The canonical map $\rho(m-1, m): P(n, m) \rightarrow P(n, m-1)$, which kills $v_m$, fits into the exact triangle of spectra

$$P(n, m) \xrightarrow{v_m} P(n, m) \xrightarrow{\rho(m-1, m)} P(n, m-1) \xrightarrow{\delta} P(n, m). \quad (3.2)$$

On homotopy groups, this induces the obvious short exact sequence

$$0 \rightarrow \mathbb{F}_p[v_n, v_{n+1}, \ldots, v_m] \xrightarrow{v_m} \mathbb{F}_p[v_n, v_{n+1}, \ldots, v_m] \rightarrow \mathbb{F}_p[v_n, v_{n+1}, \ldots, v_{m-1}] \rightarrow 0.$$
Unstably, we have the $H$-space fibration

$$P(n,m)_{k+2(p^m-1)} \xrightarrow{v_m} P(n,m)_k \xrightarrow{\rho(m-1,m)} P(n,m-1)_k.$$  

For $k \leq g(n,m-1)$, the composite

$$P(n,m-1)_k \xrightarrow{\theta(m-1)} P(n)_k \xrightarrow{\rho(m)} P(n,m)_k$$

automatically splits $\rho(m-1,m)$, to yield the decomposition

$$P(n,m)_k \cong P(n,m-1)_k \times P(n,m)_{k+2(p^m-1)},$$

where the two injections are (3.3) and $v_m$. This is a decomposition of $H$-spaces [except when $p = 2$ and $k = g(n,m-1)$].

**Proof of Theorem 1.12**  This is completely analogous to the proof of Theorem 1.16 of [BJW95]. Everything we need is contained in the commutative diagram

$$\begin{array}{ccc}
P(n)_{k+2(p^j-1)} & \xrightarrow{v_j} & P(n)_k \\
\rho(j) & & \rho(j) \\
P(n,j)_{k+2(p^j-1)} & \xrightarrow{v_j} & P(n,j)_k
\end{array}$$

of $H$-spaces and canonical $H$-maps, where $j > m$.

With $m$ given by (1.11), we observe that the spaces $Y_k$ and $Y_{k+2(p^j-1)}$ appear in the diagram disguised as $P(n,m)_k$ and $P(n,j)_{k+2(p^j-1)}$. We insert the splittings $	heta(m)$ and $	heta(j)$ from Lemma 3.1 to produce the desired decomposition of $P(n)_k$, as suggested by the decomposition of abelian groups

$$\mathbb{F}_p[v_n, v_{n+1}, v_{n+2}, \ldots] = \mathbb{F}_p[v_n, v_{n+1}, \ldots, v_m] \oplus \bigoplus_{j > m} v_j \mathbb{F}_p[v_n, v_{n+1}, \ldots, v_j].$$

(But we warn that our splittings cannot be expected to induce exactly this decomposition of the coefficient ring $P(n)_*$, and it seems likely that they never do.)

In detail, we map $Y_k$ into $P(n)_k$ by $\theta(m)$, which is an $H$-map [unless $p = 2$ and $k = g(n,m)$], and $Y_{k+2(p^j-1)}$, for each $j > m$, by the $H$-map (in all cases)

$$Y_{k+2(p^j-1)} \xrightarrow{\theta(j)} P(n)_{k+2(p^j-1)} \xrightarrow{v_j} P(n)_k.$$  

We multiply these together, using the $H$-space structure of $P(n)_k$, to form a map $f: W \to P(n)_k$ from the restricted direct product $W$ (the union of all finite subproducts) of the based $Y$-spaces mentioned.

We filter $P(n)_*$ by the ideals $J_j$. We note that $v_j \circ \theta(j)$ induces a homomorphism $P(n,j)_* \to J_{j+1}$ on homotopy groups that induces the quotient isomorphism

$$P(n,j)_* = \mathbb{F}_p[v_n, v_{n+1}, \ldots]/J_j \xrightarrow{v_j} J_{j+1}/J_j.$$  

This is enough to guarantee that $f$ induces an isomorphism on homotopy groups and is thus a homotopy equivalence. Because the connectivities of the $Y$-spaces increase, $W$ is homotopy-equivalent to the desired full product and we have (1.13).
The same method applies to $P(n, h)_k$, with the simplification that the product $W$ is now finite. (One can also produce decompositions like (1.14) directly from the splittings (3.4) by induction on $h$, though the resulting maps are different and far more complicated.)

For $k = 0$, the splitting $\theta(n-1): Y_0 = \mathbb{F}_p \to P(n)_0$ is obvious and unique up to homotopy. We can still use diagram (3.5). □

**Indecomposability** On the other hand, we need to know that $Y_k$ does not split.

**Lemma 3.6** A map $f: Y_k \to Y_k$ is a homotopy equivalence if and only if it induces an isomorphism on the bottom homotopy group $\pi_k(Y_k) \cong \mathbb{F}_p$.

**Corollary 3.7** The space $Y_k$ does not decompose as a product. □

In §12, we prove the following about $P(n)$ and deduce Lemma 3.6 from it.

**Lemma 3.8** Represent an unstable operation $r: P(n)^k(-) \to P(n)^m(-)$, where $k > 0$ and $m > 0$, by the map $r: \overline{P(n)}_k \to \overline{P(n)}_m$. Then the induced homomorphism on homotopy groups

$$r_*: \Sigma^k P(n)_* \cong \pi_* \left( \overline{P(n)}_k \right) \xrightarrow{\pi_*(r)} \pi_* \left( \overline{P(n)}_m \right) \cong \Sigma^m P(n)_*$$

(3.9)

has the properties, for any element $v \in P(n)_*$:

(a) $r_* \Sigma^k (v_n v) = v_n r_* \Sigma^k v$;

(b) $r_* \Sigma^k (v_q v) \equiv v_q r_* \Sigma^k v \mod I_q = (v_n, v_{n+1}, \ldots, v_{q-1})$, provided $k > g(n, q-1)$.

**Construction of maps** Our strategy for proving Theorem 1.2 is to construct enough maps to and from the spaces $\overline{P(n)}_k$.

**Lemma 3.10** If $X$ is a space for which $k(n)_*(X)$ is a free $k(n)_*$-module, then $P(n)_*(X)$ is a free $P(n)_*$-module.

**Proof** Lemmas 4.7 (with $k = m = n$) and 2.1 of Yosimura [Yo76] show that $P(n)_*(X)$ is a flat $P(n)_*$-module. Such modules are free by [ibid., Prop. 1.5]. □

**Lemma 3.11** Let $X$ be a $(k-1)$-connected space with $\pi_k(X)$ a nonzero finite abelian $p$-group and suppose $k(n)_*(X)$ is a free $k(n)_*$-module. Then there exists a map $f: X \to \overline{P(n)}_k$ that induces a nonzero homomorphism $f_*: \pi_k(X) \to \pi_k \left( \overline{P(n)}_k \right) \cong \mathbb{F}_p$ on the bottom homotopy groups.

**Proof** Since $P(n)_*(X)$ is a free $P(n)_*$-module by Lemma 3.10, the universal coefficient theorem [Bo95, Thm. 4.14] gives

$$P(n)_*(X) \cong \text{Hom}_{P(n)_*}^*(P(n)_*(X), P(n)_*)$$

As $X$ is $(k-1)$-connected, $P(n)_k(X) \cong H_k(X; \mathbb{F}_p) \cong \pi_k(X) \otimes \mathbb{F}_p \neq 0$, and it is clear that suitable cohomology classes $f \in P(n)^k(X)$, i.e. maps $f: X \to \overline{P(n)}_k$, exist. □

**Proof of parts (a) and (b) of Theorem 1.2** We first note that for $k > 0$, the space $\overline{P(n)}_k$ satisfies the axioms (1.1). Axiom (i) is clear. Axiom (ii) holds by [RW96].
Axiom (iii) is easy. Take any element $\Sigma^k v \in \Sigma^k P(n) \cong \pi_*(P(n)_k)$, where $v \in P(n)_h$. Viewed as a cohomology class, it is $v u_{k+h} \in P(n)^*(S^{k+h})$. Multiplication by $v$ on $P(n)^*(-)$ is represented by the map we want, $v: P(n)_{k+h} \rightarrow P(n)_k$.

Then $Y_k$, being a retract of $P(n)_k$, also satisfies the axioms. By Corollary 3.7, it is indecomposable. Uniqueness of $Y_k$ and our decompositions will follow from (b), under the assumption that all our $H$-spaces have finite type.

For the induction step in (b), given any $(k-1)$-connected space $X$ that satisfies the axioms, define $m$ by (1.11). Then Lemma 3.11 provides a map

$$h: X \longrightarrow P(m)_k \longrightarrow P(n, m)_k = Y_k$$

that induces a nonzero homomorphism $h_*: \pi_k(X) \rightarrow \pi_k(Y_k) \cong \mathbb{F}_p$. Choose $\alpha \in \pi_k(X)$ such that $h_*\alpha = 1 \in \mathbb{F}_p$; then axiom (iii) provides a map

$$f: Y_k = P(n, m)_k \longrightarrow P(n)_k \longrightarrow X$$

that induces $f_*\alpha = \alpha$. By Lemma 3.6, $h \circ f: Y_k \rightarrow Y_k$ is a homotopy equivalence. We use the homotopy fibre $j: F \rightarrow X$ of $h$ and the multiplication $\mu$ on $X$ to construct a homotopy equivalence

$$Y_k \times F \xrightarrow{\mu \times j} X \times X \xrightarrow{\mu} X.$$

Then $F$, being a retract of $X$, again satisfies the axioms.

We begin the induction with $Z_0$ as the given space, and find a sequence of equivalences $Z_i \simeq Y_{k_1} \times Z_{i+1}$ for $i \geq 0$. By finiteness, the spaces $Z_i$ become more and more highly connected as $i$ increases, and we deduce $Z_0 \simeq \prod_i Y_{k_i}$ as required. \square

4 $k(n)$-towers with $v_n$-free homotopy

In this section, we prove Theorem 1.6. We must show that the original axiom (iii) of (1.1) is equivalent (in the presence of the other axioms) to axiom (iii)$'$ stated in (1.7), which asserts that $X$ is a $k(n)$-tower with $v_n$-free homotopy. Lemma 4.1 shows that (iii)$'$ implies (iii), while Lemma 4.3 gives the converse.

**Lemma 4.1** Suppose the connected $H$-space $X$ is a $k(n)$-tower of finite type with $v_n$-free homotopy. Then axiom (iii) holds: given $k > 0$, any map $S^k \rightarrow X$ factors through the standard map $u_k: S^k \rightarrow P(n)_k$ to yield a map $P(n)_k \rightarrow X$.

We first show that it does not matter how far up the tower we can lift.

**Lemma 4.2** In diagram (1.4), any map $f: P(n)_k \rightarrow X_{i-1}$ lifts to a map $P(n)_k \rightarrow X$.

**Proof** With $z_i$ as in Definition 1.3, we note that $v_n^*(z_i \circ f) = f^*(v_n^* z_i) = 0$ in $k(n)^*(P(n)_k)$. But by [RW96], $k(n)_* (P(n)_k)$ and hence $k(n)^*(P(n)_k)$ contain no $v_n$-torsion; therefore $z_i \circ f \simeq 0$ and $f$ lifts to $f': P(n)_k \rightarrow X_i$.

By induction and limits, $f$ lifts all the way to $X$. \square

**Proof of Lemma 4.1** For any connected space $Y$ and $k > 0$, let us call an element $\alpha \in \pi_k(Y)$, or map $\alpha: S^k \rightarrow Y$, extendable if it extends over $u_k$ to a map $P(n)_k \rightarrow Y$. 

All elements of $\pi_*(k(n)) \cong \Sigma^qF_p[v_n]$ are obviously extendable. It follows from diagram (1.5) that every element in $\ker[\pi_*(X_i) \to \pi_*(X_{i-1})]$ is extendable.

By Lemma 4.2, any extendable element of $\pi_*(X_{i-1})$ lifts in diagram (1.4) to some extendable element of $\pi_*(X)$.

The sum of any two extendable elements of $\pi_k(X)$ is again extendable: given $f_1, f_2: P(n)_k \to X$, we use the given multiplication $\mu$ on $X$ to construct the map

$$P(n)_k \xrightarrow{\Delta} P(n)_k \times P(n)_k \xrightarrow{f_1 \times f_2} X \times X \xrightarrow{\mu} X.$$

Together, these facts imply that every element of $\pi_*(X)$ is extendable. $\Box$

**The space $Y_k$** A countable product of $k(n)$-towers with $v_n$-free homotopy is another such tower (provided it has finite type). In view of Theorem 1.2(b), it suffices to prove the following.

**Lemma 4.3** For each $k > 0$, the space $Y_k$ is a $k(n)$-tower with $v_n$-free homotopy.

We first destabilize the Johnson–Wilson construction [JW75, §4] of a filtration of the spectrum $P(n)$ whose subquotients are suspensions of $k(n)$, and adapt it for $P(n, m)$. The result will be a tower

$$\ldots \to W_3 \to W_2 \to W_1 \to W_0 = P(n, m)_k$$

(4.4)

with trivial homotopy limit, where each $W_i$ is the homotopy fibre of a map $W_{i-1} \to k(n)_q(i)$ that is epic on homotopy groups. This depends on the following lemma, where we recall that $\pi_* \left( P(n, m)_k \right) \cong \Sigma^k P(n, m)_*$ etc.

**Lemma 4.5** Given $v \in P(n, m)_h$ and $k \leq g(n,m)$, there exist an integer $c$ and stable $P(n)$-operation $r$ such that the composite

$$s: P(n, m)_k \xrightarrow{\theta(m)} P(n)_k \xrightarrow{r} P(n)_{k+h-2cN} \xrightarrow{\rho(n)} k(n)_{k+h-2cN}$$

(4.6)

induces $s_* \Sigma^k v = \Sigma^{k+h-2cN} v_{n}^c$ on homotopy groups.

**Proof** Lemma 1.12 of [JW75], viewed unstably, supplies $c$ and $r$. $\Box$

We construct the tower (4.4) by induction, starting from $W_0 = P(n, m)_k$. Given $j: W_{i-1} \to P(n, m)_k$, where $W_{i-1}$ is $(k+h-1)$-connected and $j_*: \pi_*(W_{i-1}) \to \pi_*(P(n, m)_k)$ is monic, we choose a bottom nonzero element $u \in \pi_{k+h}(W_{i-1})$ to kill. Lemma 4.5 provides a map $s: P(n, m)_k \to k(n)_{k+h-2cN}$ such that $s_*j_*u = \Sigma^{k+h-2cN} v_{n}^c$.

For dimensional reasons, $s \circ j$ factors through $v_{n}^c: P(n, m)_k \to k(n)_{k+h-2cN}$ to produce the desired map $W_{i-1} \to k(n)_{k+h-2cN}$, with fibre $W_i$.

This is the wrong kind of tower for Definition 1.3. To correct it, we could take the homotopy fibre $X_i$ of each map $W_i \to P(n)_k$, to express $\Omega P(n, m)_k = P(n, m)_{k-1}$ as a $k(n)$-tower with $v_n$-free homotopy. This approach fails to produce a suitable tower for $P(n, m)_k$ when $k = g(n, m)$. Our solution is to observe that it is inefficient to deloop and then take fibres; instead, we prove only what we actually need.
LEMMA 4.7 Given a \((k+h)\)-connected map \(q: P(n,m)_k \to X\) and any map \(s: P(n,m)_k \to k(n)_{k+h-2cN}\), there exists a \(v_n\)-torsion map \(z: X \to k(n)_{k+h+1}\) such that \(s\) is one value of the following Toda bracket,

\[
s \in \langle v^c_n, z, q \rangle: P(n,m)_k \to k(n)_{k+h-2cN}.
\]

Proof We are using the adjoint (but equivalent) description of a Toda bracket in terms of loop spaces instead of suspensions. We build the commutative diagram Figure 4.1 in which the two rows are fibration sequences. We start with the obvious fibration as the bottom row, where (stably) \(G\) denotes the cofibre of \(v^c_n: k(n) \to k(n)\), with homotopy \(\mathbb{F}_p[v_n]/(v^c_n)\). By the connectivity of \(q\), \(q^*: G^j(X) \to G^j(P(n,m)_k)\) is an isomorphism for \(j \leq k + h - 2cN + 2N - 1\), so that \(\pi \circ s\) factors uniquely through \(q\) to yield a map \(f\) such that \(f \circ q = \pi \circ s\). We put \(z = \delta \circ f\), which automatically satisfies \(v^c_n z = 0\). We define \(X'\) as the homotopy fibre of \(z\), and fill in \(g\) to form a morphism of fibrations.

Since \(X'\) may be constructed as a pullback, we can fill in \(q'\) to lift \(q\) and satisfy \(g \circ q' = s\). (Equivalently, \(v^c_n \circ [P(n,m)_k, k(n)_{k+h}]\) is part of the indeterminacy of the Toda bracket.) Then by definition, \(g \circ q' = s\) is one value of the Toda bracket. \(\square\)

Proof of Lemma 4.3 We build the desired tower for \(P(n,m)_k\) by induction, starting from a point as \(X_0\). Suppose we have constructed a map \(q_{i-1}: P(n,m)_k \to X_{i-1}\) that induces a surjection \(q_{i-1}: \Sigma^k P(n,m)_s \to \pi_s(X_{i-1})\) on homotopy groups, with kernel \(K\) an \(\mathbb{F}_p[v_n]\)-submodule. We choose a bottom nonzero element \(\Sigma^k v \in K_{k+h}\) to kill, where \(K_i = 0\) for \(i < k + h\). Then Lemma 4.5 provides a map \(s: P(n,m)_k \to k(n)_{k+h-2cN}\). We use Lemma 4.7 to build Figure 4.1, taking \(q_{i-1}\) as \(q\) and \(X_{i-1}\) as \(X\).

We next take homotopy groups of Figure 4.1. By Lemma 3.8(a), applied to \(r \circ \bar{\theta}(m) \circ \rho(m): P(n)_k \to P(n)_{k+h-2cN}\), \(s_*\) is a homomorphism of \(\mathbb{F}_p[v_n]\)-modules. By exactness and the hypothesis that \(q_* \Sigma^k (v^i_n v) = 0\), \(q'_* (v^i_n v)\) must lift to \(-\Sigma^{k+h} v^i_n \in \pi_* (k(n)_{k+h})\). It now follows that \(q'_*\) is also epic, with kernel

\[
K' = \text{Ker} \left[ s_* | K: K \longrightarrow \Sigma^{k+h-2cN} \mathbb{F}_p[v_n]\right] \subset K,
\]

a strictly smaller \(\mathbb{F}_p[v_n]\)-submodule of \(\Sigma^k P(n,m)_s\). We take \(X'\) as \(X_i\) and \(q'\) as \(q_i\).
5 Splittings of $P(n)$-cohomology

In this section, we translate the $H$-space splittings in §3 into splittings of $P(n)$-cohomology. We also deduce Theorems 1.21 and 1.23.

We have yet to prove Lemmas 3.1, 3.6 and 3.8. Lemma 3.1 is equivalent to the following statement for the represented functors. (We do not mention Lemmas 3.6 and 3.8 again until §12.)

**Lemma 5.1** Assume that $k \leq g(n, m)$, where $m \geq n$. Then there is a splitting

$$
\theta(m): P(n, m)^k(X) \to P(n)^k(X)
$$

of $\rho(m): P(n)^k(X) \to P(n, m)^k(X)$ that satisfies $\rho(m) \circ \theta(m) = \text{id}$ and is natural for spaces $X$. It is additive [except when $p = 2$ and $k = g(n, m)$].

This we actually prove in §9 [except the nonadditive case; see [Bo]], by constructing an idempotent cohomology operation $\theta(m)$ in $P(n)^k(X)$. Unlike the case of $BP$, the use of nonadditive operations yields no further splittings [unless $p = 2$].

We next translate equation (3.4).

**Corollary 5.2** For $k \leq g(n, m-1)$, where $m > n$, we have the natural short exact sequence of abelian groups

$$
0 \to P(n, m)^{k+2(p^m-1)}(X) \xrightarrow{\nu_m} P(n, m)^k(X) \xrightarrow{\rho(m-1,m)} P(n, m-1)^k(X) \to 0.
$$

This splits naturally [unless $p = 2$ and $k = g(n, m-1)$].

This implies our homological dimension bound, by the methods of [JW73].

**Proof of Theorem 1.21** Following Yosimura [Yo76, Thm. 4.8], we need to show that

$$
\rho(m-1, m): P(n, m)_i(X) \to P(n, m-1)_i(X)
$$

is epic for all $i$. For $i \leq 2(p^m-1)$, this is trivial, by the exact sequence

$$
P(n, m)_i(X) \xrightarrow{\rho(m-1,m)} P(n, m-1)_i(X) \xrightarrow{\delta} P(n, m)_i-2(p^m-1)-1(X)
$$

arising from the exact triangle (3.2).

For $i > 2(p^m-1)$, we embed $X$ in $\mathbb{R}^{2q+1}$, where $q$ is the dimension of $X$, and take a regular neighborhood $V$ of $X$. By Poincaré duality, (5.3) is equivalent to

$$
\rho(m-1, m): P(n, m)^{2q+1-i}(V, \partial V) \to P(n, m-1)^{2q+1-i}(V, \partial V).
$$

This is epic by Corollary 5.2, because by hypothesis

$$
2q + 1 - i \leq (g(n, m) - 2) + 1 - (2(p^m - 1) + 1) = g(n, m-1).
$$

We also translate Theorem 1.12, using the splittings made explicit in §3, and finally deduce Theorem 1.23. ( Decompositions like (5.6) also follow directly from Corollary 5.2 by induction on $h$, though the resulting homomorphisms are different.)
Theorem 5.4  Let $X$ be any space and suppose that $m \geq n > 0$.

(a) If $k \leq g(n,m)$ [replaced by $k < g(n,m)$ if $p = 2$], we have the natural abelian group decomposition

$$P(n)^k(X) \cong P(n,m)^k(X) \oplus \prod_{j > m} P(n,j)^{k+2(p^j-1)}(X),$$

(5.5)

where the first factor on the right is injected by $\theta(m)$, and the others by

$$P(n,j)^{k+2(p^j-1)}(X) \xrightarrow{\theta(j)} P(n)^{k+2(p^j-1)}(X) \xrightarrow{v_j} P(n)^k(X).$$

Hence, by composition with $\rho(h): P(n)^k(X) \to P(n,h)^k(X)$ for any $h > m$,

$$P(n,h)^k(X) \cong P(n,m)^k(X) \oplus \bigoplus_{j=m+1}^h P(n,j)^{k+2(p^j-1)}(X).$$

(5.6)

These decompositions are maximal if $k > g(n,m-1)$ [also for $k = g(n,m-1)$ if $p = 2$]. (They are in no sense decompositions as $P(n)_*\text{-modules}$.)

(b) If $p = 2$ and $k = g(n,m)$, we replace equations (5.5) and (5.6) by the natural short exact sequences

$$0 \to \prod_{j > m} P(n,j)^{k+2j+1-2}(X) \to P(n)^k(X) \xrightarrow{\rho(m)} P(n,m)^k(X) \to 0$$

and

$$0 \to \bigoplus_{j=m+1}^h P(n,j)^{k+2j+1-2}(X) \to P(n,h)^k(X) \xrightarrow{\rho(m,h)} P(n,m)^k(X) \to 0. \quad \Box$$

Because $P(n,n) = k(n)$ is so familiar, we break out the special case $m = n$. For $h < 2(p^n-1)$, we can even replace $k(n)$ by the periodic Morava $K$-theory $K(n)$.

Corollary 5.7  For $h \leq 2p^n$, where $n > 0$, we have, for all spaces $X$, the natural abelian group decomposition

$$P(n)^h(X) \cong k(n)^h(X) \oplus \prod_{j > n} P(n,j)^{h+2(p^j-1)}(X),$$

except that if $p = 2$ and $h = 2^{n+1}$, we have only the natural short exact sequence

$$0 \to \prod_{j > n} P(n,j)^{h+2j+1-2}(X) \to P(n)^h(X) \xrightarrow{\rho(n)} k(n)^h(X) \to 0. \quad \Box$$

Remark  All the splittings exhibited above depend on the choice of $\theta(m)$, which is not canonical and does not respect multiplication by $v_j$.

Proof of Theorem 1.23  As $X$ is finite-dimensional, the sum in equation (1.22) is essentially finite. Lemma 5.1 shows that $\rho(m)$ is epic. It is clear from Theorem 5.4 that $\text{Ker } \rho(m)$ is contained in the sum, and must therefore be the sum. \quad \Box
6 Stable operations in $P(n)$-cohomology

In this section, we describe the stable operations in $P(n)$-cohomology $P(n)^*(-)$ in the style of [Bo95]. The results are old and well known [except for $p = 2$], but we include them for completeness and ease of reference; more importantly, they serve as a pattern for §§7, 10.

Monoidal structure (For the language of monoidal categories and functors, see e.g. Mac Lane [Ma71, Ch. VII].) Since $P(n)_*$ is a commutative ring [even if $p = 2$], the graded category $(F\text{Mod}_*, \hat{\otimes}, P(n)_*)$ of complete Hausdorff filtered $P(n)_*$-modules is a symmetric monoidal category, with all (completed) tensor products taken over $P(n)_*$. The cross product makes $P(n)$-cohomology a monoidal functor,

$$P(n)^*(-):(\text{Ho}^{op}, \times, \text{point}) \longrightarrow (\text{FMod}_*, \hat{\otimes}, P(n)_*).$$

(Conveniently, $P(n)^*(X)$ has no phantom classes and so is already complete Hausdorff.) For homology, we similarly have the monoidal functor

$$P(n)_*(-):(\text{Ho}, \times, \text{point}) \longrightarrow (\text{Mod}_*, \otimes, P(n)_*),$$

with values in the category $\text{Mod}$ of discrete $P(n)_*$-modules. Both functors are symmetric for $p \neq 2$.

The cohomology version for spectra and graded maps is

$$P(n)^*(-, o):(\text{Stab}^{op}, \wedge, S^0) \longrightarrow (\text{FMod}_*, \hat{\otimes}, P(n)_*),$$

and similarly for homology. (We include the basepoint subspectrum $o$ in our notation as a reminder that all stable (co)homology is reduced, and to distinguish it from the (co)homology of a space, which here will generally be absolute.)

Operations Because $\Gamma = P(n)_*(P(n), o)$ is a free $P(n)_*$-module, we may identify its dual $P(n)_*$-module $D\Gamma$ with $A = P(n)^*(P(n), o)$, the algebra of all stable operations in $P(n)$-cohomology, and have available all the stable machinery and results of [Bo95]. In particular, we have the monoidal functor

$$S:(\text{FMod}_*, \hat{\otimes}, P(n)_*) \longrightarrow (\text{FMod}_*, \hat{\otimes}, P(n)_*)$$

defined by $SM = \text{FMod}_*(A, M)$. If $M$ is filtered by submodules $F^aM$, we filter $SM$ by the submodules $F^aSM = SF^aM$; as in [ibid.], $SM$ is again complete Hausdorff. The ring spectrum structure of $P(n)$ gives $S$ its monoidal structure (see diagram (6.10) below), which is symmetric for $p \neq 2$. (As in [Bo95], care is needed in keeping track of the many $P(n)_*$-module actions, some of which are not obvious.)

The action of stable $P(n)$-cohomology operations is visibly encoded in the monoidal natural transformation

$$\rho_X: P(n)^*(X) \longrightarrow S(P(n)^*(X)) = \text{FMod}_*(P(n)^*(P(n), o), P(n)^*(X))$$

defined by $\rho_X x = x^*$, where we treat $x \in P(n)^*(X)$ as a map of spectra $x:X_+ \rightarrow P(n)$ and $X_+$ denotes the disjoint union of $X$ and a (new) basepoint.

The coaction To convert the action of $\mathcal{A}$ into a coaction by $\Gamma$, we recall the natural isomorphism [Bo95, (11.4)]

$$\theta M:S'M = M \hat{\otimes} \Gamma \cong \text{FMod}_*(D\Gamma, M) \cong \text{FMod}_*(\mathcal{A}, M) = SM,$$
given on \( x \in M, c \in \Gamma, \) and \( r \in A \cong D\Gamma \) by
\[
((\theta M)(x \otimes c))r = \pm \langle r, c \rangle x, \tag{6.5}
\]
with the expected sign. We use it to transfer all the structure from the functor \( S \) to \( S' \) and replace (6.4) by the equivalent natural transformation
\[
\rho_X: P(n)^*(X) \longrightarrow S'P(n)^*(X) = P(n)^*(X) \hat{\otimes} \Gamma. \tag{6.6}
\]

**The monoid** The resulting monoidal structure on \( S' \) is necessarily induced by a monoid structure on the \( P(n)_* \)-module \( \Gamma \) (as we see by naturality from the case \( M = N = P(n)_* \) in diagram (6.10), below), and conversely. We simply need to compute it.

**Lemma 6.7** The following monoid structure on \( \Gamma \), which is inherited from the monoidal functor \( S \), makes the natural transformation (6.6) monoidal:

(a) If \( p \) is odd, the multiplication on \( \Gamma \) is the obvious one,
\[
\Gamma \otimes \Gamma = P(n)_*(P(n)_*o \otimes P(n)_*(P(n)_*o) \xrightarrow{\phi_*} P(n)_*(P(n) \wedge P(n)_*o) \xrightarrow{\phi_*} P(n)_*(P(n)_*o) = \Gamma,
\]
as inferred by writing \( \Gamma = P(n)_*(P(n)_*o) \). The unit homomorphism of \( \Gamma \) is
\[
P(n)_* = P(n)_*(S^0_*, o) \xrightarrow{\eta_*} P(n)_*(P(n)_*o) = \Gamma.
\]

(b) If \( p = 2 \), the multiplication is instead
\[
\Gamma \otimes \Gamma = P(n)_*(P(n)_*o \otimes P(n)_*(P(n)_*o) \xrightarrow{\phi_*} P(n)_*(P(n) \wedge P(n)_*o) \xrightarrow{\phi_*} P(n)_*(P(n)_*o) = \Gamma,
\]
which is better suggested by writing \( \Gamma = \overline{P(n)_*}(P(n)_*o) \). The unit is unaffected.

**Proof** The multiplication \( \phi \) on \( P(n) \) induces
\[
\phi^*: D\Gamma \cong P(n)^*(P(n)_*o) \longrightarrow P(n)^*(P(n) \wedge P(n)_*o) \cong D\Gamma \hat{\otimes} D\Gamma,
\]
with the help of the Künneth formula [Bo95, Thm. 4.19]. The natural transformations \( \zeta(M, N) \) for \( S' \) and \( S \) form the left and right sides of the commutative diagram
\[
\begin{align*}
(M \hat{\otimes} \Gamma) \hat{\otimes} (N \hat{\otimes} \Gamma) & \xrightarrow{\theta M \otimes \theta N} FMod_*(D\Gamma, M) \hat{\otimes} FMod_*(D\Gamma, N) \\
\cong & \xrightarrow{\cong} M \hat{\otimes} N \hat{\otimes} (\Gamma \otimes \Gamma) \\
M \hat{\otimes} N \hat{\otimes} (\Gamma \otimes \Gamma) & \xrightarrow{\theta(M \hat{\otimes} N)} FMod_*(D\Gamma, M \hat{\otimes} N)
\end{align*}
\]
which features the multiplication \( \phi: \Gamma \otimes \Gamma \rightarrow \Gamma \). We evaluate on \( x \otimes c \otimes y \otimes d \), where \( x \in M, y \in N, \) and \( c, d \in \Gamma \). By (6.5), the lower route gives the element \( r \mapsto \)
\(±(r, cd)x \otimes y\) of \(\text{FMod}_s(D\Gamma, M \otimes N)\). The upper route gives \(r \otimes s \mapsto ±(r, c)(s, d)x \otimes y\) in \(\text{FMod}_s(D\Gamma \otimes D\Gamma, M \otimes N)\). Assuming \(p \neq 2\), we can rewrite this as \(±(r \times s, c \times d)x \otimes y\); then in \(\text{FMod}_s(D\Gamma, M \otimes N)\) we find
\[
 r \mapsto ±\langle r^*r, c \times d \rangle x \otimes y = ±\langle r, \phi_*(c \times d) \rangle x \otimes y.
\]
Thus \(cd = \phi_*(c \times d)\) (with no sign) as expected, which is (a).

If \(p = 2\), this calculation is false; we must use equation (2.15) instead, which states that \(\langle r, c \rangle \langle s, d \rangle = \langle r \times s, c \times d \rangle\). Then \(cd = \phi_*(c \times d)\), for (b).

The unit \(z: P(n)_* \to SP(n)_*\) takes \(1 = \eta \in P(n)_*\) to the homomorphism
\[
 D\Gamma \cong P(n)^*(P(n), o) \xrightarrow{\eta^*} P(n)^*(S^0, o) \cong P(n)_*,
\]
in other words, \(r \mapsto \langle \eta^*r, 1 \rangle = \langle r, \eta, 1 \rangle\). Comparison with (6.5) shows that the corresponding element of \(SP(n)_* = P(n)_* \otimes \Gamma \cong \Gamma\) is \(\eta, 1\).

If \(X\) is a point in (6.6), we find the right unit ring homomorphism
\[
 \eta_R: P(n)_* \longrightarrow SP(n)_* = P(n)_* \otimes \Gamma \cong \Gamma,
\]
which is used to make \(\Gamma\) a right \(P(n)_*\)-module (hence a bimodule). Since \(\rho\) is monoidal, this action makes (6.6) a homomorphism of \(P(n)_*\)-modules.

**The Hopf algebroid** Now we add the algebra structure of \(A\). Exactly as in [Bo95, §10], composition of operations and the identity operation induce natural transformations \(\psi: S \to SS\) and \(\epsilon: S \to I\). These make \(S\) a monoidal comonad in the category \(\text{FMod}\), and (6.4) makes \(P(n)^*(X)\) an \(S\)-coalgebra.

We transfer this structure too to \(S'\). The resulting monoidal comonad structure on \(S'\) is necessarily induced by a Hopf algebroid structure on \(\Gamma\) (as we see by taking \(M = P(n)_*\)), and conversely. This structure consists of a coassociative comultiplication \(\psi_S: \Gamma \to \Gamma \otimes \Gamma\) with counit \(\epsilon_S: \Gamma \to P(n)_*\). These behave exactly as in Adams [Ad74] or [Bo95, Thm. 11.35]; in particular, \(\psi_S\) and \(\epsilon_S\) are homomorphisms of \(P(n)_*\)-bimodules and algebras. [This all works without change for \(p = 2\); see [Bo].]

**Proposition 6.12** The stable operations in \(P(n)\)-cohomology are encoded in the Hopf algebroid \(\Gamma = P(n)_*(P(n), o)\) [replaced by \(\Gamma = \overline{P(n)}_*(P(n), o)\) for \(p = 2\)].

The discussion of the structure of \(\Gamma\) carries over from the case \(K(n)\) in [Bo95] with little change [except that we allow \(p = 2\)]. We even use the same test spaces.

**The one-point space** We already discussed this in (6.11). The coaction \(\rho\) reduces to the ring homomorphism \(\eta_R\), which is determined by the elements
\[
w_k = \eta_R v_k \in \Gamma_2(p^k - 1) \quad \text{for } k \geq n.
\]

**Complex orientation** Our next test space is complex projective space \(\mathbb{C}P^\infty\). As \(P(n)\) inherits a complex orientation from \(BP\) (or \(MU\)), we have \(P(n)^*(\mathbb{C}P^\infty) = P(n)_*[[x]]\), the formal power series ring generated by the Chern class \(x = x(\xi)\) of the Hopf line bundle \(\xi\) over \(\mathbb{C}P^\infty\), filtered by powers of the ideal \((x)\).

The coaction \(\rho\) for \(\mathbb{C}P^\infty\) defines elements \(b_j \in \Gamma_{2j-2}\) by the formula [Bo95, (13.2)]
\[
\rho x = b(x) = \sum_{j=1}^\infty x^j \otimes b_j \quad \text{in } P(n)^*(\mathbb{C}P^\infty) \otimes \Gamma \cong \Gamma[[x]].
\]
Here, $b(x)$ is a useful formal abbreviation for the right side. As always in the stable context [ibid., Prop. 13.4], $b_1 = 1$ and $b_0 = 0$.

Further, the comultiplication $\psi_S$ is given on $b_i$ as the coefficient of $x^i$ in

$$\psi_S b(x) = \sum_{j=1}^{\infty} b(x)^j \otimes b_j \quad \text{in} \; (\Gamma \otimes \Gamma)[[x]], \quad (6.15)$$

and $\epsilon_S b_j = 0$ for all $j > 1$.

Since $P(n)$ is $p$-local, we need only the accelerated elements $b_{(j)} = b_{pj} \in \Gamma_{2(p^j - 1)}$ for $j \geq 0$, where $b_{(0)} = 1$; the other $b$'s are expressible in terms of these and the $v$'s and $w$'s by [ibid., Lemma 13.7].

The $p$-th power map $\zeta: \mathbb{C}P^\infty \to \mathbb{C}P^\infty$, whose bundle interpretation is $\zeta^* \xi = \xi^{\otimes p}$, induces in cohomology

$$\zeta^* x = [p](x) = \sum_{i=N}^{\infty} g_i x^{i+1} \quad \text{in} \; P(n)^*([\mathbb{C}P^\infty]) = P(n)_*[[x]]$$

for certain coefficients $g_i \in P(n)_{2i}$. This formal power series is known as the $p$-series for $P(n)$. There are no lower terms as $g_0 = p = 0$ in $P(n)_0$. (The elements $g_i$ are traditionally written $a_i$, but we rename them in order to avoid confusion with other elements, also named $a_i$, that appear shortly.)

We need only one standard fact [RW77, Thm. 3.11(b)] about the $p$-series:

$$[p](x) \equiv v_k x^{p^k} \mod (v_n, \ldots, \hat{v}_k, \ldots) \quad (6.16)$$

for any $k \geq n$, where the ideal is generated by all the $v$’s except $v_k$. In words, $[p](x)$ contains terms $v_k x^{p^k}$ but not $\lambda v_i^k x^\ell$ for any $i > 1$. In particular,

$$[p](x) = v_n x^{p^n} + v_{n+1} x^{p^{n+1}} + \text{higher terms.} \quad (6.17)$$

Hence as $k$ varies, we have

$$[p](x) \equiv \sum_{k=n}^{\infty} v_k x^{p^k} \mod V^2, \quad (6.18)$$

where $V$ denotes the maximal ideal $(v_n, v_{n+1}, v_{n+2}, \ldots) \subset P(n)_*.$

Naturality of $\rho$ with respect to the map $\zeta$ yields the identity [Bo95, (13.11)]

$$b([p](x)) = [p]_\rho (b(x)) = \sum_{i=N}^{\infty} b(x)^{i+1} \eta_R g_i \quad \text{in} \; \Gamma[[x]]. \quad (6.19)$$

The lowest power of $x$ that occurs is $x^{p^n}$.

**Definition 6.20** For each $k \geq n$, we define the $k$-th main stable relation $(\mathcal{R}_k)$ as the coefficient of $x^{p^k}$ in equation (6.19).

Since $b_{(0)} = 1$, the first relation $(\mathcal{R}_n)$ is simply $v_n 1 = w_n$, which implies that every stable operation is $v_n$-linear. For $k > n$, equation (6.18) shows that (6.19) has a term $w_k x^{p^k}$ on the right, and $(\mathcal{R}_k)$ becomes an inductive formula for $w_k$ in terms of the $v$’s and $b$’s and lower $w$’s.
Cohomology of a lens space, for \( p \) odd  
Our final test space is the \( 2N \)-skeleton \( L \) of the lens space \( K(\mathbb{Z}/p, 1) \). Geometrically, \( L \) is the orbit space of the standard \( \mathbb{Z}/p \)-action on the unit sphere \( S^{2N+1} \subset \mathbb{C}^{N+1} \) given as complex multiplication by \( \mathbb{Z}/p \subset S^1 \subset \mathbb{C} \), with the top cell omitted by requiring the last coordinate to be real non-negative, up to the action of \( \mathbb{Z}/p \). (Retaining the top cell, as in [Bo95], adds some extra complication but offers little benefit.)

Following [Bo95, §14], its cohomology is
\[
P(n)^*(L) = \left( E(u) \otimes TP_n(x) \right)/\langle ux^N \rangle,
\]
(6.21)
because the Atiyah–Hirzebruch spectral sequence can support no differential. Here, \( x \) is induced from the Chern class of the Hopf line bundle on \( \mathbb{CP}^N \), which is a quotient space of \( L \), and \( u \) is uniquely defined as restricting to the standard generator \( u_1 \in P(n)^*(S^1) \), where we recognize the 1-skeleton \( L_1 \) of \( L \) as the circle \( S^1 \).

Since \( x \) is a Chern class, the coaction \( \rho_L \) is given on \( x \) by naturality as
\[
\rho_L x = b(x).
\]
Although \( L \) is not an \( H \)-space, there are, as in [ibid., (14.31)], partial multiplications \( L^{2k} \times L^{2m} \rightarrow L \) on the skeletons whenever \( k + m = N \), which imply that
\[
\rho_L u = u \otimes 1 + \sum_{i=0}^{n-1} x^{p^i} \otimes a(i) \quad \text{in } P(n)^*(L) \otimes \Gamma
\]
(6.22)
for certain elements \( a(i) \in \Gamma_{2p^i-1} \) that this equation defines. (We warn that these generators differ from Würgler’s [Wü77] and Yagita’s [Ya77] generators \( a_i \) by the conjugation in \( \Gamma \); as a result, certain formulae become transposed. Our generators are chosen for compatibility with [Bo95] and [Wi84], because they destabilize properly in §§7, 10.) The element \( a(n) \) does not exist because \( u \) fails to lift to the \( 2p^n \)-skeleton of the lens space. As in [Bo95, Thm. 14.32], the coalgebra structure is given by
\[
\psi_S a(k) = a(k) \otimes 1 + \sum_{i=0}^{k-1} t^{p^i} \otimes a(i) + 1 \otimes a(k)
\]
(6.23)
and \( \epsilon_S a(k) = 0 \).

Cohomology of real projective space, for \( p = 2 \)  
Here, the same test space \( L \) is better known as real projective space \( \mathbb{RP}^{2N} \). It remains true that the Atiyah–Hirzebruch spectral sequence can support no differential, so that
\[
P(n)^*(\mathbb{RP}^{2N}) = P(n)[t]/(t^{2N+1}),
\]
(6.24)
generated by the unique nonzero element \( t \in P(n)[1](\mathbb{RP}^{2N}) \). As above, we find that
\[
\rho t = t \otimes 1 + \sum_{i=0}^{n-1} t^{2^i+1} \otimes a(i),
\]
(6.25)
which defines elements \( a(i) \in \Gamma_{2^i+1-1} \). Indeed, this formula is identical to equation (6.22), since \( x = t^2 \) is the Chern class of the complexified real Hopf line bundle. Thus equation (6.23) remains valid for \( p = 2 \).

Summary  
Würgler [Wü77] and Yagita [Ya77] both proved that we now have enough elements of \( \Gamma \) to handle all stable operations.
Theorem 6.26  The stable operations in \( P(n) \)-cohomology are dual to the Hopf algebroid \( \Gamma = P(n)_s(P(n), o) \) [replaced by \( \overline{P(n)}_s(P(n), o) \) if \( p = 2 \)], which is generated as a \( P(n)_s \)-algebra by the elements \( b_{(j)} \) and \( a_{(i)} \) defined by equations (6.14) and (6.22) [replaced by (6.25) if \( p = 2 \)].

(a) For odd \( p \), as a \( P(n)_s \)-algebra,
\[
\Gamma = P(n)_s(P(n), o) = E(a(0), a(1), \ldots, a(n-1)) \otimes P(b(1), b(2), b(3), \ldots);
\]
(b) For \( p = 2 \), as a \( P(n)_s \)-algebra,
\[
\Gamma = \overline{P(n)}_s(P(n), o) = P(a(0), a(1), \ldots, a(n-1), b(n+1), b(n+2), \ldots);
\]

and the elements \( b_{(j)} \) for \( j \leq n \) are given by the relations
\[
a^{2}_{(j)} = b_{(j+1)} \quad \text{for} \quad 0 \leq i \leq n - 1; \quad (6.27)
\]

(c) As a left \( P(n)_s \)-module, \( \Gamma \) is free with a basis consisting of all monomials
\[
a^I b^J = a_{(0)}^{i_0} a_{(1)}^{i_1} \cdots a_{(n-1)}^{i_{n-1}} b_{(1)}^{j_1} b_{(2)}^{j_2} b_{(3)}^{j_3} \cdots,
\]

with multi-indices \( I = (i_0, i_1, \ldots, i_{n-1}) \) and \( J = (j_1, j_2, \ldots) \) in which each \( i_r = 0 \) or 1;

(d) The right \( P(n)_s \)-action on \( \Gamma \) is given by multiplication by the elements \( w_k = \eta_{Rv_k} \), where \( w_n = v_n \) and \( w_k \) is determined inductively for \( k > n \) by the main relation (6.20);

(e) The counit \( \epsilon_S; \Gamma \to \Gamma \otimes \Gamma \) is the \( P(n)_s \)-algebra homomorphism given on the generators by equations (6.15) and (6.23);

(f) The counit \( \epsilon_S; \Gamma \to P(n)_s \) is the \( P(n)_s \)-algebra homomorphism given on the generators by \( \epsilon_S a_{(i)} = 0 \) for all \( i \) and \( \epsilon_S b_{(j)} = 0 \) for \( j > 0 \).

Proof  What survives intact from Würgler [Wü77, Thm. 2.13] and Yagita [Ya77, Lemma 3.5], even for \( p = 2 \), is (c) (using the conjugate generators to the \( a_{(i)} \)). Parts (a), (d), (e) and (f) need no further comment.

[In (b), commutativity is not trivial; see Nassau [Na02] or [Bo]. Since \( t^2 \) is a Chern class, \( (\rho t)^2 = \rho(t^2) = b(t^2) \). Comparing the coefficients of \( t^{2i+2} \) with the help of (6.14) and (6.25), we deduce (6.27) for \( i < n-1 \). This argument fails for \( i = n-1 \), as \( t^{2n+1} = 0 \); nevertheless, the result still holds by [Na02, Thm. 2], which corrects [KW87]. Alternatively, the map of ring spectra \( P(n) \to P(n+1) \) in Lemma 2.7 sends each generator of \( \Gamma(n) = \Gamma \) to its namesake in \( \Gamma(n+1) \). As \( a_{n-1}^2 = b(n) \) in \( \Gamma(n+1) \), the only candidates for \( a_{n-1}^2 \) in \( \Gamma(n) \) are \( b(n) \) and \( b(n) + v_n 1 \). Since \( \epsilon_S (a_{n-1}^2) = (\epsilon_S a_{n-1})^2 = 0 \), we must choose \( b(n) \).]

\[ \Box \]

7  Additive operations in \( P(n) \)-cohomology

In this section, we describe the additive unstable operations in \( P(n) \)-cohomology in the style of [BJW95], in terms of a certain bigraded algebra \( Q_\ast \), which, like \( \Gamma \), is a \( P(n)_s \)-bimodule equipped with a coalgebra structure \( (\psi_A, \epsilon_A) \) (called \( (Q(\psi), Q(\epsilon)) \)) in [BJW95] that encodes the composition of operations and the identity operation. Although the results bear a strong formal resemblance to the stable results in §6, the stable proofs do not carry over; instead, one has to compute the whole Hopf ring in §11 and then take the indecomposables.
For $p$ odd, we define $Q^*_r = QP(n)_*(P(n)_k)$, the algebra of indecomposables in the Hopf ring $P(n)_*(P(n)_k)$. Specifically, $Q^*_i$ denotes the group of indecomposables in degree $i$ of the Hopf algebra $P(n)_*(P(n)_k)$; its elements have total degree $i - k$ in $Q^*_r$ (and this is the degree that governs signs). The multiplication and unit in $Q^*_r$ are induced from $\circ$-multiplication and the element $[1]$ in the Hopf ring by the homomorphisms (10.1). The left $P(n)_*$-module action is induced from the Hopf ring: if $v \in P(n)_j$ and $c \in Q^*_k$, we have $vc \in Q^*_j$. When $p = 2$, it should be no surprise after Proposition 6.12 that the correct Hopf ring to consider is not $P(n)_*(P(n)_k)$ but $P(n)_*_1(P(n)_k)$; in this case, we set $Q^*_r = Q\overline{P(n)}_*(P(n)_k)$. This is the same left $P(n)_*$-module as $QP(n)_*(P(n)_k)$, but with slightly different multiplication.

By [RW96, Cor. 1.5], both $Q^*_r$ and the Hopf ring are free $P(n)_*$-modules. These conditions ensure [BJW95, Lemma 4.16(a)] that the dual module to $Q^*_r$ is indeed the module of all additive unstable operations on $P(n)_*$-cohomology, and make available all the machinery and results on additive operations. We thus identify:

(i) The additive unstable operation $r: P(n)^k(-) \to P(n)^m(-)$;
(ii) The primitive cohomology class $r_k \in P(n)^m_*(\overline{P(n)}_k)$;
(iii) The representing $H$-map of $H$-spaces $r: \overline{P(n)}_k \to \overline{P(n)}_m$, up to homotopy;
(iv) The $P(n)_*$-linear functional $\langle r, - \rangle: Q^*_k \to P(n)_*$, of degree $k - m$.

The action of additive operations on $P(n)^*(X)$ is encoded in coactions

$$\rho_X: P(n)^k(X) \to P(n)^*(X) \otimes Q^*_k$$

(one for each $k$), which are monoidal as $k$ varies [even if $p = 2$].

To construct the generators of $Q^*_r$, we use the same test spaces as stably in §56, together with the circle. We record the values of $\psi_A$ and $\epsilon_A$ on each generator.

**Cohomology of a point** The right unit ring homomorphism $\eta_R: P(n)_* \to Q^*_r$ is just the coaction $\rho$ for the one-point space, and so is determined by the elements

$$w_k = \eta_Rv_k \in Q_0^{-2(2^k - 1)} \quad \text{for } k \geq n.$$  
(7.2)

We use $\eta_R$ to make $Q^*_r$ a right $P(n)_*$-module and the coactions $\rho_X$ in (7.1) into a $P(n)_*$-module homomorphism.

**Cohomology of a circle** The coaction for the circle $S^1$ defines the suspension element $e \in Q^*_1$ by

$$\rho u_1 = u_1 \otimes e \quad \text{in } P(n)^*(S^1) \otimes Q^*_1 = E(u_1) \otimes Q^*_1.$$  
(7.3)

As in [BJW95, Prop. 12.3(d)], $\psi_A e = e \otimes e$ and $\epsilon_A e = 1$.

Then for any $j > 0$, the coaction for the $j$-sphere $S^j$ is given by

$$\rho u_j = u_j \otimes e^j \quad \text{in } P(n)^*(S^j) \otimes Q^*_j = E(u_j) \otimes Q^*_j.$$  
(7.4)

Given any additive operation $r: P(n)^k(-) \to P(n)^m(-)$, represented by the map $r: \overline{P(n)}_k \to \overline{P(n)}_m$, where $k, m > 0$, we use $P(n)^k(S^j) \cong \pi_j(\overline{P(n)}_k) \cong \Sigma^k P(n)_{j-k}$ to...
By equation (6.18), the general main relation for $k$ is

$$r_*: \Sigma^k P(n)_* \cong \pi_* \left( P(n)_k \right) \xrightarrow{\pi_*(i)} \pi_* \left( P(n)_m \right) \cong \Sigma^m P(n)_*. \quad (7.5)$$

By [BJW95, Cor. 12.4], this is given on $\Sigma^k v$, where $v \in P(n)_i$, by the formula

$$r_*(\Sigma^k v) = \Sigma^m \langle r, e^{k+i}(nRv) \rangle. \quad (7.6)$$

Complex orientation

The coaction for $\mathbb{C}P^\infty$ defines elements $b_j \in Q_2^2$ by

$$\rho x = b(x) = \sum_{j=1}^{\infty} x^j \otimes b_j \quad \text{in} \quad P(n)^* (\mathbb{C}P^\infty) \otimes Q_2^2 \cong Q_2^2 \langle x \rangle, \quad (7.7)$$

which is formally identical to equation (6.14), except that now $b_1 = e^2$ by [BJW95, Prop. 14.4(a)]. As in [ibid.], $\psi_A b_i$ is the coefficient of $x^i$ in

$$\psi_A b_i(x) = \sum_{j=1}^{\infty} b(x)^j \otimes b_j \quad \text{in} \quad (Q_i^* \otimes Q_2^2) \langle x \rangle, \quad (7.8)$$

and $\epsilon_A b_j = 0$ for $j > 1$.

Again [ibid., Lemma 14.6], we need only the accelerated elements $b(j) = b_{pj}$ for $j \geq 0$, so $b(0) = e^2$. The additive version of equation (6.19) also looks the same,

$$b([p](x)) = [p] R(b(x)) = \sum_{i=N}^{\infty} b(x)^{i+1} \eta_R g_i \quad \text{in} \quad Q_2^1 \langle x \rangle. \quad (7.9)$$

**Definition 7.10** For each $k \geq n$, we define the $k$-th main additive relation $(\mathcal{R}_k)$ as the coefficient of $x^{p^k}$ in equation (7.9).

In view of equation (6.17), the first two main relations are simply

$$(\mathcal{R}_n) \quad b_{(0)}^{p^n} w_n = v_n b_{(0)} \quad \text{in} \quad Q_2^1 \quad (7.11)$$

and

$$(\mathcal{R}_{n+1}) \quad b_{(1)}^{p^n} w_n + b_{(0)}^{p^{n+1}} w_{n+1} = v_{n+1} b_{(0)} + v_p^n b_{(1)} \quad \text{in} \quad Q_2^2. \quad (7.12)$$

We shall find in equation (10.10) that $(\mathcal{R}_n)$ desuspends once to

$$(\mathcal{R}_n') \quad e b_{(0)}^n w_n = v_n e \quad \text{in} \quad Q_1^1. \quad (7.13)$$

By equation (6.18), the general main relation for $k \geq n$ has the form

$$(\mathcal{R}_k) \quad \sum_{i=0}^{k} b_{(k-i)}^{p^i} w_i \equiv 0 \quad \text{in} \quad Q_2^1 \mod \mathfrak{W} + \mathfrak{W}^2, \quad (7.14)$$

where $\mathfrak{W} = (v_n, v_{n+1}, v_{n+2}, \ldots)$ and $\mathfrak{W} = (w_n, w_{n+1}, w_{n+2}, \ldots)$ denote ideals in $Q_2^1$.

**Cohomology of a lens space** Our last test space is the lens space skeleton $L$, whose cohomology is given by equation (6.21), assuming $p$ is odd. We already know $\rho_L x = b(x)$ from equation (7.7). For $u$, we find, as in [BJW95, (16.21)], that

$$\rho_L u = u \otimes e + \sum_{i=0}^{n-1} x^{p^i} \otimes a_{(i)} \quad \text{in} \quad P(n)^* (L) \otimes Q_2^1 \quad (7.15)$$
for certain elements $a_{(i)} \in Q^1_{2p^i}$ that this equation defines. We deduce that

$$\psi_A a_{(k)} = a_{(k)} \otimes e + \sum_{i=0}^{k} b_{(k-i)}^p \otimes a_{(i)} \tag{7.16}$$

and $\epsilon_A a_{(k)} = 0$. 

If $p = 2$, $L = \mathbb{R}P^{2N}$ has different cohomology (6.24), and we replace equation (7.15) by

$$\rho t = t \otimes e + \sum_{i=0}^{n-1} t^{2i+1} \otimes a_{(i)} \quad \text{in } P(t)/(t^{2N+1}) \otimes Q^1_* \tag{7.17}$$

Nevertheless, equation (7.16) and $\epsilon_A a_{(k)} = 0$ remain valid for $p = 2$. By [Bo], equation (6.27) destabilizes in the obvious way, to

$$a_{(i)}^2 = b_{(i+1)} \quad \text{for } 0 \leq i \leq n - 1. \tag{7.18}$$

**More relations**  We shall find in equation (10.14) that one more suspension factor can be squeezed out of (7.13) if we first multiply by $a_{(0)}$, to give

$$(\mathcal{R}^n_0) a_{(0)}b_{(0)}^n w_n = v_n a_{(0)} \quad \text{in } Q^1_* \tag{7.19}$$

[When $p = 2$, we can multiply this by another $a_{(0)}$ and use equation (7.18) to obtain the unexpected formula

$$b_{(0)}^n b_{(1)} w_n = v_n b_{(1)} \tag{7.20}$$

This is not all; if we multiply $(\mathcal{R}_{n+1}) (7.12)$ by $b_{(0)}^n$, we obtain the reduction formula

$$b_{(0)}^{n+2^n+1} w_{n+1} = v_n^2 b_{(0)}^n b_{(1)} + v_n b_{(1)} + v_{n+1} b_{(0)}^{2^n} \tag{7.21}$$

by using (7.20) to simplify one of the terms.]

**Summary**  We have the additive version of the Hopf algebroid $\Gamma$.

**Theorem 7.22**  The additive unstable operations in $P(n)_*$-cohomology are dual to the $P(n)_*$-algebra $Q_* = QP(n)_* \left( P(n)_* \right)$ [replaced by $QP(n)_* \left( P(n)_* \right)$ if $p = 2$], which has the properties:

(a) $Q_*^*$ is the commutative bigraded $P(n)_*$-algebra generated by the elements:

$$w_k \in Q^1_{2p^k-1} \quad \text{for } k \geq n, \text{ defined by } \eta_R \text{ in equation (7.2)};$$

$$e \in Q^1_1, \text{ the suspension element, defined by equation (7.3)};$$

$$b_{(j)} \in Q^2_{2p^j} \quad \text{for } j \geq 0, \text{ defined by equation (7.7)};$$

$$a_{(i)} \in Q^1_{2p^i} \quad \text{for } 0 \leq i < n, \text{ defined by (7.15) [replaced by (7.17) if } p = 2];}$$

subject to the relations $e^2 = b_{(0)}$, the main relations $(\mathcal{R}_k)$ for $k > n$ (see Definition 7.10), and the two variants (7.13) and (7.19) of $(\mathcal{R}_n)$ [also (7.18) if $p = 2$];

(b) $Q_*^*$ is a free left $P(n)_*$-module;

(c) Multiplication by the elements $w_k$ makes $Q_*^*$ a right $P(n)_*$-module;

(d) The comultiplication $\psi_A: Q_*^* \to Q_*^* \otimes Q_*^*$ is the homomorphism of algebras and of $P(n)_*$-bimodules given on each generator as noted above;

(e) The counit $\epsilon_A: Q_*^* \to P(n)_*$ is the $P(n)_*$-algebra homomorphism given on generators by $\epsilon_A e = 1$, $\epsilon_A a_{(i)} = 0$, $\epsilon_A b_{(j)} = 0$ for $j > 0$, $\epsilon_A b_{(0)} = 1$, and $\epsilon_A w_k = v_k$.\]
Parts (c), (d) and (e) need no further comment. Part (a) can be read off from Theorem 11.1. [For commutativity when \(p = 2\), we refer to [Bo].]

We recall [BJW95, (6.3)] the stabilization homomorphism \(Q(\sigma): Q_*^\infty \to \Gamma\), which has degree zero. We may use it to recover the structure on \(\Gamma\) in Theorem 6.26 from \(Q_*^\infty\) simply by setting \(e = 1\). The coalgebra structure \((\psi_A, \epsilon_A)\) stabilizes to \((\psi_S, \epsilon_S)\).

8 Relations for additive operations

We noted in Theorem 7.22 that \(Q_*^\infty\) is a free \(P(n)_*\)-module, which is not at all obvious from the generators and relations given. In this section, we exhibit a basis of \(Q_*^\infty\) and prove in Lemma 8.5 that it spans the module.

We also establish some direct applications of additive operations.

The Ravenel–Wilson basis Since \(e^2 = b_{(0)}\) and \(a_{(i)}^2 = 0\) trivially if \(p\) is odd [replaced by \(a_{(i)}^2 = b_{(i+1)}\) if \(p = 2\), from equation (7.18)], any monomial in the listed generators of the \(P(n)_*\)-algebra \(Q_*^\infty\) can be written in the abbreviated form

\[
e^i a_i^j b^j w^K = e^i a_{(i)}^{i_0} a_{(1)}^{i_1} \ldots a_{(n-1)}^{i_{n-1}} b_{(0)}^{d_0} b_{(1)}^{d_1} b_{(2)}^{d_2} \ldots b_n^{d_n} w_{n+1}^{k_{n+1}} w_{n+2}^{k_{n+2}} \ldots,
\]

with multi-indices \(I = (i_0, i_1, \ldots, i_{n-1}), J = (j_0, j_1, j_2, \ldots), K = (k_n, k_{n+1}, \ldots),\) where each \(i_r, j_r,\) also \(\epsilon_r\), is 0 or 1. (We keep the \(w\)'s to the right, as a reminder that they define the right action of \(P(n)_*\) on \(Q_*^\infty\).) We introduce the following parameters:

The \(b\)-length is \(\sum_i j_r\), the total number of factors of the form \(b_{(j)}\);

The \(w\)-length is \(\sum_i k_r\), the total number of factors of the form \(w_k\).

As with \(BP\) in [RW77], it is easier to specify which monomials are not wanted in forming the basis than those which are. [For \(p = 2\), the basis is not written out in detail in [RW96], and contains some surprises.] There are two variants; we shall need the second in §§10, 11.

Definition 8.2 We call the monomial (8.1) \(Q\)-allowable if it does not have any of the following forms [note that (iv) and (v) apply only if \(p = 2\)]:

\[
\begin{align*}
(i) \quad b_{(d_n)}^{p_d} b_{(d_n+1)}^{p_{d_n+1}} \ldots b_{(d_q)}^{p_d} w_q c, & \quad \text{with } 0 \leq d_n \leq d_{n+1} \leq \ldots \leq d_q, \ q \geq n; \\
(ii) \quad e b_{(0)}^{p_0} b_{(d_{n+1})}^{p_{n+1}} \ldots b_{(d_q)}^{p_d} w_q c, & \quad \text{with } 0 \leq d_{n+1} \leq \ldots \leq d_q, \ q \geq n; \\
(iii) \quad a_{(0)} b_{(0)}^{p_0} b_{(d_{n+1})}^{p_{n+1}} \ldots b_{(d_q)}^{p_d} w_q c, & \quad \text{with } 0 \leq d_{n+1} \leq \ldots \leq d_q, \ q \geq n; \\
(iv) \quad b_{(0)}^{N_0} b_{(d_{n+1})}^{N_{n+1}} \ldots b_{(d_q)}^{N_d} w_q c, & \quad \text{where } p = 2, \ 0 \leq d_{n+1} \leq \ldots \leq d_q, \ q \geq n; \\
(v) \quad b_{(0)}^{N_0+2n+1} b_{(d_{n+2})}^{2n+2} \ldots b_{(d_q)}^{p_d} w_q c, & \quad \text{where } p = 2, \ 0 \leq d_{n+2} \leq \ldots \leq d_q, \ q \geq n + 1;
\end{align*}
\]

where \(c\) is any monomial (\(c = 1\) is permitted) in the generators \(e, a_{(i)}, b_{(j)},\) and \(w_k\).

More generally, we call the monomial allowable if it is not of the form (i) or (ii).
Remark In [RW96], a monomial is called $n$-allowable (lies in $\mathcal{A}_n$) if it is not of the form (i). If it contains a factor $e$ or $a_{(0)}$, it is called $n$-plus allowable (lies in $\mathcal{A}_n^+$) if it is not of the form (i), (ii) or (iii).

From [RW96, Thm. 1.3], we have the Ravenel–Wilson basis of $Q_*^n$.

**Theorem 8.4 (Ravenel–Wilson)** The $Q$-allowable monomials (8.1) form a basis of the free $P(n)_*$-module $Q_*^n = QP(n)_*\left(\prod_{i \geq 0} P(n)_i\right)$ if $p \neq 2$.

Later in this section, we shall reprove half the theorem.

**Lemma 8.5** The relations $e^2 = b_{(0)}$, the main relations $(R_k)$ for $k > n$, [relation (7.18) if $p = 2$,] and the variants (7.13) and (7.19) of $(R_n)$ imply that the $Q$-allowable monomials (8.1) span the $P(n)_*$-module $Q_*^n = QP(n)_*\left(\prod_{i \geq 0} P(n)_i\right)$ if $p = 2$.

**Generators of cohomology** Just as in [BJW95, Thm. 20.2], Theorem 1.16 follows directly from the fact that the additive operations on $P(n)^{-k}(-)$ form the $P(n)_*$-dual of the free $P(n)_*$-module $Q_*^{-k}$, whose generators all lie in groups $Q_{j-k}$ with $j \geq 0$.

We combine the following two lemmas, which correspond to Theorem 20.3 and Lemma 20.5 of [ibid.]. We study the linear functional $\epsilon_A = \langle \iota_{-k}, - \rangle: Q_*^{-k} \to P(n)_*$ defined by the identity operation $\iota$ on $P(n)^{-k}(-)$, which is plainly additive.

**Lemma 8.6** Given any integer $k > 0$, there exist:

(i) a sequence of additive unstable operations $r_i: P(n)^{-k}(-) \to P(n)^{m(i)}(-)$ with $m(i) \geq 0$;

(ii) a sequence of elements $v(i) \in P(n)_*$ with $\deg(v(i)) \to -\infty$;

such that in any additively unstable $P(n)$-cohomology comodule $M$ (e.g. $P(n)^*(X)$ for any space $X$), any $x \in M^{-k}$ decomposes as the (topological infinite) sum

$$x = \sum_i v(i)r_ix.$$  

**Proof** Let $\{c_1, c_2, c_3, \ldots\}$ be the Ravenel–Wilson (or any other) basis of the free $P(n)_*$-module $Q_*^{-k}$, with $c_i \in Q_*^{-m(i)}$. Trivially, $m(i) \geq 0$. For fixed $x \in M^{-k}$ and any additive operation $r$, the linearity of $rx$ in $r$ may be expressed, as in [BJW95, (6.39)], by the formula

$$rx = \sum_i \langle r, c_i \rangle r_ix,$$  

where $r_i$ denotes the operation dual to $c_i$. We take $r = \iota_{-k}$, put $v(i) = \langle \iota_{-k}, c_i \rangle$, and note that $\deg(v(i)) = m(i) + k \to -\infty$. □

**Remark** The coefficients are readily computed: $v(i) = \epsilon_A c_i = v^K$ if the monomial $c_i$ has the form $e^kb_{(0)}w^K$, and $v(i) = 0$ otherwise. Thus many terms are zero.

To get the more precise information for Theorem 1.16, we write the space $X$ as the disjoint union of its components and reduce to the case when $X$ is connected.
Lemma 8.8 Let $M$ be a connected (see [BJW95, Defn. 7.14]) additively unstable $P(n)$-cohomology algebra (e.g. $P(n)^*(X)$ for any connected space $X$). Then as a topological $P(n)_*$-module, $M$ is generated by $1_M \in M^0$ and elements of $M^i$ for $i > 0$. The generator $1_M$ is never redundant.

Proof Let $L$ be the submodule generated (topologically) by the elements of all the $M^i$ for $i > 0$. By Lemma 8.6, we need only consider $x \in M^0$. We choose a basis \{c_1, c_2, c_3, \ldots \} of $Q^0$ with $c_1 = 1$.

We recall from [BJW95, Defn. 7.13] the collapse operation $\kappa_j$ on $P(n)^j(-)$ for any $j$; since $M$ is connected, on any $x \in M^j$ it satisfies $\kappa_j x = v_1^M$ for some $v \in P(n)_{-j}$. But (8.7) gives $\kappa_0 x \equiv r_1 x \mod L$ and also $x = t_0 x \equiv r_1 x \mod L$. Thus $x \equiv \kappa_0 x = \lambda_1^M \mod L$ for some $\lambda \in \mathbb{F}_p$.

Since $\kappa L = 0$ and $\kappa_0 1_M = 1_M$, $1_M$ never lies in $L$. □

Higher-order relations The proof of Lemma 8.5 resembles that of [BJW95, Thm. 18.16]. The Nakayama Lemma [Bo95, §15] (which is easier for $P(n)_*$ than for $BP_*$, as $p = 0$) allows us to work throughout modulo the ideal $\mathfrak{W} \subset Q^*$. We also work modulo powers of $\mathfrak{W}$. (These ideals were introduced in equation (7.14), which displays the $w$-linear terms in the relation $(\mathcal{R}_k)$.)

When $q = n$ and $c = 1$, we observe that (8.3)(i) is the first term in $(\mathcal{R}_{dn+n})$, and is thus expressible by equation (7.14) in terms of $Q$-allowable monomials mod $\mathfrak{W} + 2\mathfrak{W}^2$. Equation (7.13) shows that $(\mathcal{R}_k')$ takes care of (ii), while (7.19) shows that $(\mathcal{R}_k')$ takes care of (iii). [If $p = 2$, we use (7.20) and (7.21) to handle (iv) and (v).]

Otherwise, the relations $(\mathcal{R}_k)$ are not at all transparent. We handle the general disallowed monomial (8.3)(i) by eliminating the $q - n$ variables $w_n, w_{n+1}, \ldots, w_{q-1}$ from the $q - n + 1$ relations $(\mathcal{R}_{dn+n}), (\mathcal{R}_{dn+n+1}), \ldots, (\mathcal{R}_{dn+q})$, expressed in the form (7.14), to obtain the higher-order derived relation

$$\Delta_q w_q + \sum_{r > q} \Delta_r w_r \equiv 0 \mod \mathfrak{W} + 2\mathfrak{W}^2,$$

for certain determinants $\Delta_r$. Explicitly, for any $r \geq q$,

$$\Delta_r = \sum_\pi \epsilon_\pi b_{(dn+n-\pi n)}^{\pi} \cdots b_{(d_{q-1}+q-1-\pi(q-1))}^{(q-1)} b_{(d_q+q-\pi r)}^{\pi r},$$

where we sum over all permutations $\pi$ of \{n, \ldots, q-1, r\}, write $\epsilon_\pi$ for the sign of $\pi$, and adopt the convention that meaningless factors $b_{(j)}$ with $j < 0$ are taken as 0.

We order the $b$-monomials lexicographically $b^j < b^k$ if and only if there exists $t \geq 0$ such that $j_r = k_r$ for all $r \leq t$, and $j_t < k_t$.

Lemma 8.11 For any $r \geq q$, the determinant $\Delta_r$ in (8.10) has the form

$$\Delta_r = b_{(dn)}^{\pi n} b_{(dn+1)}^{\pi n+1} \cdots b_{(d_{q-1})}^{\pi q-1} b_{(d_q+q-r)}^{\pi r} + \text{higher terms},$$

Proof The displayed term is the diagonal term with $\pi = \text{id}$. For any other permutation $\pi$, there is a first index $t$ such that $\pi t > t$, so that $n \leq t \leq q - 1$ and $\pi k = k$ for all $k < t$. The corresponding term $\epsilon_\pi b_{(dn)}^{\pi n} \cdots b_{(d_{q-1})}^{\pi q-1} b_{(d_t+t-\pi t)}^{\pi t} \cdots$ in (8.10) is higher, because $d_t + t - \pi t < d_t$. □
Proof of Lemma 8.5  We show that each \( Q \)-disallowed monomial in (8.3) is a linear combination mod \( \mathfrak{V} \) of higher monomials with the same \( w \)-length, and monomials of greater \( w \)-length, where we partially order all monomials according to the factor \( b^j \) (and ignore \( e, a_{(i)}, \) and \( w_k \)). Since there are only finitely many monomials in each bidegree, the result follows.

For (8.3)(i), Lemma 8.11 shows that we can use (8.9) to express \( b_{(da)}^\rho \cdots b_{(da)}^\rho w_q \) as a linear combination mod \( \mathfrak{V} \) of higher monomials and monomials with \( w \)-length \( \geq 2 \), since for \( r > q \), the diagonal term of \( \Delta_r \) is higher than the diagonal term of \( \Delta_q \). Multiplication by \( c \) preserves the ordering.

For (ii), (iii) [and (iv), if \( p = 2 \)], we modify equation (8.9) by eliminating the variables \( w_{n+1}, \ldots, w_{q-1} \) from the relations \( (R_{dn+1+n+1}), \ldots, (R_{dn+q}) \) to obtain

\[
\Delta'_n w_n + \Delta'_q w_q + \sum_{r>q} \Delta'_r w_r \equiv 0 \mod \mathfrak{V} + \mathfrak{W}^2.
\]

When we multiply by \( eb_n^Nc \), the first term drops out by (7.13). Lemma 8.11, slightly modified (or with \( n \) replaced by \( n + 1 \)), shows that (ii) is the lowest of the remaining terms. If we multiply by \( a_{(0)}b_n^Nc \) instead and use (7.19), we obtain (iii). [For (iv), we multiply by \( b_{(1)}^N b_{(1)}c \) and use (7.20).]

[For (v), we eliminate the variables \( w_{n+2}, \ldots, w_{q-1} \) from the relations \( (R_{dn+2+n+2}), \ldots, (R_{dn+q}) \) to obtain a higher-order relation]

\[
\Delta''_n w_n + \Delta''_{n+1} w_{n+1} + \Delta''_q w_q + \sum_{r>q} \Delta''_r w_r \equiv 0 \mod \mathfrak{V} + \mathfrak{W}^2.
\]

When we multiply this by \( b^{N+2n+1}_{(0)} c \), the first two terms drop out by (7.11) and (7.21). The diagonal term in the determinant \( \Delta'_n \) gives (v). \( \Box \)

The first higher-order relation  The first relation for a given \( q \), where we eliminate \( w_n, w_{n+1}, \ldots, w_{q-1} \) from \( (R_n), (R_{n+1}), \ldots, (R_q) \), is particularly important. The additive version for \( P(n) \) of Bendersky’s Lemma [Be86, Thm. 6.2] (or see [BJW95, Lemma 18.23]) gives more precise information than our proof of Lemma 8.5, and follows immediately from Lemma 12.2.

We recall the ideal \( I_q = (v_n, v_{n+1}, \ldots, v_{q-1}) \subset P(n)_* \) (where \( I_n = (0) \)).

**Lemma 8.12**  In \( Q^* = QP(n)_* \left( P(n)_* \right) \) [replaced by \( QP(n)_* \left( P(n)_* \right) \) if \( p = 2 \)], we have the relation

\[
e^{g(n,n)-1} w_q \equiv v_q e^{g(n,q-1)+1} \mod I_q Q^* \quad \text{for } q \geq n. \tag{8.13}
\]

[If \( p = 2 \), this is almost superseded by the relation]

\[
e^{g(n,q)-2} w_q \equiv v_q e^{g(n,q-1)} \mod I_q Q^* \quad \text{for } q \geq n + 1. \tag{8.14}
\]

**Primitive elements**  Let \( M \) be an unstable \( P(n) \)-cohomology comodule (in the sense of [BJW95, Defn. 6.32]). An element \( x \in M^k \) is called (additively unstably) primitive if the coaction \( \rho_M \) has the value \( \rho_M x = x \otimes e^k \) on \( x \). Then for any \( v \in P(n)_* \),

\[
\rho_M(vx) = x \otimes e^k(\eta v). \tag{8.15}
\]

Of course, all this requires \( k \geq 0 \), but more is true, as in [ibid., Lemma 20.8].
Lemma 8.16 Let $x \in M^k$ be a nonzero primitive element of the unstable $P(n)$-cohomology comodule $M$, and assume $q \geq n$.

(a) If $I_q x = 0$ and $k$ satisfies the condition (depending on $p$ and $q$):

(i) $k \geq g(n, q) - 1$ if $p$ is odd or $q = n$;

(ii) $k \geq g(n, q) - 2$ if $p = 2$ and $q \geq n + 1$;

then $v_q x$ is primitive (possibly zero);

(b) If $k$ does not satisfy the condition (8.17), then for all $i > 0$, $v_q^i x$ is nonzero and is not primitive.

Proof For (a), (8.15) gives $\rho(v_q^i x) = x \otimes e^k w_q$. By Lemma 8.12, this is the same as $x \otimes v_q e^{k-2(p^q-1)} = v_q x \otimes e^{k-2(p^q-1)}$, since $I_q x = 0$.

For (b), we have $\rho(v_q^i x) = x \otimes e^{k w_q}$. Here, $e^{k w_q}$ is $Q$-allowable by (8.3) and hence a basis element of $Q^*$, which shows that $v_q^i x$ is not primitive. □

Proof of Lemma 1.17 We must have $\rho x = x \otimes e^k$. If $m > n$, we have $v_{m-1} x = 0$, and case (b) of Lemma 8.16 with $q = m - 1$ does not apply; hence the lower bound on $k$.

Conversely, (8.15) specifies the coaction on all of $M$, and Lemma 8.12 shows it is well defined. □

Proof of Theorem 1.18 We build an increasing sequence

$$0 = M_0 \subset M_1 \subset M_2 \subset \ldots \subset M$$

of subcomodules of $M$. For each $i > 0$, just as in the proof of Theorem 20.11 in [BJW95], we construct a primitive element $x_i \in M/M_{i-1}$ with $\text{Ann}(x_i) = I_{m_i}$ for some $m_i$, using Lemma 8.16 in place of Lemma 20.8 of [ibid.]. We take $M_i/M_{i-1} \subset M/M_{i-1}$ as the $P(n)_*$-submodule generated by $x_i$. Lemma 1.17 describes $M_i/M_{i-1}$.

Because each $k_i \geq 0$ in Theorem 1.18 and each $M^k$ is a finitely generated $\mathbb{F}_p$-module, this sequence must terminate after finitely many steps. We deduce that $M$ is a finitely presented $P(n)_*$-module. □

9 Idempotent operations

Lemma 9.1 delivers the promised additive idempotent operations $\theta(m)$ in $P(n)$-cohomology that we need for Lemma 5.1, which is equivalent to Lemma 3.1. In fact, we find a large class of $\theta(m)$, among which none seems to be preferred. The rest of this section applies the work in §8 to prove Lemma 9.1.

Lemma 9.1 Assume that $k \leq g(n, m)$ [replaced by $k \leq g(n, m) - 1$ if $p = 2$], where $m \geq n$. Then there exists an additive idempotent operation $\theta(m)$ on $P(n)^k(-)$ having the following properties:

(i) The image of the operation $\theta(m)$ is represented by the space $P(n, m)_k$;

(ii) The map $\theta(m): P(n)^k \to P(n)^k$ factors to yield an H-space splitting $\overline{\theta(m)}: P(n, m)_k \to P(n)^k$ of the canonical $H$-map $\rho(m): P(n)_k \to P(n, m)_k$;

(iii) For all spaces $X$, $\overline{\theta(m)}$ naturally embeds $P(n, m)^*(X) \subset P(n)^*(X)$ as a summand, in the sense of abelian groups (but not as $P(n)_*$-modules).
Remark. Exactly as in [BJW95, end of §22], we can make the splittings \( \theta(m) \) compatible as \( k \) and \( m \) vary if we wish. The decomposition factors of \( P(n) \) resulting from this approach must of course be the same as in Theorem 1.12, according to Theorem 1.2(b), but the injection maps are different, in general.

However, we emphasize that the splitting theorems as stated in §§1, 5 do not require any compatibility.

The ideals \( \mathfrak{J}_m \). As in [BJW95], the ideal \( J_m = (v_{m+1}, v_{m+2}, \ldots) \subset P(n)_* \), introduced in equation (1.8), gives rise to an analogous ideal for the right action of \( P(n)_* \) on \( Q_*^t \).

Definition 9.2. Given any \( m \geq n \), we define the ideal

\[
\mathfrak{J}_m = (w_{m+1}, w_{m+2}, w_{m+3}, \ldots) \subset Q_*^t.
\]

We need to know how \( \mathfrak{J}_m \) sits inside \( Q_*^t \). As in [ibid.], the answer is remarkably clean, in a certain range.

Lemma 9.3. For \( k \leq g(n, m) \) [replaced by \( k \leq g(n, m) - 1 \) if \( p = 2 \)], \( Q_*^t \cap \mathfrak{J}_m \) is the left \( P(n)_* \)-submodule of \( Q_*^t \) spanned by all the \( Q \)-allowable monomials (8.1) that lie in it and contain an explicit factor \( w_q \) for some \( q > m \).

Remark. By Lemma 8.12, \( v_{m+1}eb_{(0)}^{(n,m)/2} - z \) lies in \( \mathfrak{J}_m \), where \( z \in I_{m+1}Q_*^t \), so the result definitely fails for \( k = g(n, m) + 1 \) [also for \( k = g(n, m) \) if \( p = 2 \)].

Proof. Any monomial that contains \( w_h \) with \( h > m \) visibly lies in \( \mathfrak{J}_m \). To show the converse, we fix \( k \) and \( i_0 \) and prove by downward induction on \( h \) that for all \( i \leq i_0 \), all elements in \( Q_*^t \) of the form \( cw_h \) lie in the indicated \( P(n)_* \)-submodule. This statement is trivial for sufficiently large \( h \) (depending on \( k \) and \( i_0 \)).

We therefore choose \( q > m \), assume the statement holds for all \( h > q \), and prove it for \( h = q \). Take \( cw_q \in Q_*^t \), where \( i \leq i_0 \), so that \( c \in Q_{i+2}^{k+2(\nu-1)} \). By Lemma 8.5, we may reduce to the case where \( c \) is a \( Q \)-allowable monomial. We note that in (8.3), the \( Q \)-disallowed monomials (i) and (iv) have \( b \)-length \( \frac{1}{2}g(n, q) \), while (ii), (iii) and (v) have \( b \)-length \( \frac{1}{2}g(n, q) - 1 \).

Case 1: \( c \) has no factor \( e, a_{(0)} \), or \( w_j \). For odd \( p \), the \( b \)-length of \( c \) is at most

\[
\frac{1}{2}(k + 2(p\nu - 1)) \leq \frac{1}{2}(g(n, m) + 2p\nu - 2) < \frac{1}{2}g(n, q),
\]

which makes \( cw_q \) also \( Q \)-allowable, as only rule (i) of (8.3) is relevant. [If \( p = 2 \), we need to assume \( k \leq g(n, m) - 1 \) to get the stronger bound \( \frac{1}{2}g(n, q) - 1 \).]

Case 2: \( c = ey \) or \( c = a_{(0)}y \), where \( y \) has no factor \( w_j \). In this case, the \( b \)-length of \( c \) is at most

\[
\frac{1}{2}(k - 1 + 2(p\nu - 1)) \leq \frac{1}{2}(g(n, m) + 2p\nu - 3) < \frac{1}{2}g(n, q) - 1,
\]

which makes \( cw_q \) automatically \( Q \)-allowable.

Case 3: \( c = yw_j \), where \( j \leq q \). Then \( cw_q \) remains \( Q \)-allowable, by the form of Definition 8.2.

Case 4: \( c = yw_j \), where \( j > q \). By induction, \( cw_q = (yw_q)w_j \) lies in the indicated submodule. □

Linear functionals. To establish Lemma 9.1, we actually construct the associated \( P(n)_* \)-linear functional \( \langle \theta(m), - \rangle : Q_*^t \rightarrow P(n)_* \).
Lemma 9.4 Assume the linear functional $\langle \theta(m), - \rangle: Q^n_k \rightarrow P(n)_*$ corresponding to the additive operation $\theta(m): P(n)^k(-) \rightarrow P(n)^k(-)$ satisfies the conditions:

\begin{equation}
\begin{align*}
(i) \quad & \langle \theta(m), Q^n_k \cap J_m \rangle = 0; \\
(ii) \quad & \langle \theta(m), c \rangle \equiv \epsilon_A c \mod J_m \quad \text{for all } c \in Q^n_k;
\end{align*}
\end{equation}

where $\epsilon_A: Q^n_k \rightarrow P(n)_*$ is the augmentation. Then:

(a) The homology homomorphism $Q(\theta(m)_*): Q^n_k \rightarrow Q^n_k$ induced by the representing map $\theta(m): P(n)_k \rightarrow P(n)_k$ satisfies

\begin{equation}
\begin{align*}
(i) \quad & Q(\theta(m)_*)(Q^n_k \cap J_m) = 0; \\
(ii) \quad & Q(\theta(m)_*) \equiv \text{id}: Q^n_k \rightarrow Q^n_k \mod J_m;
\end{align*}
\end{equation}

(b) $Q(\theta(m)_*)$ induces a splitting of the short exact sequence

$$0 \rightarrow Q^n_k \cap J_m \rightarrow Q^n_k \rightarrow Q^n_k/(Q^n_k \cap J_m) \rightarrow 0$$

of left $P(n)_*$-modules;

(c) The operation $\theta(m)$ is idempotent and has the properties listed in Lemma 9.1.

Proof The proof is patterned after that of Lemma 22.2 in [BJW95]. We require the commutative diagram

\[
\begin{array}{cccccc}
Q^n_k & \xrightarrow{\psi_A} & Q^n_k \otimes Q^n_k & \xrightarrow{\text{id} \otimes (\theta(m)_*)} & Q^n_k \otimes P(n)_* & \xrightarrow{\lambda_R} & Q^n_* \\
\downarrow q' & & \downarrow & & \downarrow & & \downarrow q' \\
\overline{Q^n_k} \oplus \overline{J_m} & \xrightarrow{\overline{\psi}_A} & \overline{Q^n_k} \otimes \overline{Q^n_k} \oplus \overline{J_m} & \xrightarrow{\text{id} \otimes \overline{\theta}} & \overline{Q^n_k} \otimes \overline{P(n)_*} / \overline{J_m} & \xrightarrow{\overline{\lambda_R}} & \overline{Q^n_*} \\
& & & & & & \\
\end{array}
\]

of $P(n)_*$-module homomorphisms, where $\overline{\psi}_A$, $\overline{\epsilon}_A$ and $\overline{\lambda}_R$ denote quotients of $\psi_A$, $\epsilon_A$, and the right action $\lambda_R$ of $P(n)_*$ on $Q^n_k$, $\overline{Q^n_k} \oplus \overline{J_m}$ is really $Q^n_k/(Q^n_k \cap J_m)$, and the vertical arrows are the obvious projections. The conditions (9.5) on $\langle \theta(m), - \rangle$ are exactly what we need to fill in the diagonal.

By [BJW95, Lemma 6.51(c)], the top row gives the homology homomorphism $Q(\theta(m)_*)$, while by [ibid., (6.31)], the bottom row reduces to the identity homomorphism of $\overline{Q^n_k} \oplus \overline{J_m}$. Thus the diagonal provides a splitting we call $q': \overline{Q^n_k} \oplus \overline{J_m} \rightarrow Q^n_k$ that satisfies $q' \circ q = Q(\theta(m)_*)$ and $q' \circ q' = \text{id}$ and so yields (a). Part (b) is merely a restatement of (a).

It follows by faithfulness that $\theta(m)$ is an idempotent operation, so that the image $h(-) = \theta(m)P(n)^k(-) \subset P(n)^k(-)$ is an ungraded cohomology theory. By [Bo95, Thm. 3.6], $h(-)$ is represented (on $H\text{-}\text{mod}$) by some $H$-space $Y$, and the additive operations $h(-) \subset P(n)^k(-)$ and $\theta(m): P(n)^k(-) \rightarrow h(-)$ are represented by $H$-maps $j: Y \rightarrow P(n)_k$ and $q: P(n)_k \rightarrow Y$ respectively, that satisfy $j \circ q = \theta(m)$ and $q \circ j = \text{id}$.

To finish (c), we apply the homotopy group functor $\pi_*(-)$ to obtain homomorphisms $q_*: \pi_*\bigl(\overline{P(n)_k}\bigr) \rightarrow \pi_*\bigl(\overline{Y}\bigr)$ and $j_*: \pi_*\bigl(\overline{Y}\bigr) \rightarrow \pi_*\bigl(\overline{P(n)_k}\bigr)$ that satisfy $q_* \circ j_* = \text{id}$ and $j_* \circ q_* = \theta(m)_*$. Recall that $\pi_*\bigl(\overline{P(n)_k}\bigr) \cong \Sigma^k P(n)_*$. Given $v \in P(n)_i$, (7.6)
evaluates $\theta(m) \Sigma^k v = \Sigma^k \langle \theta(m), e^{k+i}(\eta_R v) \rangle$. Then (9.5)(i) yields $\theta(m) \Sigma^k v = 0$ if $v \in J_m$, while for any $v$, (ii) gives $\theta(m) \Sigma^k v \equiv \Sigma^k v \mod J_m$. It follows that $\rho(m) \circ j: Y \to P(n,m)_k$ induces an isomorphism of homotopy groups and is therefore a homotopy equivalence. To establish the properties listed in Lemma 9.1, we put $\bar{\theta}(m) = j \circ g$, where $g: P(n,m)_k \to Y$ is a homotopy inverse to $\rho(m) \circ j$. 

Proof of Lemma 9.1  Lemma 9.3 makes it obvious that linear functionals $\langle \theta(m), - \rangle$ exist that satisfy the conditions (9.5), so that Lemma 9.4 applies. 

Remark  As an explicit example, choose $\langle \theta(m), - \rangle$ on the Ravenel–Wilson basis as $\langle \theta(m), c \rangle = v^K$ if $c$ has the form $e^p b_{(q)} w^K$ but contains no factor $w_k$ with $k > m$, and $\langle \theta(m), c \rangle = 0$ otherwise. To determine $\langle \theta(m), c \rangle$ for $c$ not in the basis, we must first express $c$ in terms of the basis.

10 Unstable operations in $P(n)$-cohomology

In this section, we use all unstable operations in $P(n)$-cohomology to obtain generators and relations for the Hopf ring $P(n)_*(P(n)_*)$, in the style of [BJW95]. The two multiplications are $c_+ d = \mu_*(c \times d)$ and $c_+ d = \phi_*(c \times d)$, induced respectively by the maps $\mu: P(n)_k \times P(n)_k \to P(n)_k$ and $\phi: P(n)_k \times P(n)_m \to P(n)_{k+m}$ that represent addition and multiplication in $P(n)$-cohomology, and $1_k$ will denote the $*$-identity element of $P(n)_*(P(n)_*)$. [If $p = 2$, we use the Hopf ring $P(n)_*(P(n)_*)$ instead, replacing $c \times d$ by $\overline{c \times d}$ in both multiplications.] We still assume that $0 < n < \infty$.

We deduce the results of §7 on additive operations by applying the homomorphism

$$q_k: P(n)_*(P(n)_*) \longrightarrow Q^k_*,$$  

(10.1)

which neglects $1_k$ and decomposables, shifts degrees by $-k$, and (as $k$ varies) takes $*$-products to products (with a sign, on account of the degree shift). However, the Hopf ring structure maps $\psi$ and $\epsilon$ are unrelated to $\psi_A$ and $\epsilon_A$.

Since the Hopf ring is a free $P(n)_*$-module by [RW96, Cor. 1.5], Theorem 4.14 of [BJW95] allows us to identify:

(i) The cohomology operation $r: P(n)^k(-) \to P(n)^m(-)$;

(ii) The cohomology class $r_*(\nu_k) \in P(n)_m(P(n)_k)$;

(iii) The representing map of spaces $r: P(n)_k \to P(n)_m$, up to homotopy;

(iv) The $P(n)_*$-linear functional $\langle r, - \rangle: P(n)_*(P(n)_k) \to P(n)_*$ of degree $-m$ [or $\langle r, - \rangle: \overline{P(n)}_*(P(n)_k) \to P(n)_*$ if $p = 2$].

Hopf rings for $p = 2$  When $p = 2$, $P(n)_*(P(n)_*)$ and $\overline{P(n)}_*(P(n)_*)$ are not Hopf rings in the ordinary sense (though $H_*(P(n)_*; F_2)$ is one, and is described in [BW01] and after Theorem 11.8). (A few things are simpler: there are no signs and $\chi$ is the identity.) Because $P(n)$ is not commutative, all Hopf ring axioms that shuffle factors must be modified to use the commutativity isomorphism $T_Q$ of equation (2.11), which results in extra terms; see §2 or [Bo] for details. Neither multiplication is commutative in the ordinary sense, nor is $\psi$ cocommutative.
As a $P(n)_*$-module, the Hopf ring $\overline{P(n)}_*(P(n)_*)$ is identical to $P(n)_*(P(n)_*)$. The choice of multiplication on $P(n)$ does not affect the $P(n)_*$-module structure on $\overline{P(n)}_*(P(n)_*)$, nor does it affect the $\circ$-generators that we construct below. However, switching to the other good multiplication on $P(n)$ replaces $c \circ d = \phi_*(c \overline{x} d)$ by 
\[\tilde{\phi}_*(c \times d) = \phi_*(c \overline{x} d) = \phi_*(d \overline{x} c) = d \circ c,\]
which is different in general; and similarly for $c \ast d$.

**The Cartan formulae** Assume first that $p$ is odd. Given a cohomology class $x \in P(n)^k(X)$, we encode the action of operations on $x$ by a formula of the form
\[r(x) = \sum_{\alpha} \langle r, c_\alpha \rangle x_\alpha \quad \text{for all } r,\]
for suitable choices $c_\alpha \in P(n)_*(P(n)_*)$ and $x_\alpha \in P(n)^*(X)$. (Here and elsewhere, we mean all operations $r$ that have the correct domain degree. The sum may be infinite if $X$ is not finite-dimensional.) Similarly, given $y \in P(n)^m(X)$, suppose
\[r(y) = \sum_{\beta} \langle r, d_\beta \rangle y_\beta \quad \text{for all } r.
\]
Then the two Cartan formulae [BJW95, (10.23) and (10.36)] are:
\[r(x + y) = \sum_{\alpha} \sum_{\beta} (-1)^{\deg(x_\alpha) \deg(y_\beta)} \langle r, c_\alpha \ast d_\beta \rangle x_\alpha y_\beta \quad \text{(10.2)}\]
and
\[r(xy) = \sum_{\alpha} \sum_{\beta} (-1)^{\deg(x_\alpha) \deg(y_\beta)} \langle r, c_\alpha \circ d_\beta \rangle x_\alpha y_\beta. \quad \text{(10.3)}\]
We use them repeatedly without further reference.

**The case $p = 2$** Examination reveals that the proof of the Cartan formulae in [BJW95] relies on the identity $\langle x \times y, a \times b \rangle = \pm \langle x, a \rangle \langle y, b \rangle$, which is false for $p = 2$; we must replace $a \times b$ by $a \overline{x} b$ and use equation (2.15) instead. When we use the Hopf ring $\overline{P(n)}_*(P(n)_*)$, both Cartan formulae remain valid as stated.

**Cohomology of a point** Our first test space is the one-point space. For each $v \in P(n)_q$, the Hopf ring element $[v] \in P(n)_0(\overline{P(n)}_{-q})$ [or $\overline{P(n)}_0(P(n)_{-q})$ if $p = 2$] is defined by the identity
\[r(v) = \langle r, [v] \rangle \quad \text{in } P(n)^*(\text{point}) = P(n)_*, \text{ for all } r. \quad \text{(10.4)}\]
The properties of these elements were listed in [BJW95, Prop. 11.2]. As $[v + v'] = [v] \ast [v']$ and $[vv'] = [v] \circ [v']$, we are primarily interested in the elements
\[[v_k] \in P(n)_0(\overline{P(n)}_{-2(p^k - 1)}) \quad \text{for } k \geq n\]
[or in $\overline{P(n)}_0(P(n)_{-2(2^k - 1)})$ if $p = 2$]. Then (10.1) maps $[v_k]$ to $w_k$.

We have the important relation
\[1]^p = [p] = [0] = 1_0. \quad \text{(10.5)}\]
Cohomology of a circle  Our second test space is the circle $S^1$. The suspension element $e = e_1 \in P(n)_1 \left(P(n)_1 \right)$ or $P(n)_1 \left(P(n)_1 \right)$ if $p = 2$ is defined by the action of operations $r$ on the standard generator $u_1 \in P(n)_1(S^1)$,

$$r(u_1) = \langle r, 1 \rangle_{1} 1_{S} + \langle r, e \rangle u_1 \quad \text{in} \quad P(n)^*(S^1) = E(u_1), \text{for all} \quad r.$$  

(10.6)

The properties of $e$ were listed in [BJW95, Prop. 13.7].

Complex orientation  Our third test space is $\mathbb{C}P^\infty$. The Hopf ring elements $b_j \in P(n)_{2j} \left(\mathbb{P}(n)_2 \right)$ or $P(n)_{2j} \left(\mathbb{P}(n)_2 \right)$ if $p = 2$ for $j \geq 0$ are defined by the identity

$$r(x) = \langle r, b_j \rangle = \sum_{j=0}^{\infty} \langle r, b_j \rangle x^j \quad \text{in} \quad P(n)^*(\mathbb{C}P^\infty) \cong P(n)*[x], \text{for all} \quad r,$$

(10.7)

where $b(x)$ is a convenient formal abbreviation for $\sum_j b_j x^j$. Their properties were listed in [BJW95, Prop. 15.3]. In particular, $b_0 = 1_2$ is now nonzero and $b_1 = -e \circ e$. Again, the accelerated elements $b_{(j)} = b_{\rho} \in P(n)_{2\rho} \left(\mathbb{P}(n)_2 \right)$ or $P(n)_{2\rho} \left(\mathbb{P}(n)_2 \right)$ if $p = 2$ suffice, as [ibid., Lemma 15.9] shows how to express the other $b$'s inductively in terms of these and the $v$'s and $[v]$'s.

Naturality of equation (10.7) with respect to the $p$-th power map $\zeta: \mathbb{C}P^\infty \to \mathbb{C}P^\infty$, with massive use of the Cartan formulæ, yields the identity

$$b([p](x)) = \prod_{i=N}^{\infty} \{b(x)^{e_{i+1}}(g_i)\} \quad \text{in} \quad P(n)_* \left(\mathbb{P}(n)_2 \right)[[x]]$$

(10.8)

[or in $P(n)_* \left(\mathbb{P}(n)_2 \right)[[x]]$ if $p = 2$], as in [ibid., (15.14)]. The lowest power of $x$ that occurs is still $x^{e_2}$, apart from the term $1_2$ on each side.

DEFINITION 10.9  For each $k \geq n$, we define the $k$-th main unstable relation $(R_k)$ as the coefficient of $x^{e_2}$ in equation (10.8).

The first relation is simply

$$(R_n) \quad v_n b_{(0)} = b_{(0)} \circ v_n \quad \text{in} \quad P(n)_* \left(\mathbb{P}(n)_2 \right)$$

[or in $P(n)_* \left(\mathbb{P}(n)_2 \right)$ if $p = 2$]. By [RW96, Prop. 2.1(j)], it desuspends once to

$$(R_n') \quad v_n e = e \circ b_{(0)}^N \circ v_n \quad \text{in} \quad P(n)_* \left(\mathbb{P}(n)_1 \right)$$

(10.10)

[or in $P(n)_* \left(\mathbb{P}(n)_1 \right)$ if $p = 2$]. The second relation is almost as easy, in view of equation (6.17):

$$(R_{n+1}) \quad b_{(1)}^{e_2} \circ v_n \ast b_{(0)}^{e_2} \ast v_{n+1} = v_n b_{(1)} + v_{n+1} b_{(0)}.$$ 

(10.11)

Cohomology of a lens space, for $p$ odd  Our final test space is the lens space skeleton $L$, whose cohomology (6.21) has two generators $u$ and $x$. As $x$ is a Chern class, equation (10.7) gives $r(x)$ by naturality. We define Hopf ring elements $a_i$ and $c_i$ by the identity

$$r(u) = \sum_{i=0}^{N} \langle r, a_i \rangle x^i + \sum_{i=0}^{N-1} \langle r, c_i \rangle u x^i \quad \text{in} \quad P(n)^*(L), \text{for all} \quad r.$$ 

(10.12)
Not by coincidence, their formal properties are exactly the same as in the case \( E = K(n) \) of [BJW95]. The formal abbreviation \( a(x) = \sum_i a_i x^i \) is convenient.

**Proposition 10.13** For \( p \) odd, the Hopf ring elements \( a_i \in P(n)_{2i}(P(n)_{p}) \) (for \( 0 \leq i < p^n \)), \( a_{(i)} = a_{p^i} \in P(n)_{2p^i}(P(n)_{p}) \) (for \( 0 \leq i < n \)), and \( c_i \in P(n)_{2i+1}(P(n)_{1}) \) (for \( 0 \leq i \leq p^n - 2 \)) defined by equation (10.12) have the following properties:

(a) \( a_0 = 1 \) and \( c_0 = e \);
(b) \( \psi a_k = \sum_{i+j=k} a_i \otimes a_j \);
(c) \( e a_i = 0 \) for all \( i > 0 \), in particular, \( e a_{(i)} = 0 \) for all \( i \);
(d) \( a_i \ast a_j = \binom{i+j}{i} a_{i+j} \), provided \( i + j < p^n \);
(e) \( a_{p^i} = 0 \) for \( 0 \leq i < n - 1 \);
(f) \( \chi a_i = (-1)^i a_i \), in particular, \( \chi a_{(i)} = -a_{(i)} \);
(g) \( c_i = e \ast a_i \);
(h) \( a_{(i)} \circ a_{(j)} = -a_{(j)} \circ a_{(i)} \);
(i) \( a_{(i)} \circ a_{(i)} = 0 \);
(j) For all \( r, r \ast a_k \) is the coefficient of \( x^k \) in the formal identity

\[
 r \ast a(x) = \sum_{i=0}^{N} \{ b(x)^{\circ i} \circ [(r, a_i)] \} \ast \sum_{i=0}^{N-1} \{ a(x) \circ b(x)^{\circ i} \circ [(r, c_i)] \}
\]

in \( P(n)_{*}(P(n)_{*})[x]/(x^{2n}) \).

**Proof** The statement and proof are identical to [BJW95, Prop. 17.16], except that we offer a simpler proof of (f) (and could have also in [ibid.]; compare the divided power Hopf algebra \( \Gamma(a_{(i)}) \)).

If \( m \) is odd, say \( m = 2k + 1 \), we can write the defining equation for \( \chi a_m \) as

\[
 \chi a_m + \sum_{i=1}^{k} (\chi a_{m-i} \ast a_i + \chi a_i \ast a_{m-i}) + a_m = 0.
\]

By induction, the terms in the sum cancel in pairs, as \( m-i \) and \( i \) have opposite parity.

If \( m \) is even, (d) decomposes \( a_m \) as a \( \ast \)-product, and we again use induction. \( \square \)

We emphasize that (e) is not valid for \( i = n - 1 \); instead, [RW96, Prop. 2.1(i)] shows that the unstable analogue of equation (7.19) is

\[
 (R_n^p) \quad a_{p^{n-1}}^{(i)} = v_n a_{(0)} - a_{(0)} \circ b_{(i)}^{N} \circ [v_n] \quad \text{in} \ P(n)_{*}(P(n)_{1}).
\]  

**Cohomology of real projective space, for \( p = 2 \)** In this case, \( L = \mathbb{R}P^{2N} \), with cohomology (6.24). We define Hopf ring elements \( f_i \) by the identity

\[
 r(t) = \sum_{i=0}^{2N} \langle r, f_i \rangle t^i \quad \text{in} \ P(n)^* (\mathbb{R}P^{2N}) = P(n)*[t]/(t^{2N+1}), \quad \text{for all} \ r.
\]  

Again, we mimic equation (10.12) by writing \( a_i = f_{2i}, \ a_{(i)} = a_{2i} = f_{2i+1}, \) and \( c_i = f_{2i+1} \). We make the obvious changes to Proposition 10.13 and write \( f(t) = \sum t f_i t^i \).
We warn that the analogy is not perfect; \( \psi a_k \) acquires many extra terms. Also, (d) now requires proof; see [Bo].

**Proposition 10.16** For \( p = 2 \), the Hopf ring elements \( f_i \in \overline{P(n)}_*(\overline{P(n)}_*) \) (for \( 0 \leq i \leq 2N \)) and \( a(i) = f_{2i+1} \in \overline{P(n)}_{2i+1}*(\overline{P(n)}_*) \) (for \( 0 \leq i \leq n-1 \)) defined by equation (10.15) have the following properties:

(a) \( f_0 = 1 \) and \( f_1 = e \);  
(b) \( \psi f_k = \sum_{i+j=k} f_i \otimes f_j \);  
(c) \( \epsilon f_i = 0 \) for all \( i > 0 \), in particular, \( \epsilon a(i) = 0 \) for all \( i \);  
(d) \( a(i) \circ a(j) = a(j) \circ a(i) \);  
(e) \( f_i \circ f_j = \binom{i+j}{i} f_{i+j} \), provided \( i+j \leq 2N \);  
(f) \( a(i) \circ a(i) = 0 \) for \( 0 \leq i < n-1 \);  
(g) For all \( r, r_* f_k \) is the coefficient of \( t^k \) in the formal identity

\[
r_* f(t) = \sum_{i=0}^{2N} \{ f(t)^{i} \circ \{ r, f_i \} \} \quad \text{in} \quad \overline{P(n)}_*(\overline{P(n)}_*)[t]/(t^{2N+1}). \]

Again, for \( i = n-1 \), (f) is replaced by (10.14), now taken in \( \overline{P(n)}_*(\overline{P(n)}_*) \).
Finally, we prove in [Bo] that equation (7.18) lifts in the obvious way.

**Lemma 10.17** In the Hopf ring \( \overline{P(n)}_*(\overline{P(n)}_*) \) for \( p = 2 \), we have

\[
a(i) \circ a(i) = b(i+1) \quad \text{for} \quad 0 \leq i \leq n-1.
\]  

**Remark** There is a case for writing \( e \) here as \( a(-1) \), so that the identity \( e \circ e = b(0) \) becomes a natural extension of (10.18).

## 11 Structure of the Hopf ring

In this section, we present two descriptions of the Hopf ring \( P(n)_*(\overline{P(n)}_*) \) [replaced by \( \overline{P(n)}_*(\overline{P(n)}_*) \) if \( p = 2 \): a clean concise description in terms of the generators and relations developed in §10, and a concrete computational description that specifies exactly what the elements of the Hopf ring are. (This relies heavily on the technical work of Ravenel–Wilson [RW96], and in no way replaces it.)

**Theorem 11.1** (Ravenel–Wilson) The Hopf ring \( P(n)_*(\overline{P(n)}_*) \) [which is replaced by \( \overline{P(n)}_*(\overline{P(n)}_*) \) if \( p = 2 \)] over \( P(n)_* \) has the \( \circ \)-generators:

\[
[v_k] \in P(n)_0(\overline{P(n)}_{2(p^k-1)}) \quad \text{for} \quad k \geq n, \quad \text{defined by equation (10.4)}; 
\]
\[
e \in P(n)_1(\overline{P(n)}_1), \quad \text{defined by equation (10.6)}; 
\]
\[
b(j) = b_{pj} \in P(n)_{2pj}(\overline{P(n)}_2) \quad \text{for} \quad j \geq 0, \quad \text{defined by equation (10.7)}; 
\]
\[
a(i) = a_{pi} \in P(n)_{2pi}(\overline{P(n)}_1) \quad \text{for} \quad 0 \leq i < n, \quad \text{defined by equation (10.12)} \quad \text{[replaced by (10.15) if \( p = 2 \)]};
\]
subject to the relations \([1]^p = 1_0, e \cdot e = -b_{(0)}\), the main relations \((R_k)\) for \(k > n\) (see Definition 10.9), and the two variants \((10.10)\) and \((10.14)\) of \((R_n)\) [also \((10.18)\) if \(p = 2\)].

### Allowable monomials

For our second description of the Hopf ring, we reinterpret the general monomial \((8.1)\) as the \(o\)-monomial

\[
e^{o} a^{l_1} b^{o} j_0 [v^k] = e^{o} a^{l_1} a^{(0)}(1) a^{(1)}(0) \cdots a^{(n-1)} v^{j_0} b^{j_1} b^{j_2} \cdots b^{j_r} v_{n} [v_{n+1}]^{k_{n+1}} v_{n+1} \cdots \]

(11.2)

We adopt the usual convention (e.g. [RW77]) that for any element \(d\) with \(ed = 0\), \(d^{\circ 0} = [1] - 1_0\), so that \(d^{\circ 0}d = d\) holds. We also set \([v_k]^{=0} = [v_0] = [1]\).

We define it to be allowable or \(Q\)-allowable exactly as in Definition 8.2.

A direct description of the allowable monomials is useful, to replace the indirectness of Definition 8.2. As in [RW96], \(\Delta_0\) denotes the multi-index \((1, 0, 0, \ldots)\).

**Proposition 11.3** Any allowable \(o\)-monomial \(c\) in the Hopf ring can be written uniquely in one of the standard forms

\[
\begin{align*}
(a) \quad & c = a^{l_1} b^{G+L_0} [v^k] & \text{if } c \text{ does not involve } e; \\
(b) \quad & c = e^{o} a^{l_1} b^{G+L-\Delta_0} [v^k] & \text{if } c \text{ involves } e;
\end{align*}
\]

where the multi-index \(G\) is defined by

\[
b^{G} = b^{(p_0)} b^{(p_{n+1})} \cdots b^{(p_{q-1})},
\]

\(L = (l_0, l_1, l_2, \ldots)\), and the indices satisfy

\[
\begin{align*}
(i) \quad & q \geq n; \\
(ii) \quad & 0 \leq d_n \leq d_{n+1} \leq \cdots \leq d_{q-1}; \\
(iii) \quad & 0 \leq l_t < p^r \text{ for all } t < d_r, \text{ for } n \leq r < q; \\
(iv) \quad & 0 \leq l_t < p^q \text{ for all } t; \\
(v) \quad & k_r = 0 \text{ (i.e. } v^k \text{ contains no factor } v_r) \text{ for all } r < q; \\
(vi) \quad & \text{In Case (b), } d_n = 0 \text{ or } l_0 > 0.
\end{align*}
\]

Conversely, any such monomial is allowable.

**Proof** If the allowable monomial \(c\) does not involve \(e\), we choose each \(d_r\) in turn as small as possible, so that (iii) holds; moreover, (iii) requires this choice of \(d_r\). (If we cannot even start, \(q = n, c = a^{l_1} b^{G+L_0} [v^k]\), and (ii), (iii) and (v) become vacuous.) We continue as long as possible, until (iv) holds. In view of (8.3)(i), \(c\) does not contain \([v_r]\) for any \(r < q\), and (v) holds.

If \(c\) has the form \(e^{o} c'\), we note that \(e^{o} c = b_{(0)}^{o} c'\) remains allowable, and apply case (a) to it. Here, we need (vi) so that \(\Delta_0\) can be subtracted off.

Conversely, the monomials \((11.4)\) are easily seen to be allowable.

### The algebra structure

We recall that a *simple system of generators* of a graded algebra \(A\) with multiplication * over a graded ring \(R\) of characteristic \(p\) is a set of elements \(z_1, z_2, z_3, \ldots\) such that the finite products

\[
z^M = z_1^{m_1} * z_2^{m_2} * z_3^{m_3} * \ldots,
\]

(11.7)
where $0 \leq m_r < p$ for each $z_r$ of even degree and $m_r = 0$ or $1$ for each $z_r$ of odd degree, form a set of free $R$-module generators of $A$.

The following description is also essentially included in [RW96, Thms. 1.3, 1.4] [except that for $p = 2$, (d) was not written out explicitly and contains the surprise (iii)]. For $I \neq (1, 1, \ldots, 1)$, $\rho(I)$ denotes the smallest $t$ such that $i_{n-t} = 0$.

**Theorem 11.8** (Ravenel–Wilson) Assume $0 < n < \infty$, and let $k$ be any integer. Then

(a) The Hopf algebra $\overline{P(n)}$ [or $\overline{P(n)}$, if $p = 2$] has as a simple system of $*$-generators the set of all allowable $\circ$-monomials (11.2) (that lie in it);

(b) The $Q$-allowable $\circ$-monomials form a minimal set of algebra $*$-generators of $\overline{P(n)}$, if $p = 2$;

(c) For $p$ odd, $\overline{P(n)}$ is the tensor product of the following subalgebras, one for each $Q$-allowable $\circ$-monomial (that lies in it):

   (i) $TP_{\rho(I)}(a^I \circ b^J \circ [v^K])$ for $I \neq (1, 1, \ldots, 1)$;

   (ii) $P(a^I \circ b^J \circ [v^K])$ for $I = (1, 1, \ldots, 1)$;

   (iii) $E(e \circ a^I \circ b^J \circ [v^K])$;

(d) For $p = 2$, $\overline{P(n)}$ contains the following subalgebras, one for each $Q$-allowable $\circ$-monomial (that lies in it), and is additively (but not multiplicatively) isomorphic to their tensor product:

   (i) $TP_{\rho(I)}(e^{\circ} a^I \circ b^J \circ [v^K])$ for $I \neq (1, 1, \ldots, 1)$;

   (ii) $P(a^I \circ b^J \circ [v^K])$ for $I = (1, 1, \ldots, 1)$;

   (iii) $TP_{n+1}(e \circ a^I \circ b^J \circ [v^K])$ for $I = (1, 1, \ldots, 1)$.

**Remark** For $p = 2$, the quotient algebra

\[ H_*(\overline{P(n)}, \mathbb{F}_2) \cong \mathbb{F}_2 \otimes \overline{P(n)}, \overline{P(n)} \]

is the tensor product of the subalgebras listed in (d), interpreted as $\mathbb{F}_2$-algebras.

To complete this description, we need the structure maps $\circ, \circ, \psi, \epsilon$, and $\chi$, which are all (bi)linear. We know $\psi, \epsilon$, and $\chi$ on each generator $e, a(i), b(j)$ and $[v_k]$; then the Hopf ring laws determine these operations in general.

**Reduction to standard form** We reprove part of Theorem 11.1 by showing that we have enough relations to reduce any Hopf ring expression to a $P(n)_*$-linear combination of $*$-products (11.7) of allowable $\circ$-monomials.

For $\circ$, we need to know how to $\circ$-multiply any two $\circ$-monomials (11.2); then the distributive laws for $(a \circ b) \circ c$ and $a \circ (b \circ c)$ [modified if $p = 2$] take care of general $\circ$-monomials $z^{+M}$ as in (11.7). As the $\circ$-generators $\circ$-commute up to sign [even for $p = 2$], all we need is a reduction formula for each non-allowable $\circ$-monomial (11.2).

The relation $\circ \circ c = -b(0)$ takes care of $e^{\circ 2}$. If $p$ is odd, $a^{\circ 2}(i) = 0$ is automatic, by Proposition 10.13(i). [If $p = 2$, we use $a^{\circ 2}(i) = b(i+1)$ instead, from equation (10.18).]
For the disallowed monomials (i) and (ii) of (8.3), we use the same relations as in Lemma 8.5, now working modulo $\ast$-decomposables as well. These use only the relations $(\mathcal{R}_k)$ for $k > n$ and (10.10), which implies $(\mathcal{R}_n)$.

For the $\ast$-product of two $\ast$-monomials (11.7), we shuffle the $\circ$-monomials into the desired order (with the appropriate sign), and deal with excess $\ast$-powers of any $\circ$-monomial. [If $p = 2$, shuffling introduces extra terms, but the process quickly terminates, because the $\ast$-commutator $c \ast d - d \ast c$ of any two $\circ$-monomials is $\ast$-central; see [Bo] for details.]

The Frobenius operator To finish the reduction to standard form, we need a formula for the Frobenius operator $F_c = c^{\ast p} = c \ast c \ast \ldots \ast c$ on each allowable $\circ$-monomial $c$ of even degree [or any degree if $p = 2$].

We start from the relation $[1]^{\ast p} = 1_0$, which we rewrite as $F(\left[ 1 \right] - 1_0) = 0$. We next reverse the identity [BJW95, (15.13)] as

$$F(c \circ b^J) = (F_c) \circ b^{0,J},$$

where $0, J$ denotes the extended multi-index $(0, j_0, j_1, j_2, \ldots)$. The proof used only the property $\psi b_k = \sum_{i+j=k} b_i \otimes b_j$. Since $a_k$ has the same property when $p$ is odd, according to Proposition 10.16(b), we similarly have

$$F(a^{\circ I,0} \circ c) = a^{\circ 0,I} \circ F_c$$

for any multi-index $I = (i_0, i_1, i_2, \ldots, i_{n-2})$. [For $p = 2$, Proposition 10.16 delivers the same result, and also

$$F(e \circ c) = a(0) \circ F_c.$$]

For $a_{(n-1)}$, we rewrite the relation (10.14) as

$$F a_{(n-1)} = v_n a_{(0)} - a_{(0)} \circ b^n_{(0)} \circ [v_n].$$

Since applying $-\circ [v^K]$ preserves $\ast$-multiplication, we immediately have

$$F(c \circ [v^K]) = (F_c) \circ [v^K].$$

Combining these, we find the general formulae

$$F(a^{\circ I,0} \circ b^{\circ J} \circ [v^K]) = 0$$

and (with attention to the shuffles needed and the resulting signs)

$$F(a^{\circ I,1} \circ b^{\circ J} \circ [v^K]) = (-1)^{|I|+1} a^{\circ 1,I} \circ b^{N,J} \circ [v_n v^K] + (-1)^{|I|} v_n a^{\circ 1,I} \circ b^{0,J} \circ [v^K],$$

where $|I| = \sum_i i_r$.

[If $p = 2$, we need also the formulae involving $e$, which are

$$F(e \circ a^{\circ 1,0} \circ b^{\circ J} \circ [v^K]) = 0$$

and

$$F(e \circ a_{(0)} \circ a_{(n-1)} \circ b^{\circ N}_{(0)} \circ [v^K]) = b^{N+2^{n+1}}_{(0)} \circ [v_{n+1}] + v_n b^{2^n}_{(1)} + v_n b^{2^n}_{(0)} b_{(1)} + v_{n+1} b^{2^n}_{(0)}$$

after reduction to standard form, which recovers equation (7.21).]
A reduction formula There is a difficulty with equation (11.11) which obscures the algebraic structure of the Hopf ring. Even in the simple case
\[ F(a_{n-1} \circ b^G) = -a_{0} \circ b^{N,G} \circ [v_{n}] + v_{n} a_{0} \circ b^{-0,G}, \]
with \( G \) as in equation (11.5), the first term on the right is visibly not allowable (unless \( q = n \), so that \( G = 0 \)). What we need is a reduction formula for
\[ b^{0,G} \circ [v_{n}] = b^{p_{n}}(d_{n+1}) \circ b^{p_{n+1}}(d_{n+1+1}) \circ \ldots \circ b^{p_{r-1}}(d_{r-1+1}) \circ [v_{n}], \]
which is essentially Lemma 3.8 of [RW96]. It involves the \( p \)-th \( \circ \)-power of \( b^G \),
\[ (b^G)^{\circ p} = b^{p_{n+1}}(d_{n}) \circ b^{p_{n+2}}(d_{n+1}) \circ \ldots \circ b^{p_{r}}(d_{r-1}). \]

**Lemma 11.14** Using only the main relations \((\mathcal{R}_{k})\), the \( \circ \)-monomial \( b^{0,G} \circ [v_{n}] \), with \( G \) as in equation (11.5), reduces to an allowable monomial by a formula of the form
\[ b^{0,G} \circ [v_{n}] \equiv (-1)^{q-n} b^{pG} [v_{q}] + \ldots, \]
where the omitted terms do not involve any \( a_{(i)} \) and either (i) have the form \( b^{J} \circ [v_{k}] \) with \( b^{J} \) lexicographically higher than \( b^{pG} \) (see §8), (ii) lie in the ideal \( \mathfrak{Z} = (v_{n}, v_{n+1}, \ldots) \), (iii) have \([v]\)-length at least 2, or (iv) are \( \ast \)-decomposable.

We apply this to equation (11.11) [also (11.13) if \( p = 2 \)].

**Corollary 11.15** For the general allowable \( \circ \)-monomial (11.4)(a) without \( e \), we have
\[ F(a^{sL} \circ b^{N,L} \circ [v^K]) \equiv (-1)^{q-n+|l|+1} a^{sL} \circ \{ b^{N,L,G} \circ [v_{q} v^{K}] + \ldots \} \]  

[11.16]

[If \( p = 2 \), we similarly obtain
\[ F(e \circ a^{sL} \circ b^{N,L,G} \circ [v^K]) \equiv a^{sL} \circ \{ b^{N,L,G} \circ [v_{q} v^{K}] + \ldots \} \]  

from (11.4)(b).] \( \square \)

The leading term on the right in equation (11.16) is always allowable: written in standard form (11.4), it is \( a^{sL} \circ b^{G+L} \circ [v^K] \), with the same \( G, v^{K} = v_{q} v^{K} \), and \( b^{L'} = b^{N,L} \circ b^{(p-1)G} \). Careful bookkeeping shows that, as the indices vary, it runs through all the \( Q \)-disallowed \( \circ \)-monomials of type (8.3)(iii) that are nevertheless allowable, once each. [Similarly, (11.17) accounts for types (iv) and (v).]

It follows that \( F \) never kills anything unexpected. Now we can read off parts (c) and (d) of Theorem 11.8.

**Proof of Lemma** For \( n \leq r \leq q \), we set \( c_{r} = b^{p_{n+1}}(d_{n}) \circ b^{p_{n+2}}(d_{n+1}) \circ \ldots \circ b^{p_{r}}(d_{r-1}) \), so that (conventionally) \( c_{n} = b^{0} \) and \( c_{q} = b^{pG} \).

We show first that \( c_{r} \circ [v_{n}] = 0 \) whenever \( n \leq s < r \leq q \), by induction on \( s \). We \( \circ \)-multiply \((\mathcal{R}_{d_{n}+s})\) by \( c_{s} \); by (7.14), the \( k \)-th term is \( c_{s} \circ b^{p_{k}}(d_{s}+s-k) \circ [v_{k}] \). If \( k < s \), this term is neglected by induction. (If \( s = n \), there are no such terms.) If \( k > s \), we have \( d_{s} + s - k < d_{s} \), and this term is lexicographically higher. If \( k = s \), we have \( c_{s} \circ b^{p_{s}}(d_{s}) \circ [v_{s}] \), which gives \( c_{s+1} \circ [v_{s}] = 0 \) when we \( \circ \)-multiply by \( b^{p_{s+1}} \); hence \( c_{r} \circ [v_{s}] = 0 \) for any \( r > s \), if we \( \circ \)-multiply by further factors.
Then we show that $c_s b^{\partial_{(d_s+1)}}_{(d_s+1)} \circ [v_s] \equiv -c_{s+1} \circ [v_{s+1}]$ for $n \leq s < q$, from which the result follows by induction, starting from $c_n = b^0$. We $o$-multiply $(R_{d_s+1})$ by $c_s$. The $k$-th term is $c_s b^{\partial_{(d_s+1)-k}}_{(d_s+1)-k} \circ [v_k]$, which we have just shown is negligible if $k < s$. If $k > s + 1$, we have $d_s + s + 1 - k < d_s$, and the term is lexicographically higher. The two remaining terms, with $k = s$ and $k = s + 1$, are the desired terms. \hfill \square

### §12 Effect on homotopy groups

Given an unstable operation $r: P(n)^k(-) \to P(n)^m(-)$, where $k, m > 0$, consider the homomorphism of homotopy groups $r_*: \Sigma^k P(n)_* \to \Sigma^m P(n)_*$ (see diagram (3.9)) induced by the representing map $r: P(n)_k \to P(n)_m$. By [BJW95, Lemma 13.9], it is given on $\Sigma^k v$, where $v \in P(n)_*$, by the unstable analogue of equation (7.6), namely

$$r_* \Sigma^k v = \Sigma^m \langle r, e_{k+1} \circ [v] \rangle,$$

(12.1)

where $e_{2j} = b^j_{(0)}$ and $e_{2j+1} = e \circ b^j_{(0)}$.

We therefore seek more information on the relations in the Hopf ring.

**The first higher-order relation** We need the Hopf ring version for $P(n)$ of Bendersky’s Lemma [Be86, Thm. 6.2], which immediately implies Lemma 8.12.

**Lemma 12.2** For $q \geq n$, we have in $P(n)_*((P(n)_{g(n,q-1)} - 1)_{g(n,q-1)+1})$ the reduction formula

$$e_{g(n,q)-1 \circ [v_q]} \equiv v_q e_{g(n,q)-1 \circ [v_q]} \mod I_q P(n)_*((P(n)_{g(n,q-1)} - 1)_{g(n,q-1)+1}).$$

(12.3)

*If $p = 2$, this is almost superseded by

$$e_{g(n,q)-2 \circ [v_q]} \equiv v_q e_{g(n,q)-1 \circ [v_q]} + F(e_{g(n,q)-1 \circ [v_q]} \circ a(n-1)) \mod I_q,$$ for $q \geq n + 1$. \hfill (12.4)

**Proof** We establish (12.3) by induction on $q$. For $q = n$, it follows immediately from (10.10). For $q > n$, we return to the definition of the relation $(R_q)$. We expand $[p] = \sum_K \lambda(K) v^K \cdot d(K)$, summing over multi-indices $K$, with coefficients $\lambda(K) \in F_p$ and exponents $d(K)$; then if we write $b(x) = 1_2 + b(x)$, (10.8) becomes

$$1_2 + \overline{b} \left( \sum_K \lambda(K) v^K x^{d(K)} \right) = \bigstar \left\{ 1_2 + \overline{b} (x) \circ d(K) \circ [v^K] \right\} \circ \lambda(K).$$

(12.5)

We apply the suspension $e_h \circ -$, where $h = g(n, q-1) - 1$, which kills $1_2$ and most $\ast$-products and thus drastically simplifies (12.5) to

$$e_h \circ \overline{b} \left( \sum_K \lambda(K) v^K x^{d(K)} \right) = \sum_K \lambda(K) e_h \circ \overline{b} (x) \circ d(K) \circ [v^K].$$

We take the coefficients of $x^{p_q}$ and work mod $I_q$. On the left, by (6.18), the only surviving term in $[p] = v_q x^{p_q}$, giving $e_h \circ v_q b(0)$, the right side of (12.3). On the right, $e_h \circ [v_k] \equiv 0$ for all $k < q$, by induction on $q$, since $h = g(n, q-1) - 1 \geq g(n, k) - 1$. This leaves only $e_h \circ b^{p_q}_{(0)} \circ [v_q]$, as required.

[For (12.4), we take $h = g(n, q-1) - 2$ instead. We still have enough $e$’s to kill $[v_k]$ for any $k < q - 1$, but not $[v_{q-1}]$. By (6.16), the only terms of interest in $[2](x)$ are $v_{q-1} x^{2q-1}$ and $v_q x^{2q}$. Instead of (12.3), we find

$$e_h \circ v_q b(0) = e_h \circ b^{2q-1}_{(1)} \circ [v_{q-1}] + e_h \circ b^{2q}_{(0)} \circ [v_q].$$

(12.6)
The first and third terms appear as the second and first terms in (12.4).

The second term is not allowable; but if \( q = n + 1 \), we use (11.13) to write it as

\[ b_{(0)}^{N} o b_{(1)}^{2g-1} o [v_{n}] \equiv F(e o a(n-1) o b_{(0)}^{N}). \]

If \( q > n + 1 \), we have \( e_{h} o [v_{q-1}] \equiv F(e(a(n,q-2)-1 o a(n-1))) \) by induction. Then

\[ e_{h} o b_{(1)}^{2q-1} o [v_{q-1}] \equiv b_{(1)}^{2q-1} o F(e(a(n,q-2)-1 o a(n-1))) = F(b_{(0)}^{2q-1} o e(a(n,q-2)-1 o a(n-1))), \]

as required, with the help of equation (11.9). [ \( \square \) ]

\section*{Proofs for §3} Now we can finish the proofs of two lemmas.

\textit{Proof of Lemma 3.8} For (a), by (12.1),

\[ r_{*} \Sigma^{k}(v_{n}v) = \Sigma^{m}[r, e_{k+q+2N} o [v_{n}v]] = \Sigma^{m}[r, e_{k+q+2N} o [v_{n}] o [v]]. \]

Since \( k + q > 0 \), we can use (10.10) to rewrite this as

\[ r_{*} \Sigma^{k}(v_{n}v) = \Sigma^{m}[r, v_{n} e_{k+q} o [v]] = v_{n} r_{*} \Sigma^{k} v. \]

Part (b) is similar, with (12.3) in place of (10.10). [ \( \square \) ]

\textbf{Lemma 12.6} Let \( r: P(n)_{k} \rightarrow P(n)_{k} \) be any map, where \( k > g(n,m-1) \), and suppose that on homotopy, \( r_{*} \Sigma^{k} P(n)_{*} \rightarrow \Sigma^{k} P(n)_{*} \) is given on the bottom class by \( r_{*} \Sigma^{k} 1 = \lambda \Sigma^{k} 1 \), where \( \lambda \in \mathbb{F}_{p} \). Then on any monomial \( v^{K} \) in the elements \( v_{n}, v_{n+1}, \ldots, v_{m}, r_{*} \)

has the form

\[ r_{*} \Sigma^{k} v^{K} = \lambda \Sigma^{k} v^{K} + \sum_{L > K} c_{L} \Sigma^{k} v^{L} \quad (12.7) \]

with coefficients \( c_{L} \in \mathbb{F}_{p} \), where we order the multi-indices \( L = (l_{n}, l_{n+1}, \ldots) \) lexicographically (as in §8).

\textit{Proof} We use induction on the length of \( v^{K} \), starting from \( K = 0 \). If (12.7) holds for \( \Sigma^{k} v^{K} \), Lemma 3.8(b) gives

\[ r_{*} \Sigma^{k}(v_{q} v^{K}) \equiv \lambda \Sigma^{k}(v_{q} v^{K}) + \sum_{L > K} c_{L} \Sigma^{k}(v_{q} v^{L}) \mod I_{q}. \]

If we assume (as we may) that \( v^{K} \) contains no factors \( v_{t} \) with \( t < q \), all monomials in \( I_{q} \) will be larger lexicographically than \( v_{q} v^{K} \), and we have the result for \( v_{q} v^{K} \). [ \( \square \) ]

\textit{Proof of Lemma 3.6} Take any map \( f: P(n,m)_{k} \rightarrow P(n,m)_{k} \), where \( g(n,m-1) < k \leq g(n,m) \). Suppose \( f_{*} \Sigma^{k} 1 = \lambda \Sigma^{k} 1 \). We apply Lemma 12.6 to the composite

\[ P(n)_{k} \xrightarrow{\rho(m)} P(n,m)_{k} \xrightarrow{f} P(n,m)_{k} \xrightarrow{\theta(m)} P(n)_{k} \]

to deduce that

\[ \theta(m) f_{*} \Sigma^{k} v^{K} = \lambda \Sigma^{k} v^{K} + \sum_{L > K} c_{L} \Sigma^{k} v^{L} \]

for any monomial \( v^{K} \) in the generators \( v_{n}, v_{n+1}, \ldots, v_{m} \). We apply \( \rho(m)_{*} \), to see that \( f_{*} \Sigma^{k} v^{K} \) has the same form (possibly with some terms \( v^{L} \) deleted). It is now clear that if \( \lambda \neq 0 \), \( f_{*} \) is an isomorphism and \( f \) is a homotopy equivalence. [ \( \square \) ]
